   When the CMWCNT counter value is transferred to CMWICR1 using the input capture operation, the CMWCNT counter is cleared to 0000 0000h.
   The CMWCNT counter then restarts counting up from 0000 0000h.
3. When CMWCR.CCLR[2:0] ≠ 100b or 101b
   Even when the CMWCNT counter value is transferred to CMWICR0 or CMWICR1 using the input capture operation, the CMWCNT counter is not cleared to 0000 0000h but continues counting up until the clearing condition set in CMWCR.CCLR[2:0] is satisfied or the value of the counter reaches FFFF FFFFh (when the size of the counter is 32 bits) or ****FFFFh (when the size of the counter is 16 bits). The CMWCNT counter is then cleared to 0000 0000h and restarts counting up from 0000 0000h.

Figure 25.7 shows an example of procedure for setting input capture operation.

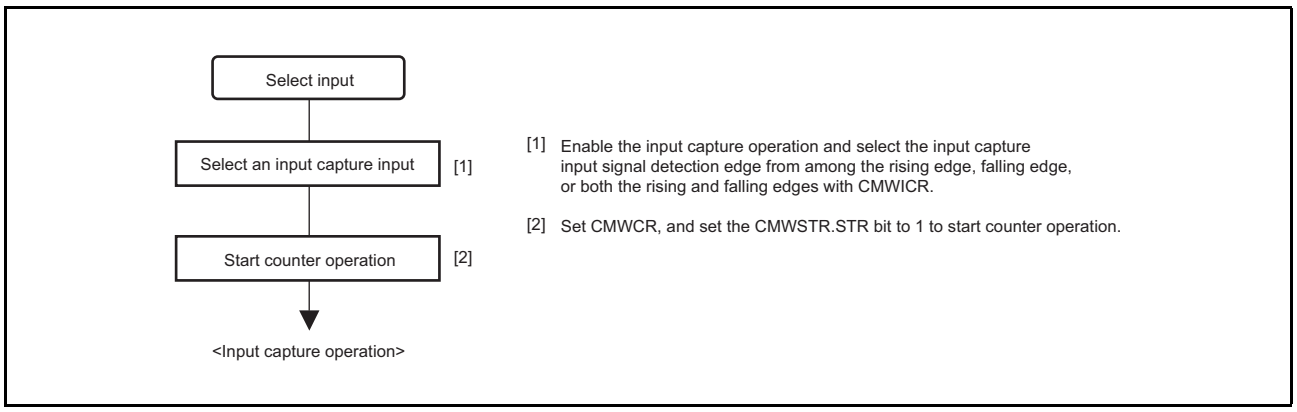

Figure 25.7 Procedure for Setting Input Capture Operation

Figure 25.8 shows an example in which both the rising and falling edges are selected for the TIC0 pin input capture input edge and the falling edge for the TIC1 pin, and the CMWCNT counter is cleared by a CMWICR1 register input capture.

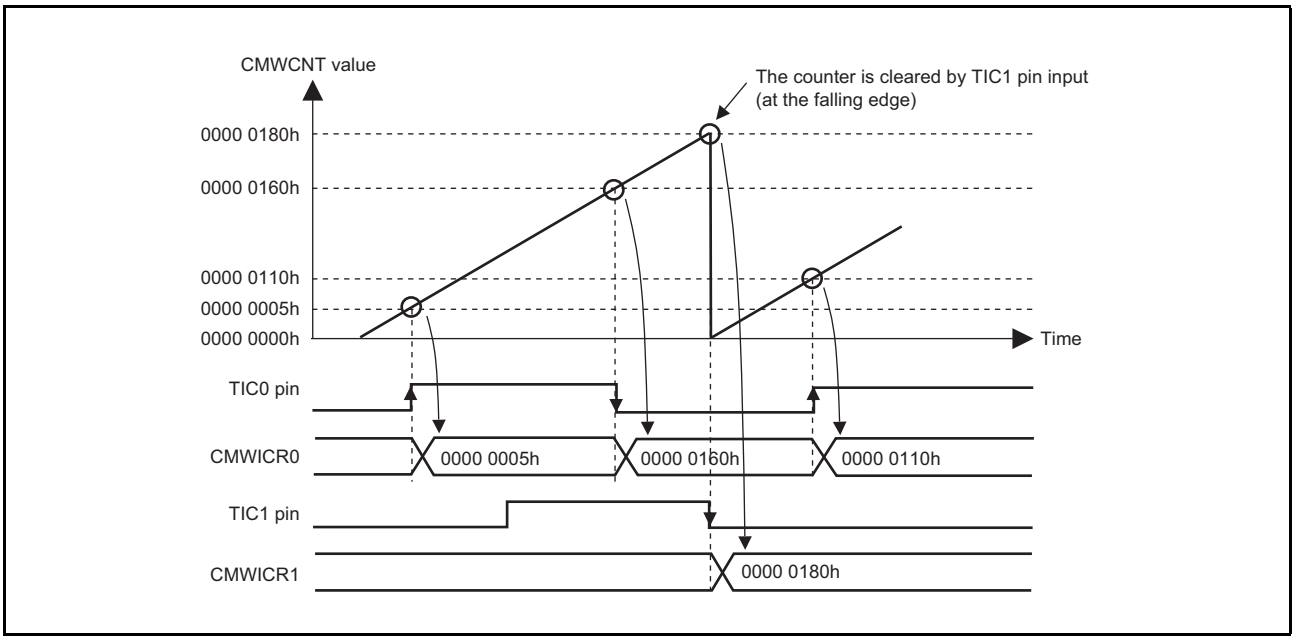

Figure 25.8 Example of Input Capture Operation

25.3.5 Counter Size

With the CMTW, either 16 or 32 bits can be selected as the counter size by using the CMWSTR.CMS bit. When the counter is used as a 32-bit counter, set the CMWCOR, CMWOCR0, or CMWOCR1 register to the desired values in 32-bit units. In reading, all 32 bits of CMWICR0 and CMWICR1 are valid. When the counter is used as a 16-bit counter, a 32-bit value should be set to the CMWCOR register with 0000h in the higher-order bits. Similarly, a 32-bit value should be set to CMWOCR0 and CMWOCR1 registers with 0000h in the higher-order bits.
A 32-bit value with 0000h in the higher-order bits is read from CMWICR0 and CMWICR1 registers.

25.3.6 Count Timing based on CMWCNT

One of four clocks (PCLKD/8, PCLKD/32, PCLKD/128, and PCLKD/512) obtained by dividing the peripheral clock (PCLKD) can be selected with the CMWCR.CKS[1:0] bits. Figure 25.9 shows the timing.

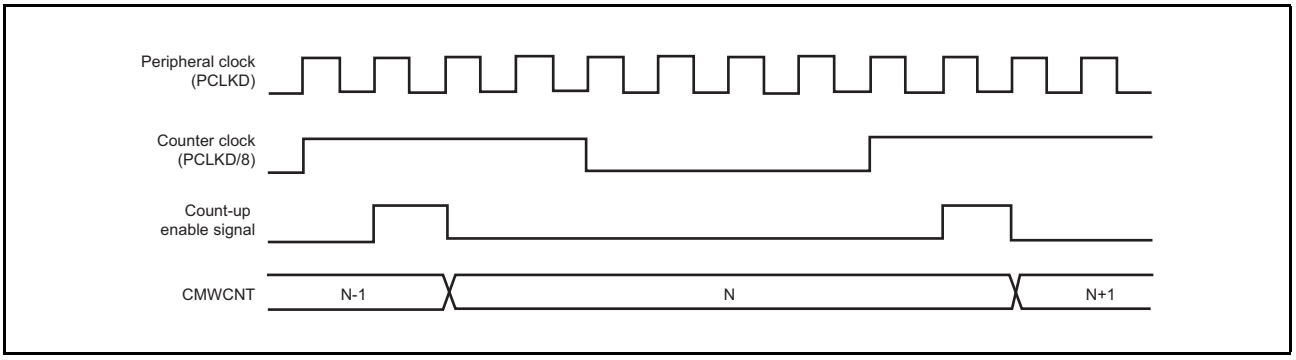

Figure 25.9 Count Timing (PCLKD/8)

25.3.7 Output Compare Output Timing

A compare match signal is generated in the last state in which the CMWOCR register and CMWCNT counter values match (the CMWCNT counter value is updated immediately after the state). That is, the compare match signal is not generated if the CMWCNT counter clock is not input after a match between the CMWOCR register and CMWCNT counter values. When a compare match signal is generated, the output compare output pin (TOC) changes in accord with the setting of the OC0 or OC1 bit in the CMWIOR register. Figure 25.10 shows output compare output timing.

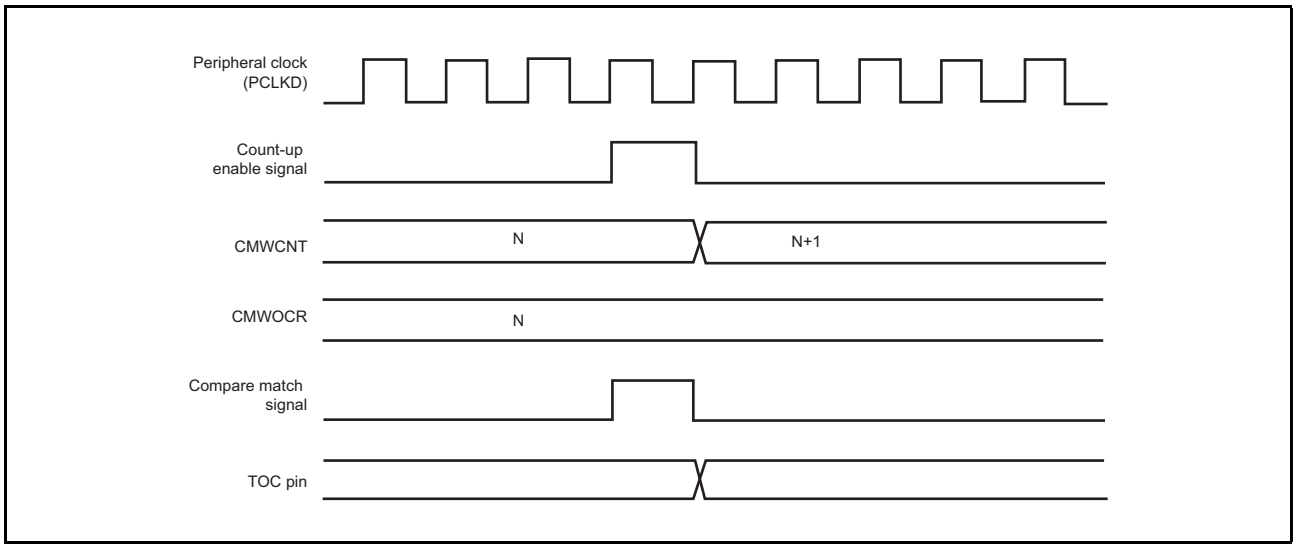

Figure 25.10 Output Compare Output Timing

25.3.8 Input Capture Signal Timing

Figure 25.11 shows the input capture timing.

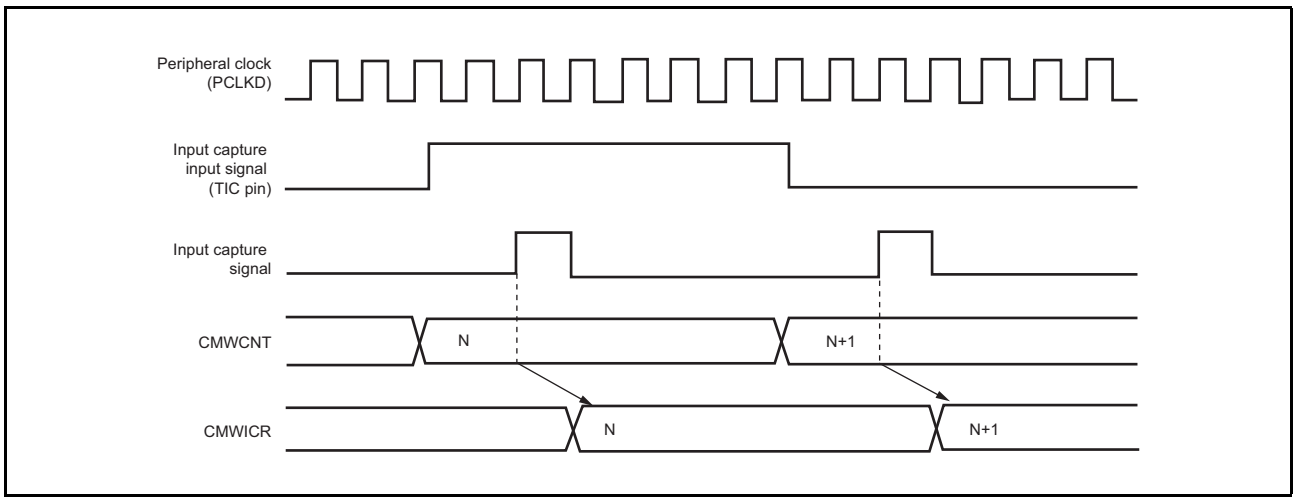

Figure 25.11 Input Capture Input Signal Timing

25.3.9 Digital Noise Filtering

The noise filter samples CMTW input-capture signals at the frequency of the sampling clock and the pulses with levels that only match once or twice are removed.
The digital noise filtering functionality includes enabling and disabling of the noise filtering for each pin. Figure 25.12 shows the timing of digital noise filtering.

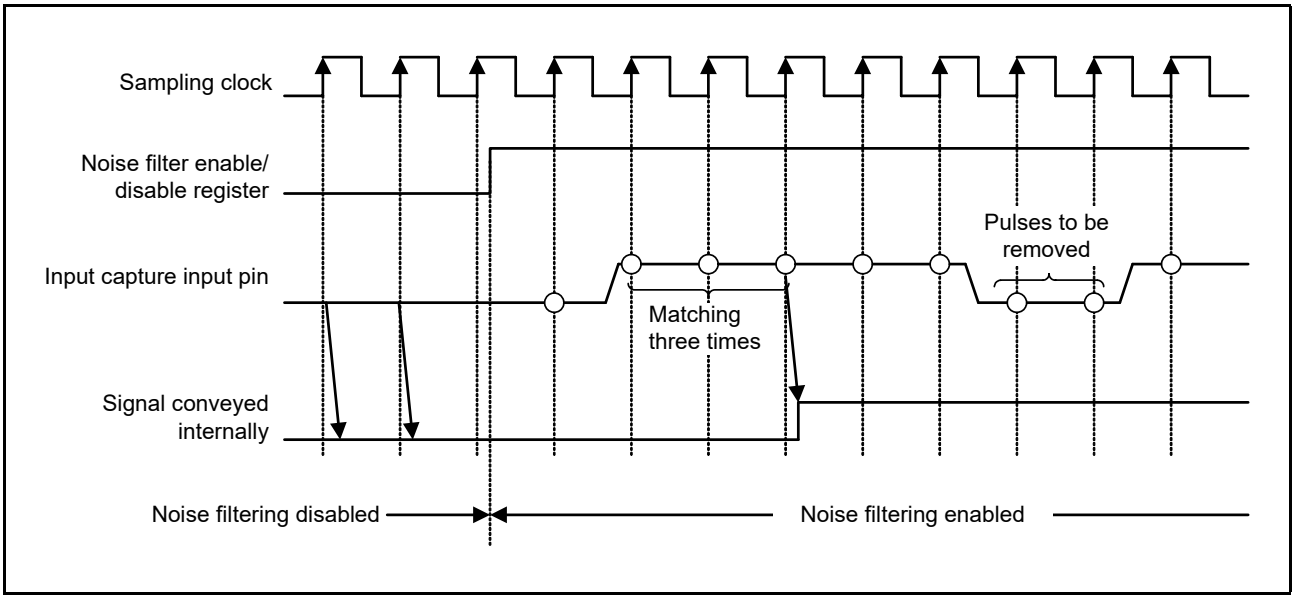

Figure 25.12 Timing of Digital Noise Filtering

If digital noise filtering is enabled, input capture proceeds on edges of the noise filtered signal after a delay of (minimum sampling interval × 2 + PCLKD) due to noise filtering of the input capture input.

25.3.10 ECM Dynamic Mode Error Output Selection

This LSI, uses an output compare signal of CMTW as an error output signal in ECM dynamic mode. That is, one of the CMTW output compare signals is selected as the error output in ECM dynamic mode.
When an actual output compare signal of CMTW is to be output to the ECM, set up the output comparison for the CMTW channels to be used in this way before setting the ECDMESLR register.
For the procedure for setting up output comparison, see section 25.3.3, Output Compare Function.
For details of ECM dynamic mode, see section 42, Error Control Module (ECM).

25.4 Interrupts

25.4.1 CMTW Interrupt Sources and DMAC Transfer Requests

The CMTW has five interrupt sources: two input capture interrupt requests (IC0In and IC1In), two output compare interrupt requests (OC0In and OC1In), and a compare match interrupt request (CMWIn) (n = 0, 1).
Table 25.3 shows the interrupt sources and priority. The interrupt sources can be enabled or disabled using the IC0IE, IC1IE, OC0IE, OC1IE, and CMWIE bits in CMWCR and are separately issued to the interrupt controller.

Table 25.3 CMTW Interrupt Sources

Interrupt Source	Interrupt	Interrupt Enable Bit	DMAC Activation	Priority
CMWIn	Interrupt caused by compare match	CMWIE	Possible	High
IC0In	Interrupt caused by input capture 0	IC0IE	Possible	
IC1In	Interrupt caused by input capture 1	IC1IE	Possible	
OC0In	Interrupt caused by output compare 0	OC0IE	Possible	
OC1In	Interrupt caused by output compare 1	OC1IE	Possible	Low

25.4.2 Timing of Compare Match Interrupt Generation

When the values of the CMWCNT counter and CMWCOR register match, a compare match interrupt (CMWI) is generated. The compare match signal is generated at the end of the cycle where the values matched (i.e. when the CMWCNT counter is updated from the matching counter value). The compare match signal, therefore, is not generated until a further cycle of the input clock (PCLKD/8, PCLKD/32, PCLKD/128, or PCLKD/512) for the CMWCNT counter arrives after the values of the CMWCNT counter and CMWCOR register have matched. Figure 25.13 shows the timing of compare match interrupt generation.

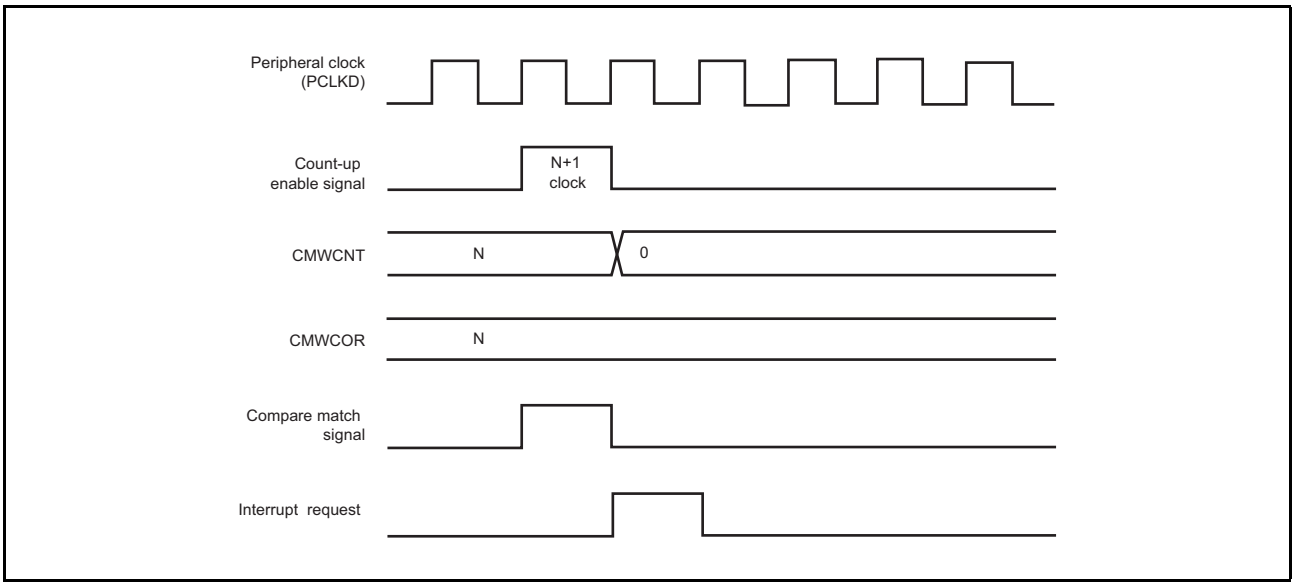

Figure 25.13 Timing of Compare Match Interrupt Generation

25.4.3 Timing of Output Compare Interrupt Generation

Figure 25.14 shows the timing of output compare interrupt generation.

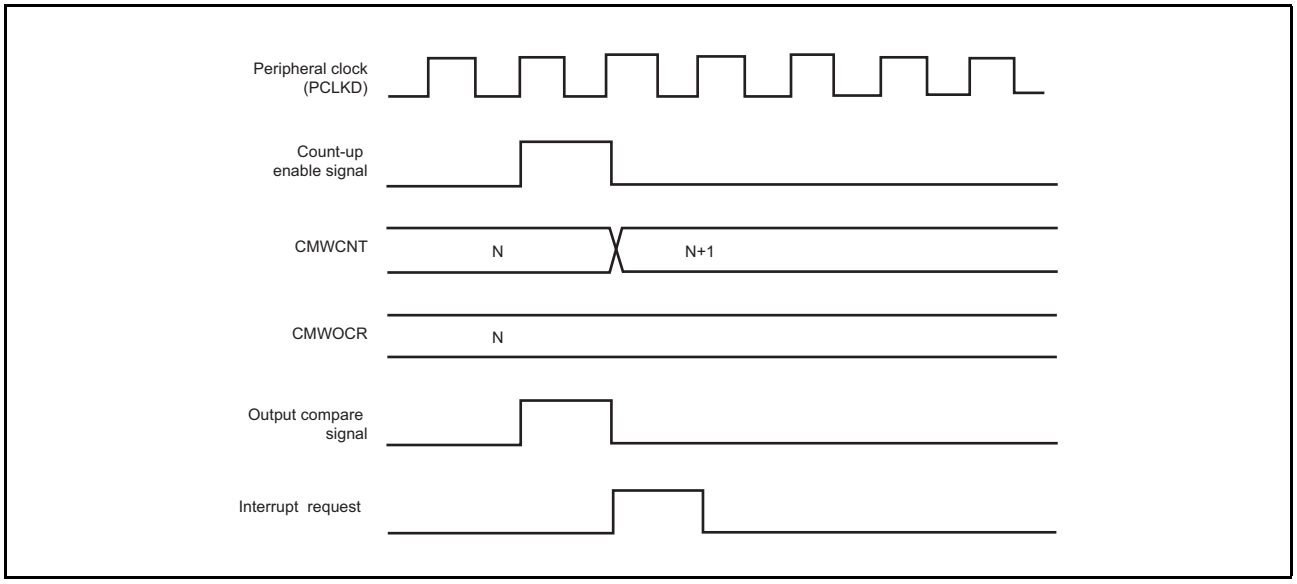

Figure 25.14 Timing of Output Compare Interrupt Generation

25.4.4 Timing of Input Capture Interrupt Generation

Figure 25.15 shows the timing of input capture interrupt generation.

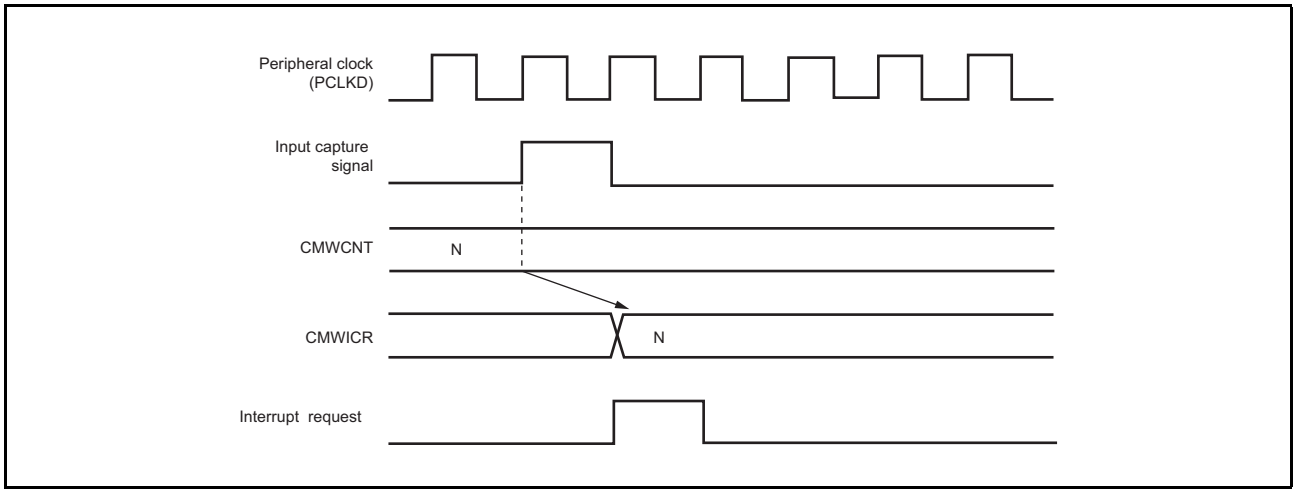

Figure 25.15 Timing of Input Capture Interrupt Generation

25.5 Event Link Operation

25.5.1 Issuing Events to the ELC

The CMTW can issue event signals to the event link controller (ELC) in response to the following events.

Compare Match Event

In response to a compare match, the CMTW simultaneously issues an interrupt request and a compare match event signal to the ELC. The event signal is issued regardless of the settings of the corresponding interrupt request enable bit (CMWCR.CMWIE bit).

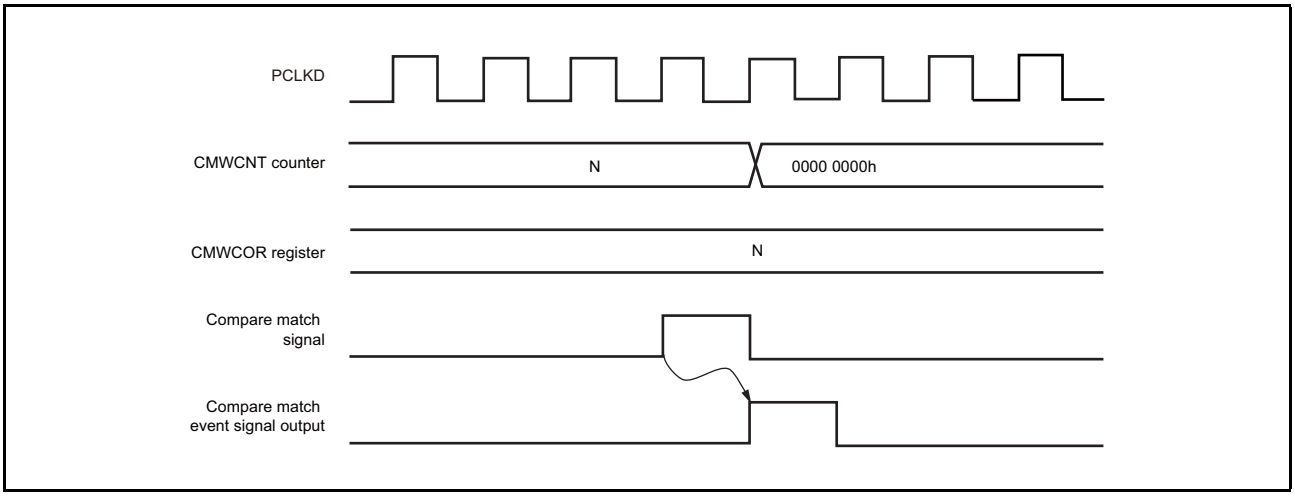

Figure 25.16 Timing of Issuing a Compare Match Event Signal

25.5.2 Actions on Acceptance of Event Signals from ELC

CMTW can respond with any of the following three actions when the action is set in the event link controller (ELC) and CMTW accepts the event signal.

(1) Start Counting

When an event signal is received while starting to count is the selected action, the STR bit in CMWSTR (the timer start register) is set to 1 and counting starts.

However, the event signal is ignored if it is accepted when the CMWSTR.STR bit has already been set to 1.

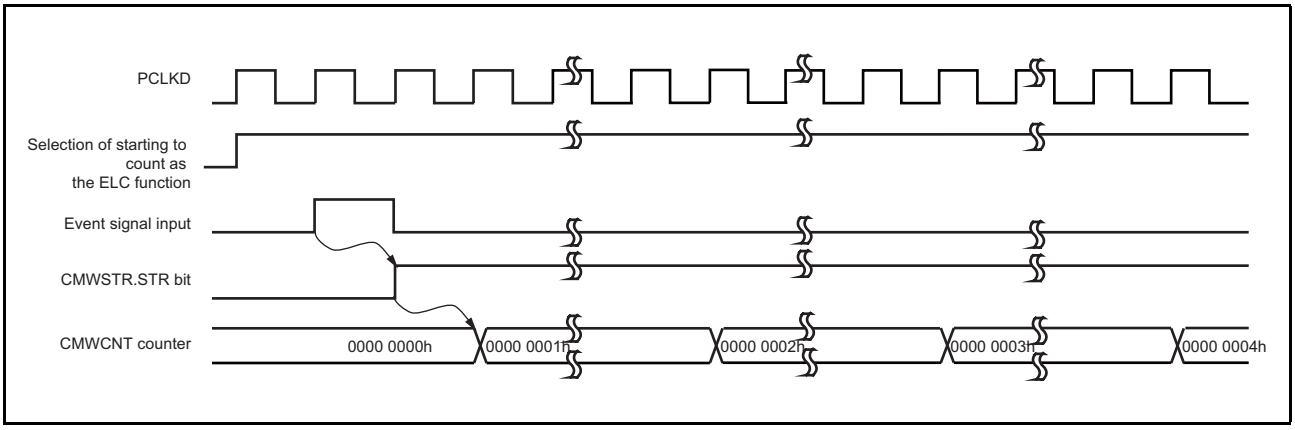

Figure 25.17 Starting to Count on Acceptance of the Event Signal

(2) Event Counting

When an event signal is received while counting events is the selected action, CMWCNT (the timer counter) is incremented. In this case, however, the STR bit in CMWSTR (the timer start register) must be set to 1 before the event signal is received.

In event counting, the setting of the CKS[1:0] bit in CMWCR (the timer control register) is not effective.

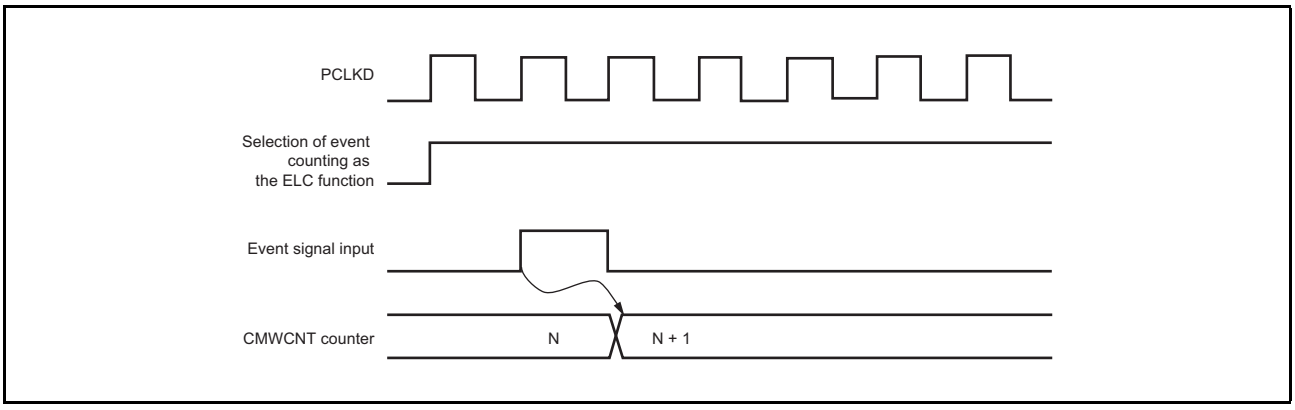

Figure 25.18 Counting an Event on Acceptance of the Event Signal

(3) Clear a Counter

Clearing of the CMTW counter is selected in the ELOPH register of the ELC. When the event specified in the corresponding ELSRn register is generated, the timer counter (CMWCNT) is returned to its initial value (0000h). Counting continues, however, if the setting of the STR bit of the timer start register (CMWSTR) is 1 at this time, so counting can be automatically restarted in this way. A timing chart of restarting the counter is shown in Figure 25.19

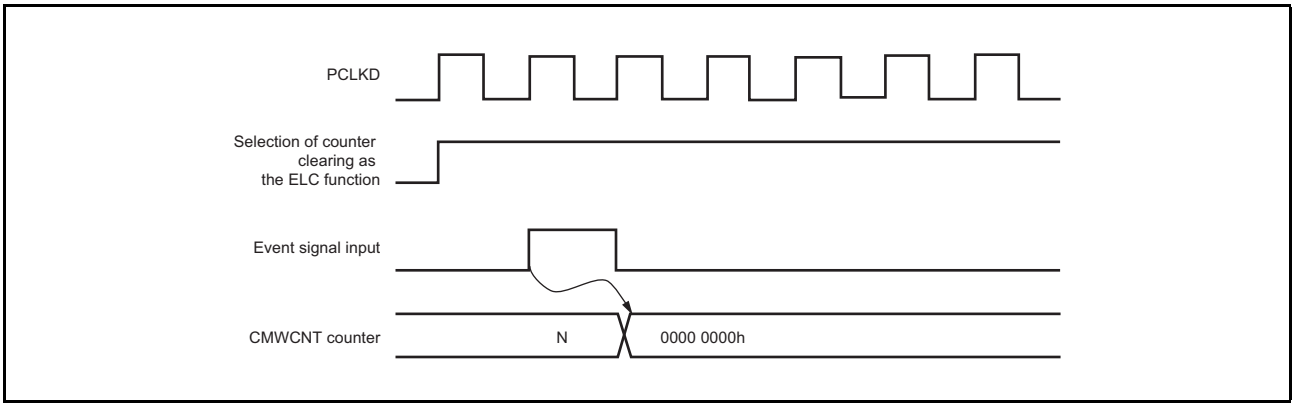

Figure 25.19 Restarting Counting on Acceptance of the Event Signal

25.6 Usage Notes

25.6.1 Module-Stop Function

The CMTW operation can be enabled or disabled by using the module-stop control register (MSTPCRA). In the initial setting, the CMTW is in the module-stop state. Register access is enabled by releasing the CMTW from the module-stop state. For details, refer to section 9, Low-Power Consumption Function.

25.6.2 Contention between CMWCNT Counter Writing and Compare Match

If the compare match signal is generated during CPU writing to the CMWCNT counter, the compare match request is output but the counter is not cleared since the CPU writing to the counter is given priority.
Figure 25.20 shows the timing of contention between CMWCNT counter writing and compare match.

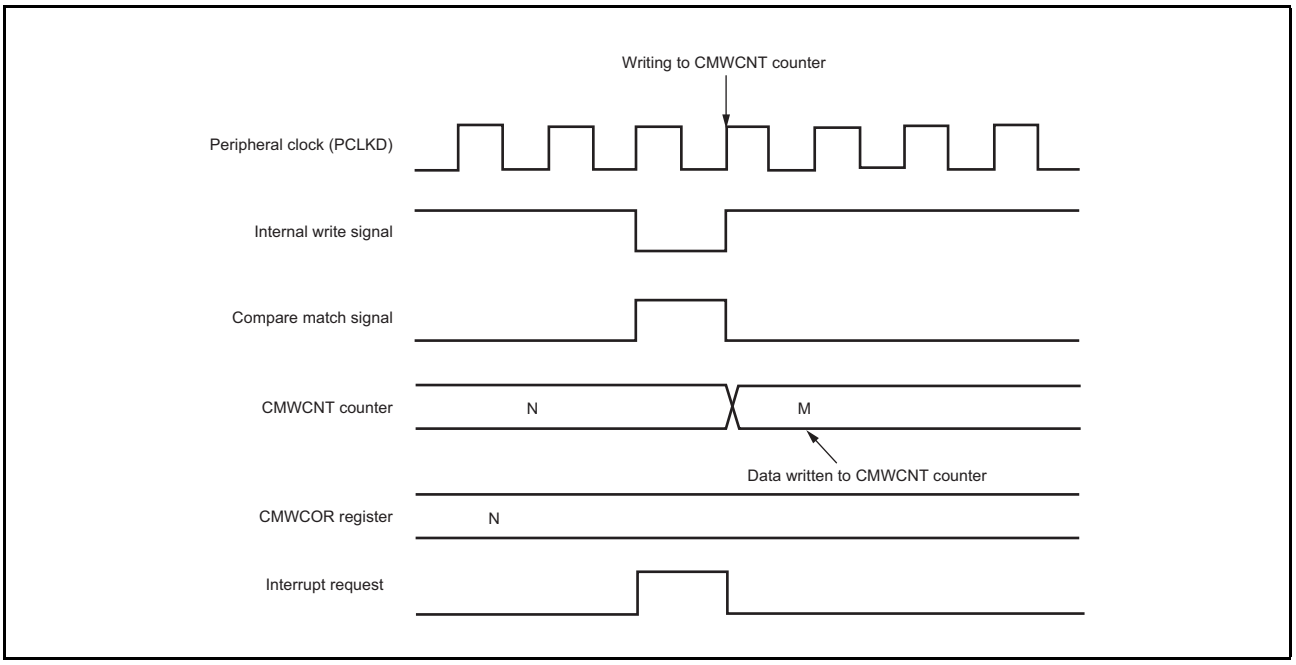

Figure 25.20 Contention between CMWCNT Counter Writing and Compare Match

25.6.3 Contention between CMWCNT Counter Writing and Incrementing or Clearing

In case of contention between incrementation or clearing of the CMWCNT counter and CPU writing to the counter, the counter is not actually incremented or cleared since the CPU writing to the CMWCNT counter is given priority.
Figure 25.21 shows the timing in the case of contention between writing to the CMWCNT counter and incrementation or clearing.

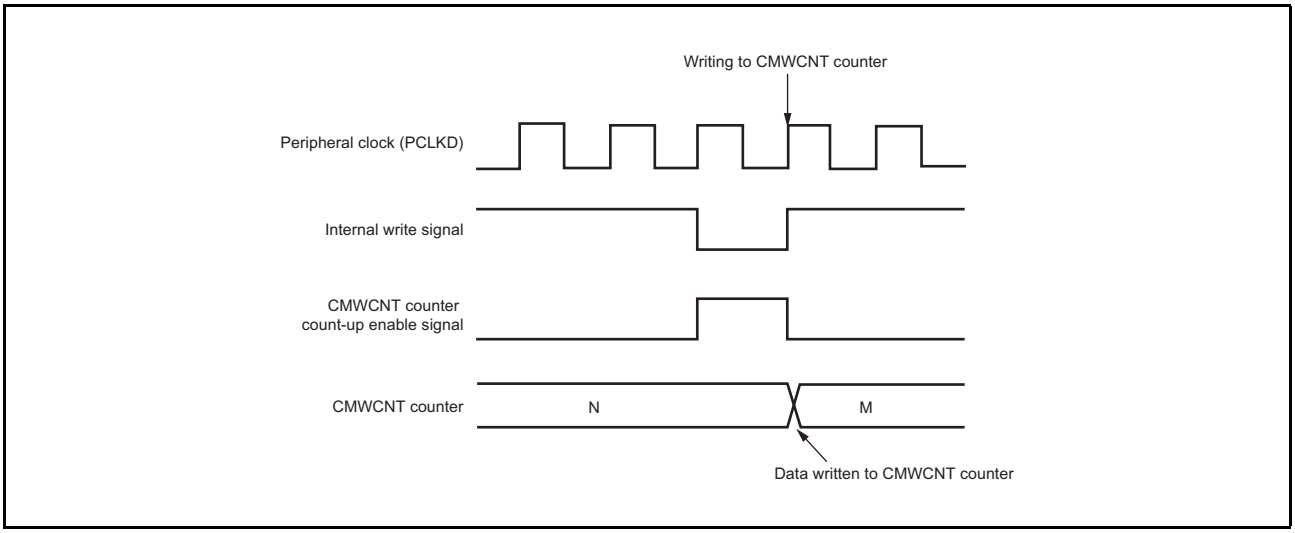

Figure 25.21 Contention between CMWCNT Counter Writing and Incrementing

25.6.4 Contention between CMWCOR Register Writing and Compare Match

If the compare match is generated during CPU writing to the CMWCOR register, the CPU writing to the CMWCOR register proceeds and also the compare match signal is output.
Figure 25.22 shows the timing of contention between CMWCOR register writing and compare match.

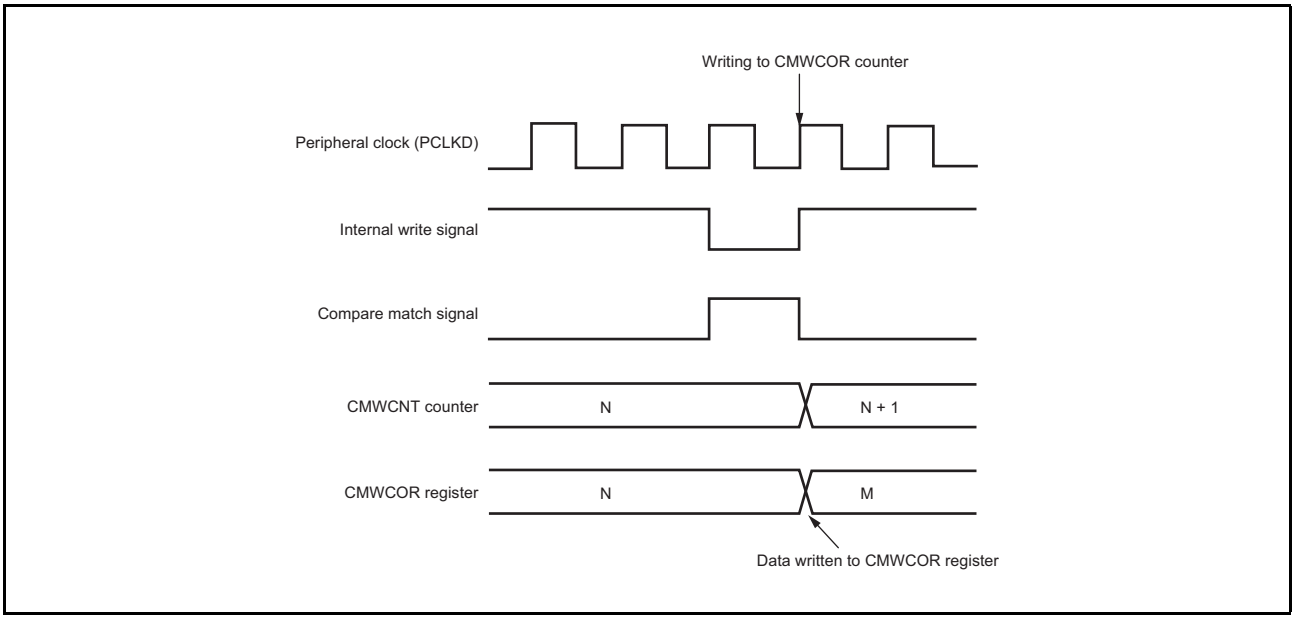

Figure 25.22 Contention between CMWCOR Register Writing and Compare Match

25.6.5 Contention between CMWOCR Register Writing and Compare Match

If the compare match is generated during CPU writing to the CMWOCR register, the CPU writing to the CMWOCR register proceeds and also the compare match signal is output.
Figure 25.23 shows the timing of contention between CMWOCR register writing and compare match.

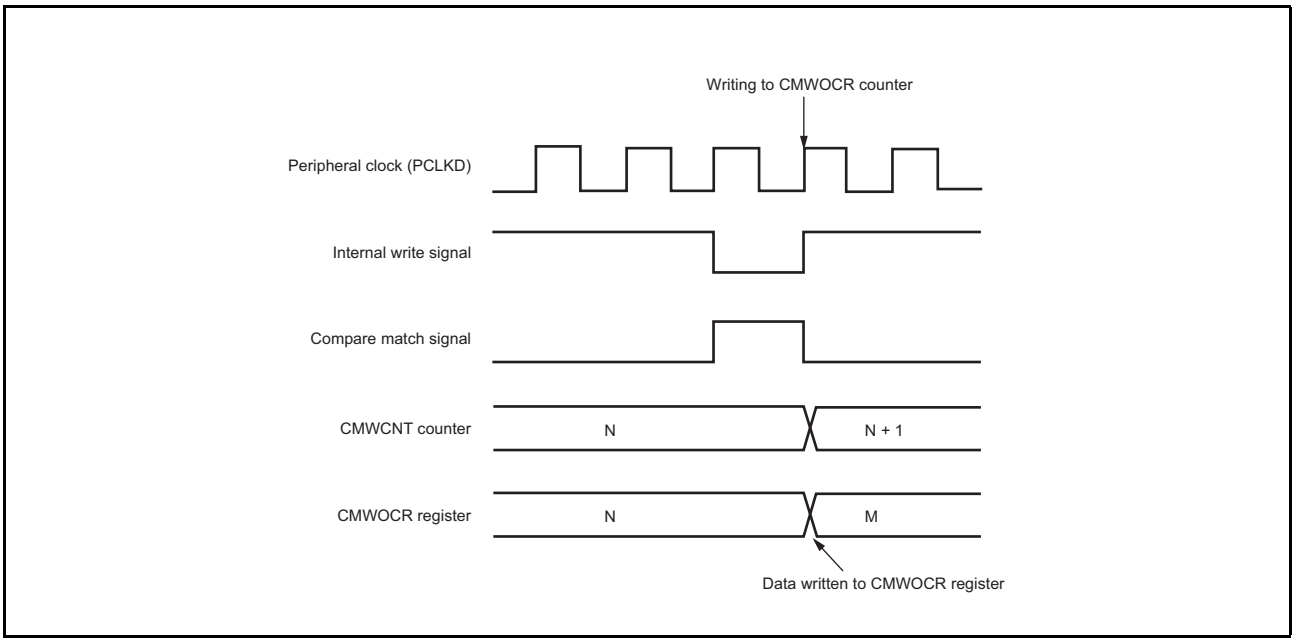

Figure 25.23 Contention between CMWOCR Register Writing and Compare Match

25.6.6 Contention between CMWCNT Counter Reading and Incrementing or Clearing

If the CMWCNT counter incrementing or clearing process occurs at the same time that the data of the CMWCNT counter is read, the value having been in the CMWCNT counter before incremented or cleared is read.
Figure 25.24 shows the timing of contention between the CMWCNT counter reading and incrementing.

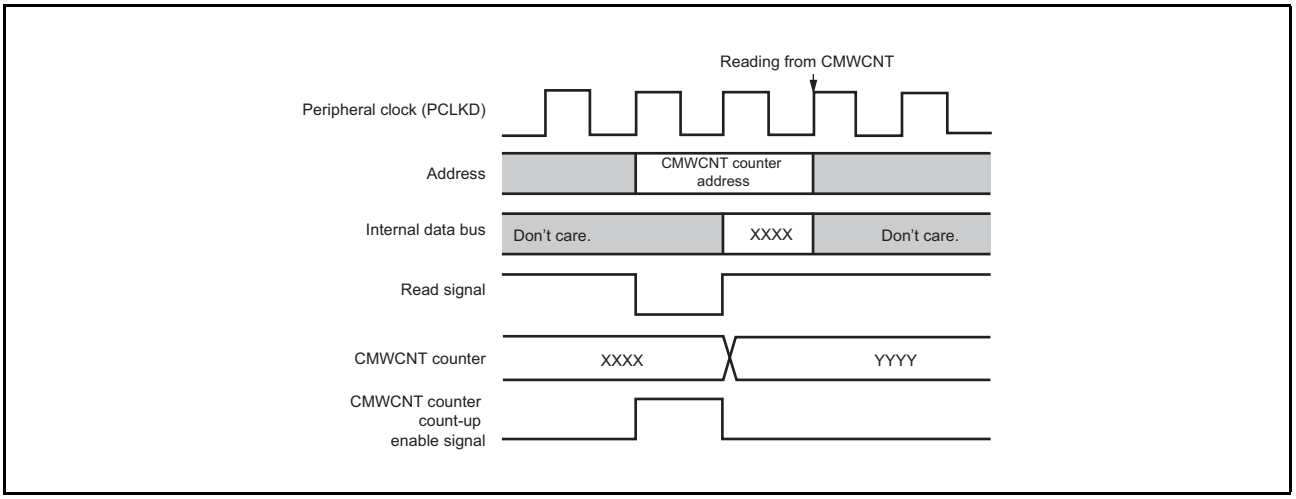

Figure 25.24 Contention between CMWCNT Counter Reading and Incrementing (When the Data Reading and Incrementing Process Occur Simultaneously)

25.6.7 Contention between CMWICR Register Reading and Input Capture

If the input capture signal is generated at the same time that the data of CMWICR register is read, the value having been in CMWICR register before updated by input capture transfer is read.

Figure 25.25 shows the timing of contention between CMWICR register reading and input capture.

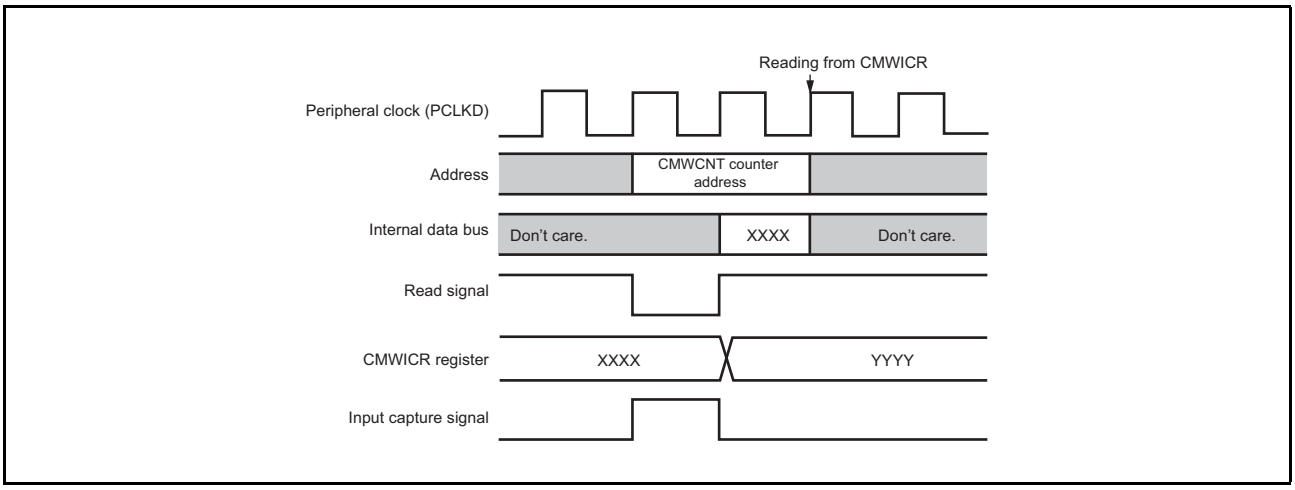

Figure 25.25 Contention between CMWICR Register Reading and Input Capture (When the Input Capture Signal and Read Signal are Generated Simultaneously)

25.6.8 Contention between Event Link Operation and Register Access

The followings are the notes on using CMTW for event link operations.
Table 25.4 summarizes contention between operations due to the event link, access to registers, and changes to the counter's state.

(1) Start Counting

When writing to the STR bit in the CMWSTR register and acceptance of the event signal are in contention, the CPU writing to the STR bit is ignored since setting of the STR bit to 1 in response to the event is given priority.

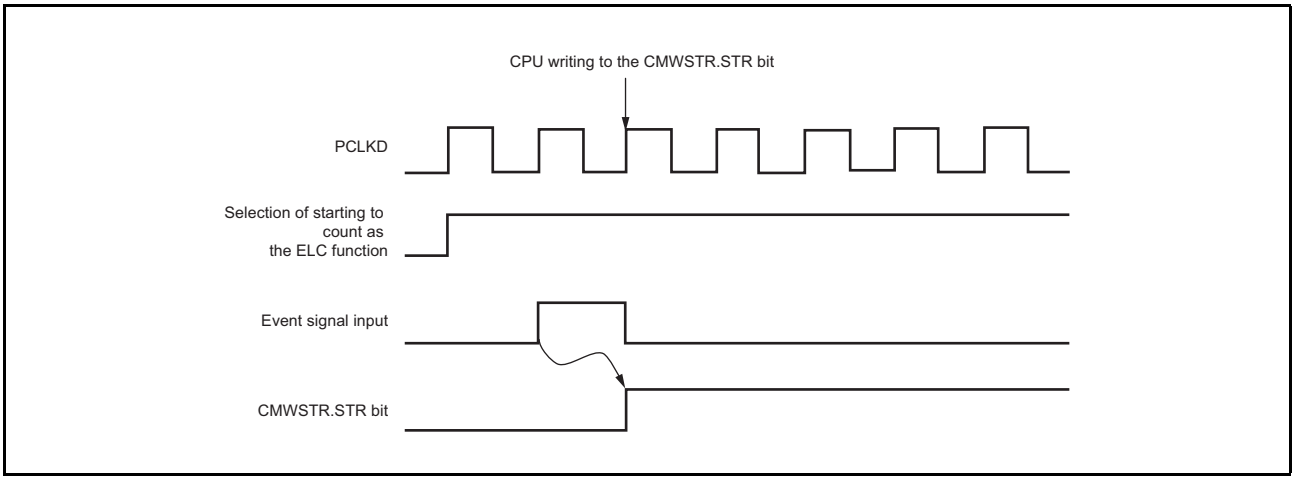

Figure 25.26 Contention between Event Acceptance and Register Access in Counting Start Operation

(2) Event Counting

When writing to CMWCNT (the timer counter) and acceptance of the event signal are in contention, the CPU writing to the CMWCNT counter is ignored since the counting operation in response to the event is given priority.

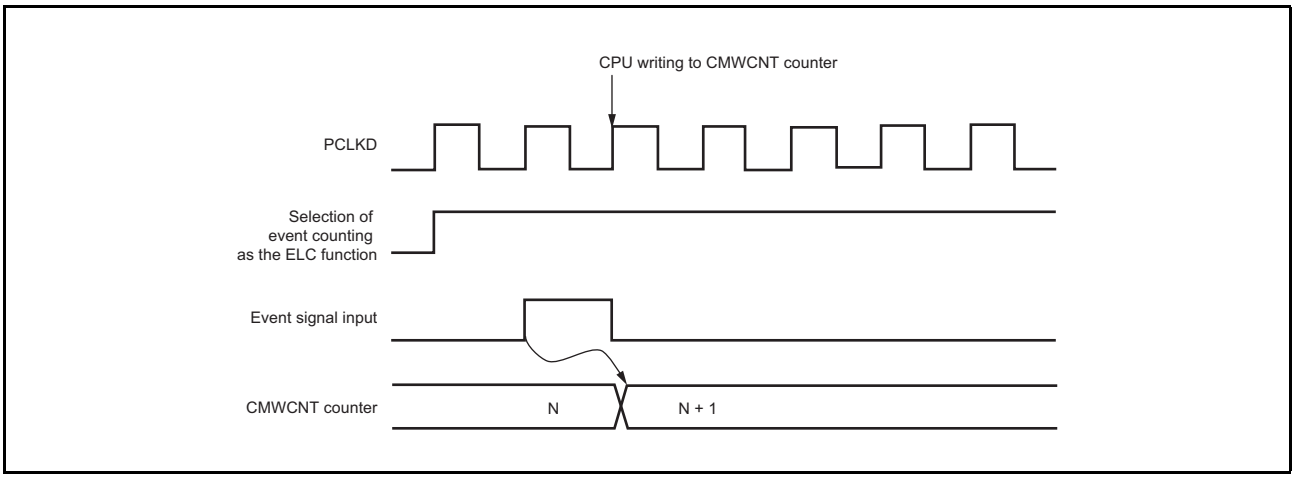

Figure 25.27 Contention between Event Acceptance and Register Access in Event Counting Operation

(3) Clear a Counter

When writing to CMWCNT (the timer counter) and acceptance of the event signal are in contention, the CPU writing to the CMWCNT counter is ignored since the counter value initialization in response to the event occurrence is given priority.

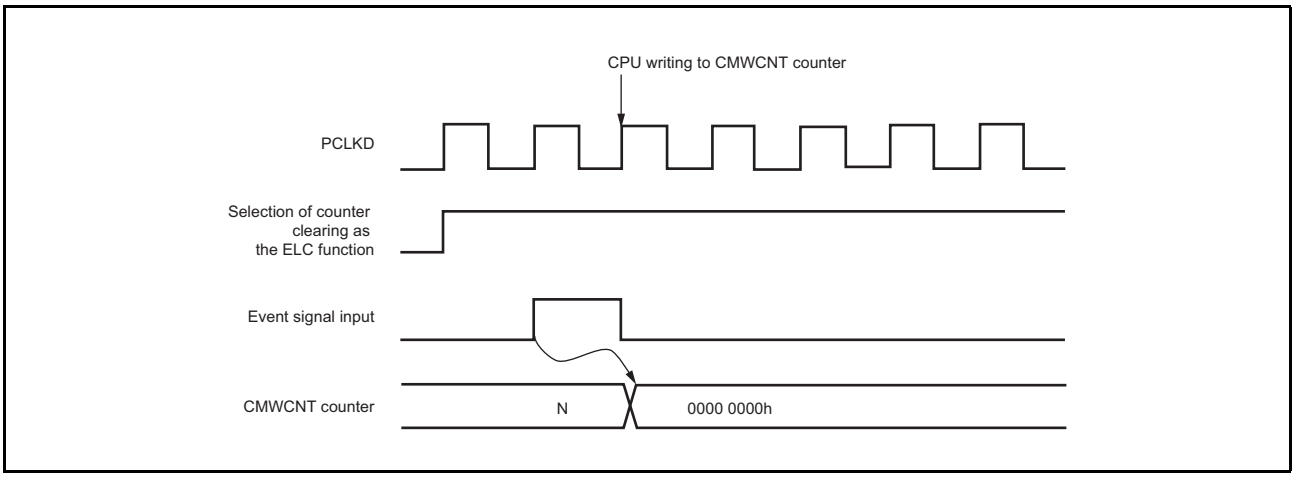

Figure 25.28 Contention between Event Acceptance and Register Access in Counting Clear Operation

Table 25.4 Summary of Contention between Operations Due to the Event Link, Access to Registers, and Changes to the Counter's State

Event Link Operation	Register Access	CMWCNT State	CMWICR0/1 State	Operation to be Performed
Counting start	Writing to CMWSTR.STR	Stopped state	—	Counting start
		Operating	—	Counting start
		Compare match	—	Counting start (CMWSTR.STR retains 1) and compare match
		Counting up	—	Counting start (CMWSTR.STR retains 1) and counting up
Event counting	Writing to CMWCNT	—	—	Event counting
	Writing to CMWCOR	Compare match	—	Compare match
Counting clear	Writing to CMWCNT	Other than compare match	—	Counting clear
	Writing to CMWCNT	Compare match	—	Compare match and counter clear
	(No access to registers)	Compare match	—	Compare match and counter clear
(No events)	Writing to CMWCNT	Compare match	—	Output of compare match interrupt request / Writing to CMWCNT
		Counting up	—	Writing to CMWCNT
	Writing to CMWCOR	Compare match	—	Compare match
	Writing to CMWOCR0	Output compare 0	—	Output compare 0
	Writing to CMWOCR1	Output compare 1	—	Output compare 1
	Reading from CMWCNT	Counting up	—	Counting up and reading of the previous value
	Reading from CMWICR0	—	Input capture 0	Input capture 0 and reading of the value before transfer
	Reading from CMWICR1	—	Input capture 1	Input capture 1 and reading of the value before transfer

26. Watchdog Timer (WDTA)

The watchdog timer (WDT) contains a 14-bit down-counter. If the counter underflows, an error notification to the error control module (ECM) is generated. The count value of the down-counter can be refreshed to the value after reset to enable counting to start again. Counter refreshing can be preformed during a period (the refresh-permitted period) you specify. If you perform refresh (register writing) outside of the permitted period, an error notification is generated and sent to the ECM. This enables detection of runaway of the program, taking the refresh interval into consideration. If underflow occurs or if refresh is performed outside of the refresh-permitted period, the WDT stops counting. Counting restarts after refresh is performed. (For details on refresh operation, see section 26.3.3, Refresh Operation.)
For details on the error control module (ECM), see section 42, Error Control Module (ECM).

26.1 Overview

WDT starts counting when refresh (register writing) is performed after reset is released.
Before starting the count, it is necessary to set the clock division ratio, the window start/end positions, and the timeout period in the WDT control register (WDTCR).
Table 26.1 lists the specifications of the WDT and Figure 26.1 shows a block diagram of the WDT.

Table 26.1 WDT Specifications

Item	Specifications
Number of internal channels	One channel (two channels for products incorporating an R-IN engine)
Count source	Peripheral clock (PCLKE)
Clock division ratio	Divide by 4, 64, 128, 512, 2048, or 8192
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	Refresh (writing 00h and then FFh to the WDTRR register)
Conditions for stopping the counter	• Reset (the down-counter and other registers return to the values after reset) • A counter underflows or a refresh error occurs
Window function	Window start and end positions can be specified (refresh-permitted period)
Sources of sending an error notification to ECM	• Down-counter underflows • Refreshing outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by the WDTSR register.
WDT register control	• Selection of clock division ratio after refresh operation (WDTCR.CKS[3:0] bits) • Selection of timeout period of the watchdog timer (WDTCR.TOPS[1:0] bits) • Selection of window start position of the watchdog timer (WDTCR.RPSS[1:0] bits) • Selection of window end position of the watchdog timer (WDTCR.RPES[1:0] bits)

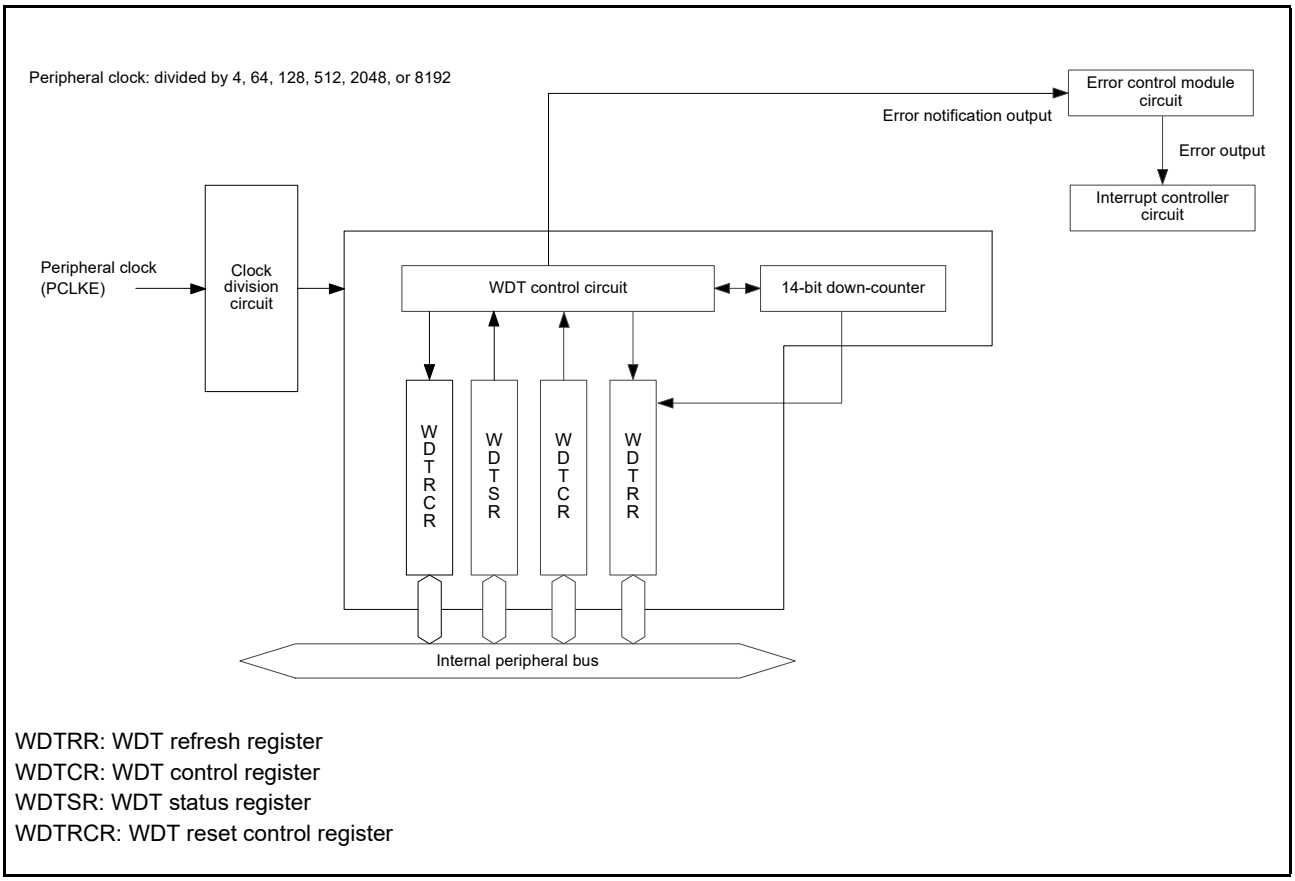

Figure 26.1 WDT Block Diagram

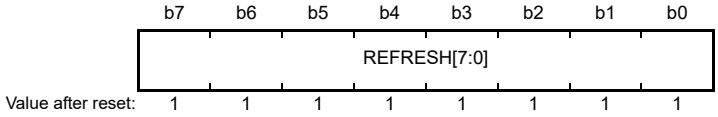
26.2 Register Descriptions

26.2.1 WDT Refresh Register (WDTRR)

The WDTRR register refreshes the down-counter of the WDT. To refresh the down-counter of the WDT, write 00h and then FFh (refresh operation) to the WDTRR register in the refresh-permitted period. After being refreshed, the down-counter starts counting down from the value specified with the WDTCR.TOPS[1:0] bits.
When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is always FFh.
For details on the refresh operation, see section 26.3.3, Refresh Operation.

Address(es): WDT0.WDTRR A008 0600h, WDT1.WDTRR A008 0620h



Note: For a reset by the WDT1, the values after a reset are the same as those on release from software reset 2. For details, see section 6, Reset.

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	REFRESH [7:0]	Refresh Register	The down-counter is refreshed by writing 00h and then writing FFh to this register.	R/W

26.2.2 WDT Control Register (WDTCR)

The WDTCR register allows you to select a timeout period before the down-counter underflows, a clock division ratio, and a window start/end position for refreshing. There are some restrictions on writing to this register. For details, see section 26.3.2, Control over Writing to the WDTCR and WDTRCR Registers.

Address(es): WDT0.WDTCR A008 0602h, WDT1.WDTCR A008 0622h

b11, b10	—	Reserved	These bits are read as 0 and cannot be modified.	R/W
b13, b12	RPSS[1:0]	Window Start Position Selection	These bits allow selection of a window start position of the down-counter from among 100%, 75%, 50%, and 25% of the counting period (assuming that the count start position as 100% and underflow occurrence as 0%). The period from the window start position to the window end position is the refresh-permitted period, and any other periods are the refresh-prohibited periods. Figure 26.2 shows the relation between the settings of the RPSS[1:0] and RPES[1:0] bits and the refresh-permitted and refresh-prohibited periods. b13 b12 0 0: 25% 0 1: 50% 1 0: 75% 1 1: 100% (window start position is not specified)	R/W
b15, b14	—	Reserved	These bits are read as 0 and cannot be modified.	R/W

TOPS[1:0] Bits (Timeout Period Selection)

These bits allow you to select a timeout period (period before the down-counter underflows) from among 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (the number of peripheral clock (PCLKE) cycles) before the counter underflows.

Table 26.2 lists relations between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of PCLKE cycles.

CKS[3:0] Bits (Clock Division Ratio Selection)

These bits allow you to select a division ratio from among the peripheral clocks (PCLKE) divided by 4, 64, 128, 512, 2048, and 8192. Combined with the TOPS[1:0] bit setting, a counting period between 4,096 and 134,217,728 cycles of the peripheral clock (PCLKE) can be selected for the WDT.

RPES[1:0] Bits (Window End Position Selection)

These bits allow selection of a window end position from among 75%, 50%, 25%, and 0% of the counting period. The selected window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is valid.

The counter values of the window start and end positions specified by the RPES[1:0] and RPSS[1:0] bit settings vary according to the TOPS[1:0] bit setting.

Table 26.3 lists the counter values of the window start and end positions corresponding to the TOPS[1:0] bit setting.

RPSS[1:0] Bits (Window Start Position Selection)

These bits allow selection of a window start position of the down-counter from among 100%, 75%, 50%, and 25% of the counting period (assuming that the count start position as 100% and underflow occurrence as 0%). The period from the window start position to the window end position is the refresh-permitted period, and any other periods are the refresh-prohibited periods.

Figure 26.2 shows the relation between the settings of the RPSS[1:0] and RPES[1:0] bits and the refresh-permitted and refresh-prohibited periods.

Table 26.2 Timeout Period Settings

CKS[3:0] Bits				TOPS[1:0] Bits				
b7	b6	b5	b4	b1	b0	Clock Division Ratio	Timeout Period (Number of Cycles)	No. of Peripheral Clock (PCLKE) Cycles @Count clock = PCLKE

		0	0		75

Note: If window end setting ≥ window start setting, the window end setting is set to 0%.

Figure 26.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted and Refresh-Prohibited Periods

26.2.3 WDT Status Register (WDTSR)

The WDTSR register shows the counter value of the down-counter and whether an underflow or refresh error has occurred.

Address(es): WDT0.WDTSR A008 0604h, WDT1.WDTSR A008 0624h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note: For a reset by the WDT1, the values after a reset are the same as those on release from software reset 2. For details, see section 6, Reset.

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	CNTVAL[13:0]	Down-Counter Value	Value counted by the down-counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred	R/(W)
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred	R/(W)

CNTVAL[13:0] Bits (Down-Counter Value)

Read these bits to confirm the value of the down-counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF Flag (Underflow Flag)

Read this bit to confirm whether an underflow has occurred in the down-counter.
The value 1 indicates that the down-counter has underflowed. The value 0 indicates that the down-counter has not underflowed.
Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

REFEF Flag (Refresh Error Flag)

Read this bit to confirm whether a refresh error (performing a refresh operation during a refresh-prohibited period) has occurred.
The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.
Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

26.2.4 WDT Reset Control Register (WDTRCR)

The WDTRCR register controls whether to send an error notification to the error control module (ECM) when underflow occurs in the down-counter of WDT.

There are some restrictions on writing to this register. For details, see section 26.3.2, Control over Writing to the WDTCR and WDTRCR Registers.

Address(es): WDT0.WDTRCR A008 0606h, WDT1.WDTRCR A008 0626h

	b7	b6	b5	b4	b3	b2	b1	b0
	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Note: For a reset by the WDT1, the values after a reset are the same as those on release from software reset 2. For details, see section 6, Reset.

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0 and cannot be modified.	R/W
b7	RSTIRQS	Reset Interrupt Request Selection	0: Error notification to ECM is permitted 1: Error notification to ECM is not performed	R/W

RSTIRQS Bit (Reset Interrupt Request Selection)

This bit specifies whether an error notification should be sent to the error control module (ECM) when an underflow or refresh error occurs in the down-counter.

26.3 Operation

26.3.1 Count Operation in Start Mode

Counting starts by a refresh operation of the WDT refresh register (WDTRR) when the WDT control register (WDTCR) and WDT reset control register (WDTRCR) are set.

26.3.1.1 Register Setting

After the reset state is released, set the clock division ratio, window start and end positions, and timeout period in the WDTCR register, and also set the error notification to the error control module (ECM) in the WDTRCR register. Then, the value specified by the WDTCR.TOPS[1:0] bits is set in the down-counter by a refresh operation to start counting down.
Thereafter, the value in the counter is re-set at each refresh operation and count-down continues if the program runs normally and the counter is refreshed in the refresh-permitted period. The WDT does not output an error notification to ECM as long as the count-down continues. However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter is refreshed outside of the refresh-permitted period, the WDT outputs an error notification to the ECM.

Figure 26.3 shows an example of operation under the following conditions.

- Reset interrupt request bit (RSTIRQS): 0b (Error notification to ECM is permitted.)
- Window start position selection bits (RPSS[1:0]): 10b (75%)
- Window end position selection bits (RPES[1:0]): 10b (25%)

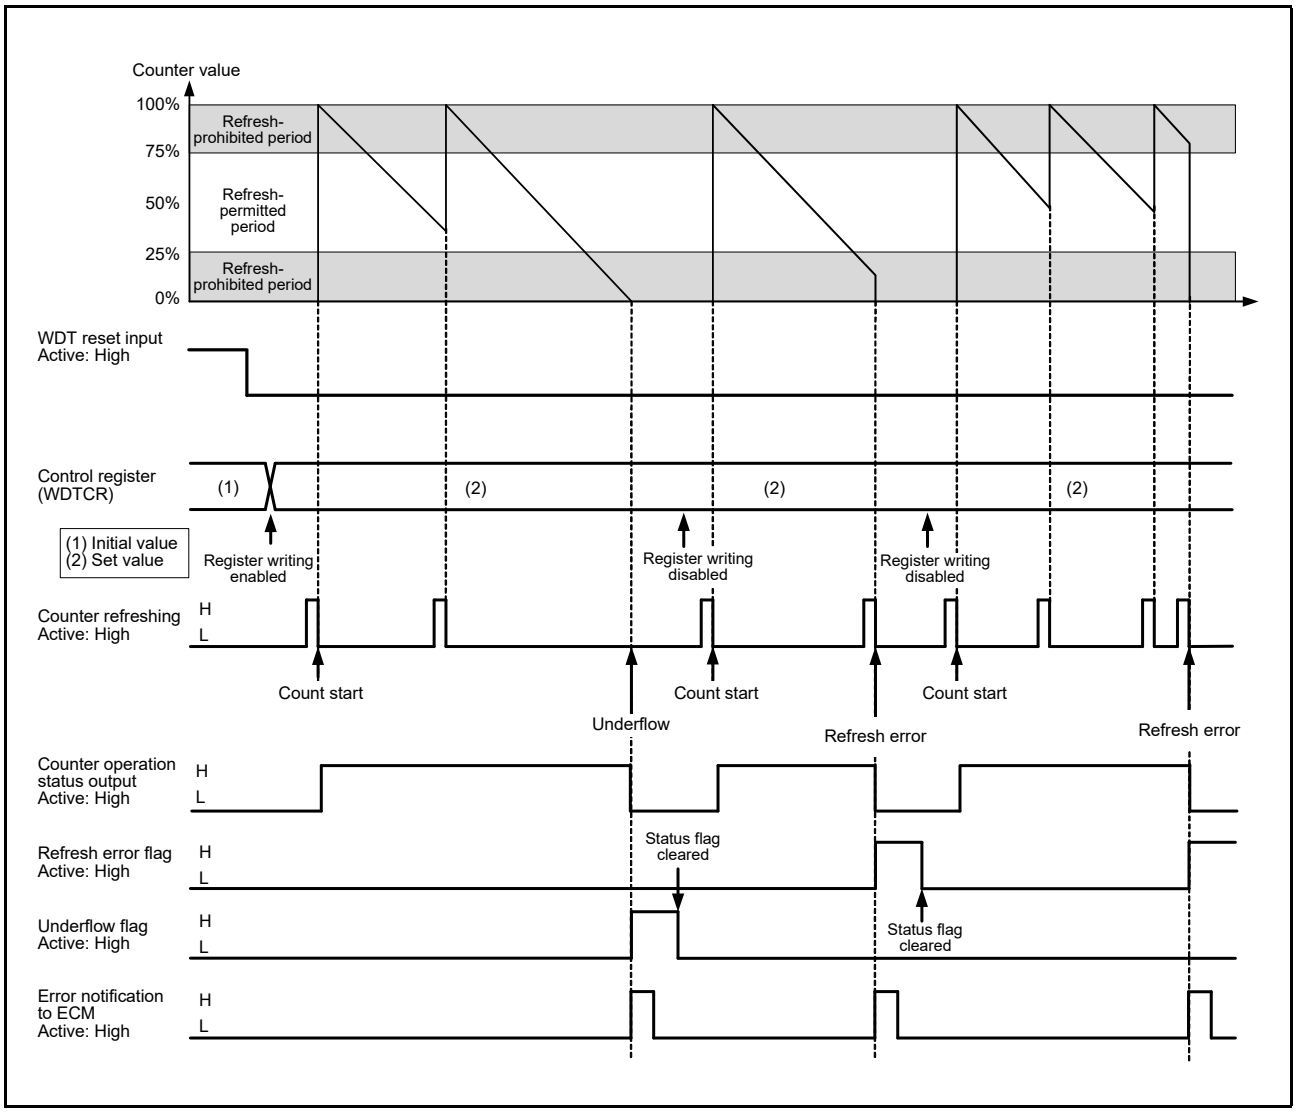

Figure 26.3 Operation Example in Register Start Mode

26.3.2 Control over Writing to the WDTCR and WDTRCR Registers

Writing to the WDT control register (WDTCR) is possible only once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or writing to the WDTCR register, the protection signal in the WDT becomes 1 and WDTCR is protected from subsequent attempts of writing.

Writing to the WDT reset control register (WDTRCR) is also controlled similarly.

This protection is released by the reset source for the WDT. Any other reset sources cannot release the protection.

Figure 26.4 shows control waveforms produced in response to writing to the WDTCR.

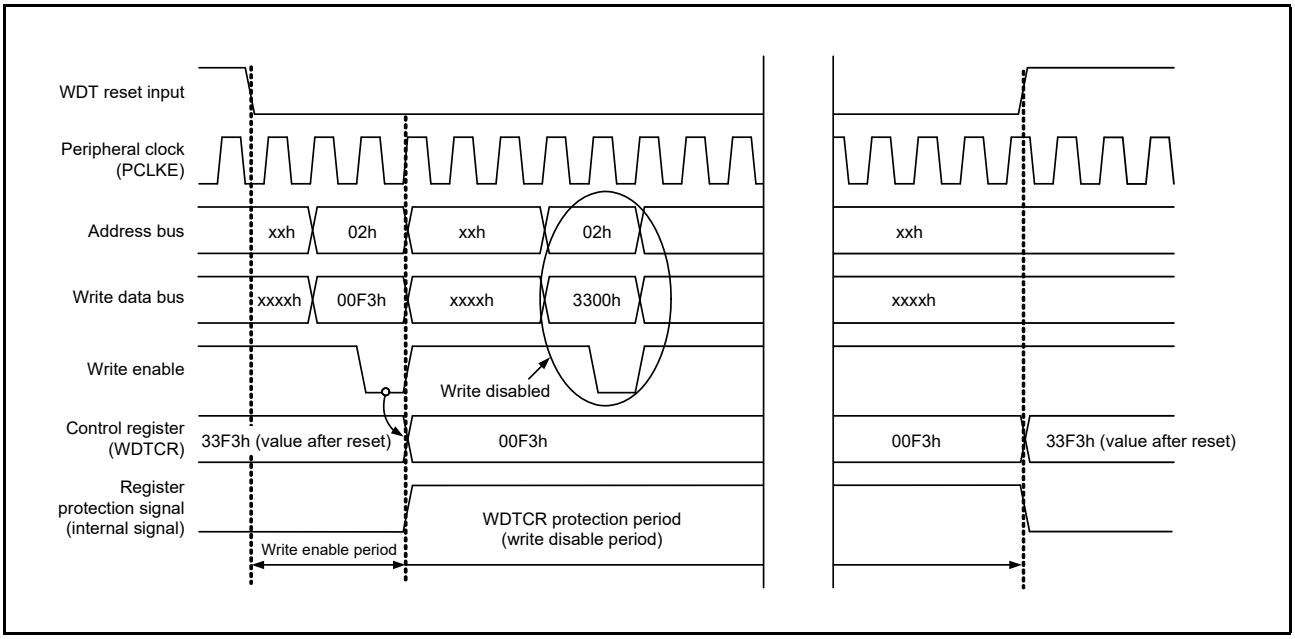

Figure 26.4 Control Waveforms Produced in Response to Writing to the WDTCR Register

26.3.3 Refresh Operation

To refresh the down-counter and to start the down-counter operation (count start due to refreshing), write the values 00h and then FFh to the WDT refresh register (WDTRR). If a value other than FFh is written after 00h, the down-counter is not refreshed. To perform refreshing after such invalid writing, write 00h and then FFh again to the WDTRR register.
If 00h is written twice in succession, writing FFh after the second 00h refreshes the down-counter because the 00h→FFh condition is satisfied. The writing sequence of 00h (n-1th)→00h (nth)→FFh also satisfies the refreshing condition and thus refreshes the down-counter.
Even if a register other than WDTRR is accessed or WDTRR is read between writing 00h and writing FFh to WDTRR, correct refreshing will be done.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h→FFh
- 00h (n–1-th time)→00h (nth time)→FFh
- 00h→access to another register or read from WDTRR→FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h)→FFh
- 00h→54h (a value other than FFh)
- 00h→AAh (values other than 00h and FFh)→FFh

If FFh is written to the WDTRR register during the refresh-permitted period after 00h is written outside of the period, write operation is acknowledged and down-counter is refreshed. (Whether writing is made within the refresh-permitted period is determined by when FFh is written.)

After FFh is written to the WDT refresh register (WDTRR), refreshing the down-counter requires up to four counting cycles. (The number of peripheral clock (PCLKE) cycles in a single counting cycle differs depending on the setting of the clock division ratio selection bits (WDTCR.CKS[3:0]).) Therefore, writing FFh to the WDTRR register should be completed within four count-cycles before the refresh-permitted period end position or before the down-counter underflows. Confirm the down-counter value with the down-counter value bits (WDTSR.CNTVAL[13:0]).

[Sample of refresh operation timing]

- When the window start position is 1FFFh, if 00h is written to the WDTRR register before 1FFFh (for example, 2002h), the down-counter can be refreshed by writing FFh to the WDTRR register after the value of WDTSR.CNTVAL[13:0] becomes 1FFFh.
- When the window end position is 1FFFh, if the value of WDTSR.CNTVAL[13:0] is 2003h (four counts before 1FFFh) or more immediately after 00h and FFh are written to the WDTRR register, the down-counter will be refreshed.
- If the refresh-permitted period ranges down to 0000h, refreshing is possible until just before underflow. In this case, if the value of WDTSR.CNTVAL[13:0] is 0003h (four counts before underflow) or more immediately after 00h and FFh are written to the WDTRR register, underflow does not occur and the down-counter is refreshed.

Figure 26.5 shows the WDT refresh-operation waveforms when the clock division ratio = PCLKE/64.

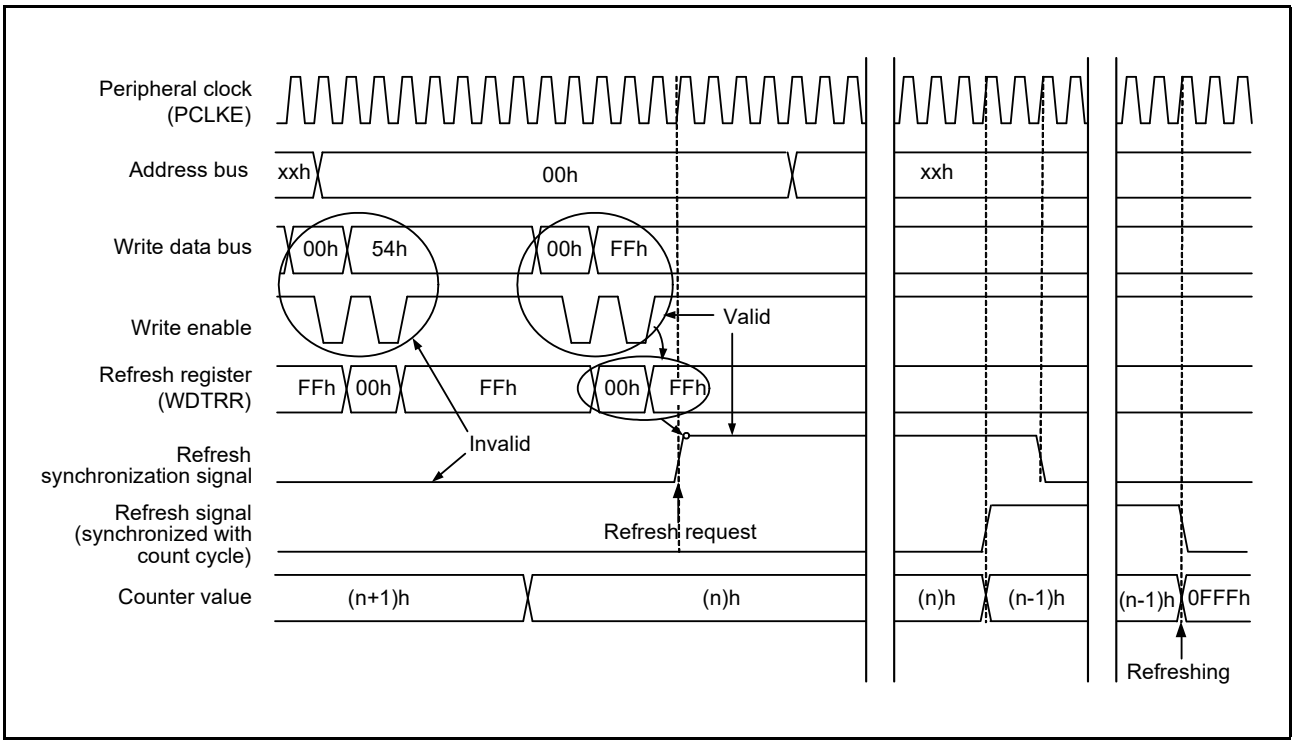

Figure 26.5 WDT Refresh Operation Waveforms (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

26.3.4 Status Flag

The refresh error flag (WDTSR.REFEF) and the underflow flag (WDTSR.UNDFF) retain the error causes after error notifications were output to the error control module (ECM) of WDT.
Occurrence state of error notifications to ECM can be confirmed by reading the WDTSR.REFEF flag or the WDTSR.UNDFF flag after reset is released or upon occurrence of an error notification to ECM.
To clear these flags, write 0. Writing 1 is ignored.
If these flags are not cleared, it will give no effect to the operation. Upon occurrence of the next error notification to ECM, the previous error notification is automatically cleared and a new notification to ECM is written.

26.3.5 Error Notification to the Error Control Module (ECM)

When the reset interrupt selection bit (WDTRCR.RSTIRQS) is set to 0, underflow or refresh error of the down-counter causes an error notification to ECM to be generated during one count cycle.

26.3.6 Reading the Down-Counter Value

The WDT stores the counter value in the down-counter value bits (WDTSR.CNTVAL[13:0]) of the WDT status register. Thus, the counter value can be checked through the WDTSR.CNTVAL[13:0] bits.

Reading requires up to four peripheral clock (PCLKE) cycles. Therefore, the read value may differ from the actual down-counter value by one count.

Figure 26.6 shows the processing for reading the WDT down-counter value when the clock division ratio = PCLKE/64.

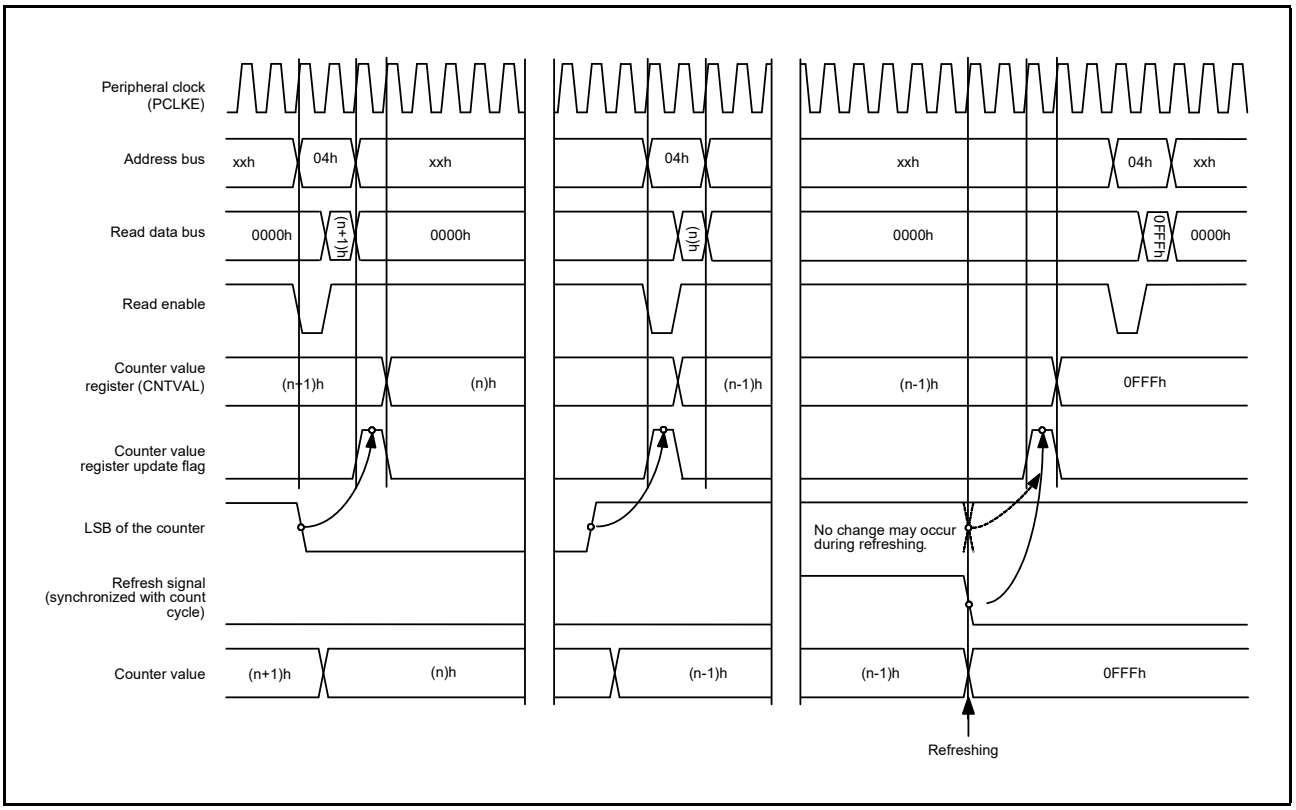

Figure 26.6 Processing for Reading WDT Down-Counter Value (WDTCR.CKS[3:0] = 0100b, WDTCR.TOPS[1:0] = 01b)

26.4 Low-Power Consumption Control

26.4.1 Watchdog Timer Operations in Low-Power Consumption Mode Transition

Clock supply can be controlled during transition to the standby mode of Cortex-R4 or the sleep mode of Cortex-M3 while the down-counter of WDT is operating.

Table 26.4 lists the WDT operations during transition to the low-power consumption mode.

Table 26.4 WDT Operations during Transition to Low-Power Consumption Mode <in Low-Power Consumption Mode Transition>

Low-Power Consumption Mode	WDT0 Clock Supply	WDT1 Clock Supply	WDT0 Operation	WDT1 Operation
Cortex-R4 standby	√	√	√	√
Cortex-M3 sleep	√	√	√	√

√: Operating

27. Independent Watchdog Timer (IWDTa)

The independent watchdog timer (IWDT) contains a 14-bit down-counter. If the counter underflows, an error notification to the error control module (ECM) is generated. The count value of the down-counter can be refreshed to the value after reset to enable counting to start again. Counter refreshing can be preformed during a period (the refresh-permitted period) you specify. If you perform refresh (register writing) outside of the permitted period, an error notification is generated and sent to the ECM. This enables detection of runaway of the program, taking the refresh interval into consideration. If underflow occurs or if refresh is performed outside of the refresh-permitted period, the IWDT stops counting. Counting restarts after refresh is performed. (For details on refresh operation, see section 27.3.3, Refresh Operation.)
For details on the error control module (ECM), see section 42, Error Control Module (ECM).

27.1 Overview

The IWDT starts counting when refresh (register writing) is performed after reset is released.
Before starting the count, it is necessary to set the clock division ratio, the window start/end positions, and the timeout period in the IWDT control register (IWDTCR).
Table 27.1 lists the specifications of the IWDT.

Table 27.1 IWDT Specifications

Item	Description
Count source	IWDT clock (IWDTCLK)
Clock division ratio	Division by 1, 16, 32, 64, 128, or 256
IWDT clock (IWDTCLK) oscillation enable	IWDT clock oscillation starts by a refresh operation.
Counter operation	Counting down using a 14-bit down-counter
Conditions for starting the counter	Counting starts by refreshing the counter (writing 00h and then FFh to the IWDTRR register).
Conditions for stopping the counter	• Reset (the down-counter and other registers return to the values after reset) • A counter underflows or a refresh error is generated
Window function	Window start and end positions can be specified (refresh-permitted period)
Sources for the output of error notification to ECM	• When the down-counter underflows • When refreshing is done outside the refresh-permitted period (refresh error)
Reading the counter value	The down-counter value can be read by reading the IWDTSR register.
IWDT register control	• Selecting the clock frequency division ratio after refreshing (IWDTCR.CKS[3:0] bits) • Selecting the timeout period of the independent watchdog timer (IWDTCR.TOPS[1:0] bits) • Selecting the window start position in the independent watchdog timer (IWDTCR.RPSS[1:0] bits) • Selecting the window end position in the independent watchdog timer (IWDTCR.RPES[1:0] bits)

For operation to continue even if the peripheral clock (PCLKB) stops unexpectedly, counting by the IWDT is driven by two clock signals, the peripheral clock (PCLKB) and the IWDT clock (IWDTCLK). The peripheral clock (PCLKB) provides the timing for the bus interface and registers, and the IWDT clock (IWDTCLK) provides the timing for the 14-bit down-counter and control circuits.
Signals between the peripheral clock (PCLKB) operation blocks and the IWDT clock (IWDTCLK) operation blocks are connected via a synchronization circuit.

Figure 27.1 is a block diagram of the IWDT.

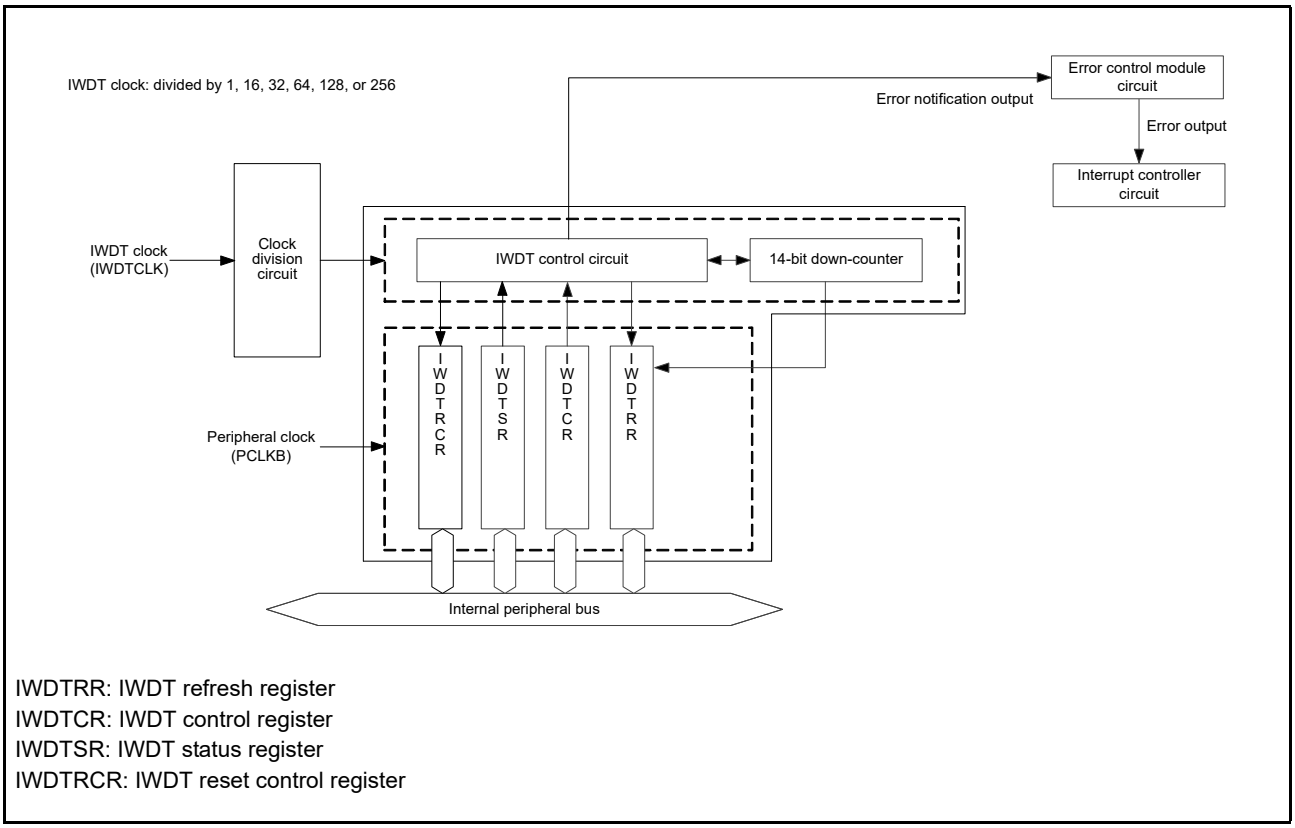

Figure 27.1 IWDT Block Diagram

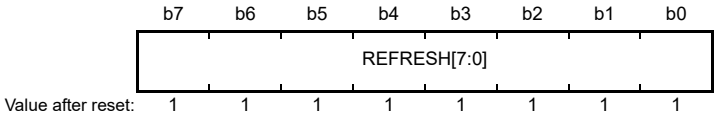
27.2 Register Descriptions

27.2.1 IWDT Refresh Register (IWDTRR)

The IWDTRR register refreshes the down-counter of the IWDT.
To refresh the down-counter of the IWDT, write 00h and then FFh (refresh operation) to the IWDTRR register in the refresh-permitted period. After being refreshed, the down-counter starts counting down from the value specified with the IWDTCR.TOPS[1:0] bits.
When 00h is written, the read value is 00h. When a value other than 00h is written, the read value is always FFh. For details on the refresh operation, see section 27.3.3, Refresh Operation.

Address(es): A008 0700h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	REFRESH [7:0]	Refresh Register	The down-counter is refreshed by writing 00h and then writing FFh to this register.	R/W

27.2.2 IWDT Control Register (IWDTCR)

The IWDTCR register allows you to select a timeout period before the down-counter underflows, a clock division ratio, and a window start/end position for refreshing.

There are some restrictions on writing to this register. For details, see section 27.3.2, Control Over Writing to the IWDTCR and IWDTRCR Registers.

TOPS[1:0] Bits (Timeout Period Selection)

These bits allow you to select a timeout period (a period before the down-counter underflows) from among 1024, 4096, 8192, and 16384 cycles, taking the divided clock specified by the CKS[3:0] bits as one cycle. After the down-counter is refreshed, the combination of the CKS[3:0] and TOPS[1:0] bits determines the time (the number of IWDT clock (IWDTCLK) cycles) before the counter underflows.

Table 27.2 lists relations between the CKS[3:0] and TOPS[1:0] bit settings, the timeout period, and the number of IWDT clock (IWDTCLK) cycles.

CKS[3:0] Bits (Clock Division Ratio Selection)

These bits allow you to select the IWDT clock (IWDTCLK) division ratio from among division by 1, 16, 32, 64, 128, and 256. Combined with the TOPS[1:0] bit setting, a counting period between 1024 and 4194304 cycles of the IWDT clock (IWDTCLK) can be selected for the IWDT. The down-counter value may not be read correctly depending on the relation between the lowest peripheral clock (PCLKB) frequency and the highest IWDT clock (IWDTCLK) frequency.

RPES[1:0] Bits (Window End Position Selection)

These bits allow selection of a window end position from among 75%, 50%, 25%, and 0% of the counting period. The selected window end position should be a value smaller than the window start position (window start position > window end position). If the window end position is greater than the window start position, only the window start position setting is valid.

The counter values of the window start and end positions specified by the RPES[1:0] and RPSS[1:0] bit settings vary according to the TOPS[1:0] bit setting.

Table 27.3 lists the counter values of the window start and end positions corresponding to the TOPS[1:0] bit setting.

RPSS[1:0] Bits (Window Start Position Selection)

These bits allow selection of a window start position of the down-counter from among 100%, 75%, 50%, and 25% of the counting period (assuming that the count start position as 100% and underflow occurrence as 0%). The period from the window start position to the window end position is the refresh-permitted period, and any other periods are the refresh-prohibited periods.

Figure 27.2 shows the relation between the settings of the RPSS[1:0] and RPES[1:0] bits and the refresh-permitted and refresh-prohibited periods.

Table 27.2 Settings and Timeout Periods

Note: If window end setting ≥ window start setting, the window end setting is set to 0%.

Figure 27.2 RPSS[1:0] and RPES[1:0] Bit Settings and the Refresh-Permitted Period

27.2.3 IWDT Status Register (IWDTSR)

The IWDTSR register shows the counter value of the down-counter and whether an underflow or refresh error has occurred.

Address(es): A008 0704h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REFEF	UNDFF	CNTVAL[13:0]													
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	CNTVAL[13:0]	Counter Value	Value counted by the counter	R
b14	UNDFF	Underflow Flag	0: No underflow occurred 1: Underflow occurred	R/(W)
b15	REFEF	Refresh Error Flag	0: No refresh error occurred 1: Refresh error occurred	R/(W)

CNTVAL[13:0] Bits (Counter Value)

Read these bits to confirm the value of the down-counter, but note that the read value may differ from the actual count by a value of one count.

UNDFF Flag (Underflow Flag)

Read this bit to confirm whether an underflow has occurred in the down-counter.

The value 1 indicates that the down-counter has underflowed. The value 0 indicates that the down-counter has not underflowed.

Write 0 to the UNDFF flag to set the value to 0. Writing 1 has no effect.

REFEF Flag (Refresh Error Flag)

Read this bit to confirm whether a refresh error (performing a refresh operation during a refresh-prohibited period) has occurred.

The value 1 indicates that a refresh error has occurred. The value 0 indicates that no refresh error has occurred.

Write 0 to the REFEF flag to set the value to 0. Writing 1 has no effect.

27.2.4 IWDT Reset Control Register (IWDTRCR)

The IWDTRCR register controls whether to send an error notification to the error control module (ECM) when underflow occurs in the down-counter of IWDT.

There are some restrictions on writing to this register. For details, see section 27.3.2, Control Over Writing to the IWDTCR and IWDTRCR Registers.

Address(es): A008 0706h

	b7	b6	b5	b4	b3	b2	b1	b0
	RSTIRQS	—	—	—	—	—	—	—
Value after reset:	1	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	—	Reserved	These bits are read as 0. Writing to these bits has no effect.	R/W
b7	RSTIRQS	Reset Interrupt Request Selection	0: Error notification to ECM is permitted. 1: Error notification to ECM is not performed.	R/W

RSTIRQS Bit (Reset Interrupt Request Selection)

This bit specifies whether an error notification should be sent to the error control module (ECM) when an underflow or refresh error occurs in the down-counter.

27.3 Operation

27.3.1 Count Operation in Start Mode

Counting starts by a refresh operation of the IWDT refresh register (IWDTRR) if the IWDT control register (IWDTCR) and IWDT reset control register (IWDTRCR) are set.

27.3.1.1 Register Setting

After the reset state is released, set the clock division ratio, window start and end positions, and timeout period in the IWDTCR register, and also set whether to send an error notification to the error control module (ECM) in the IWDTRCR register. Then, the value specified by the timeout period selection bits (IWDTCR.TOPS[1:0]) is set in the down-counter by a refresh operation to start counting down.
Thereafter, the value in the counter is re-set at each refresh operation and count-down continues if the program runs normally and the counter is refreshed in the refresh-permitted period. The IWDT does not output an error notification to ECM as long as the count-down continues.
However, if the down-counter underflows because the down-counter cannot be refreshed due to a program runaway, or if a refresh error occurs because the counter is refreshed outside of the refresh-permitted period, the IWDT outputs an error notification to the ECM.

Figure 27.3 shows an example of operation under the following conditions.

- Reset interrupt request bit (IWDTCR.RSTIRQS): 0b (Error notification to ECM is permitted.)
- Window start position selection bits (IWDTCR.RPSS[1:0]): 10b (75%)
- Window end position selection bits (IWDTCR.RPES[1:0]): 10b (25%)

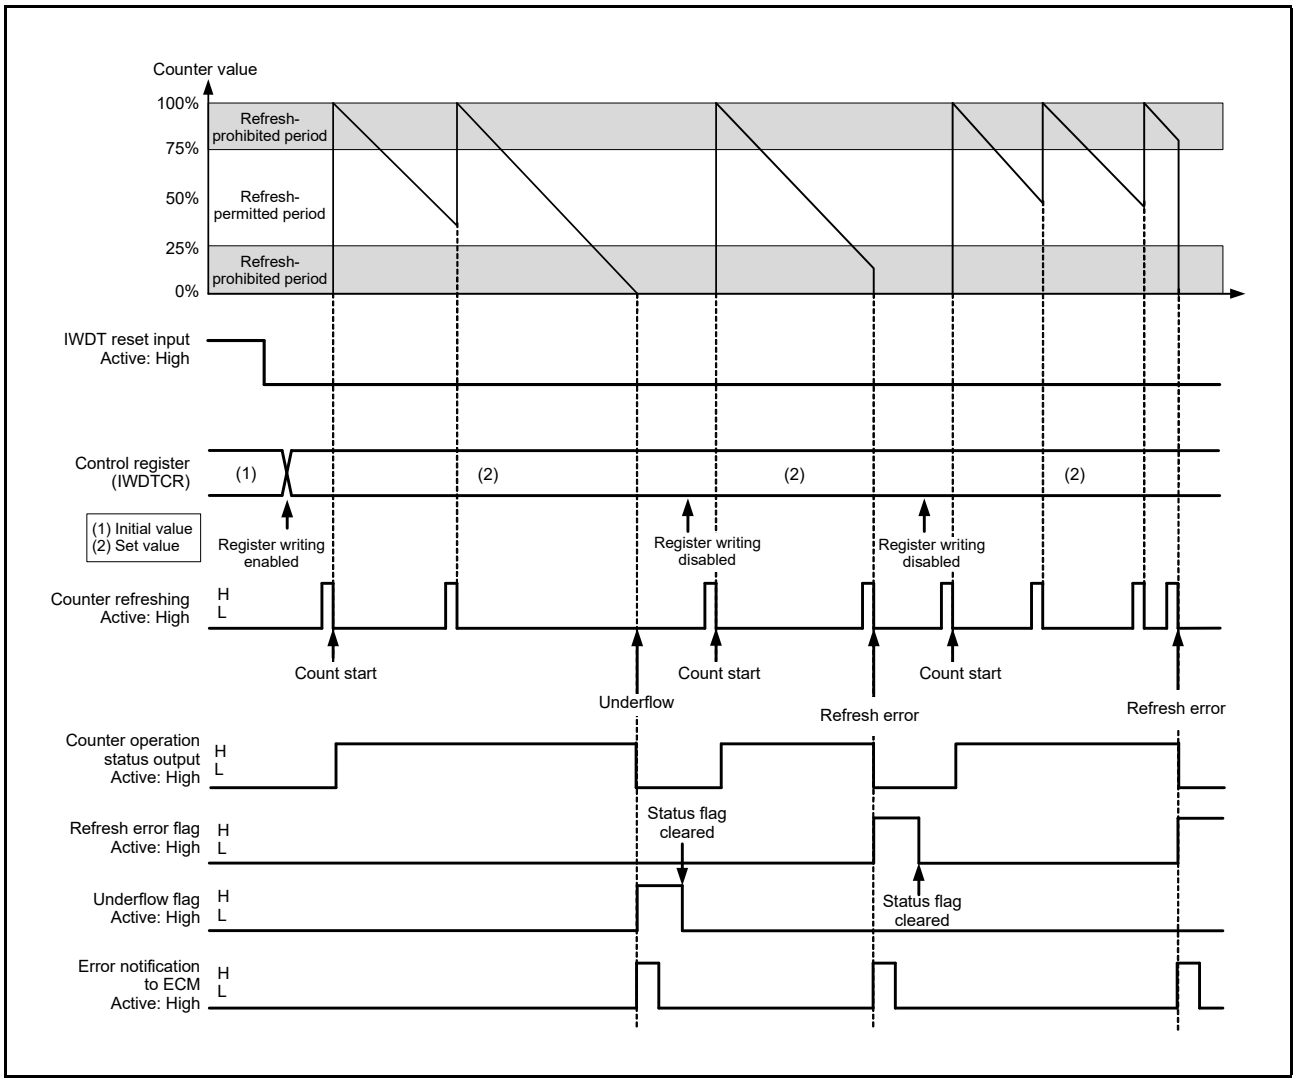

Figure 27.3 Operation Example in Register Start Mode

27.3.2 Control Over Writing to the IWDTCR and IWDTRCR Registers

Writing to the IWDT control register (IWDTCR) is possible only once between the release from the reset state and the first refresh operation.

After a refresh operation (counting starts) or writing to the IWDTCR register, the protection signal in the IWDT becomes 1 to protect IWDTCR from subsequent attempts of writing.

Writing to the IWDT reset control register (IWDTRCR) is also controlled similarly.

This protection is released by the reset source for the IWDT. With other reset sources, the protection is not released.

Figure 27.4 shows control waveforms produced in response to writing to the IWDTCR register.

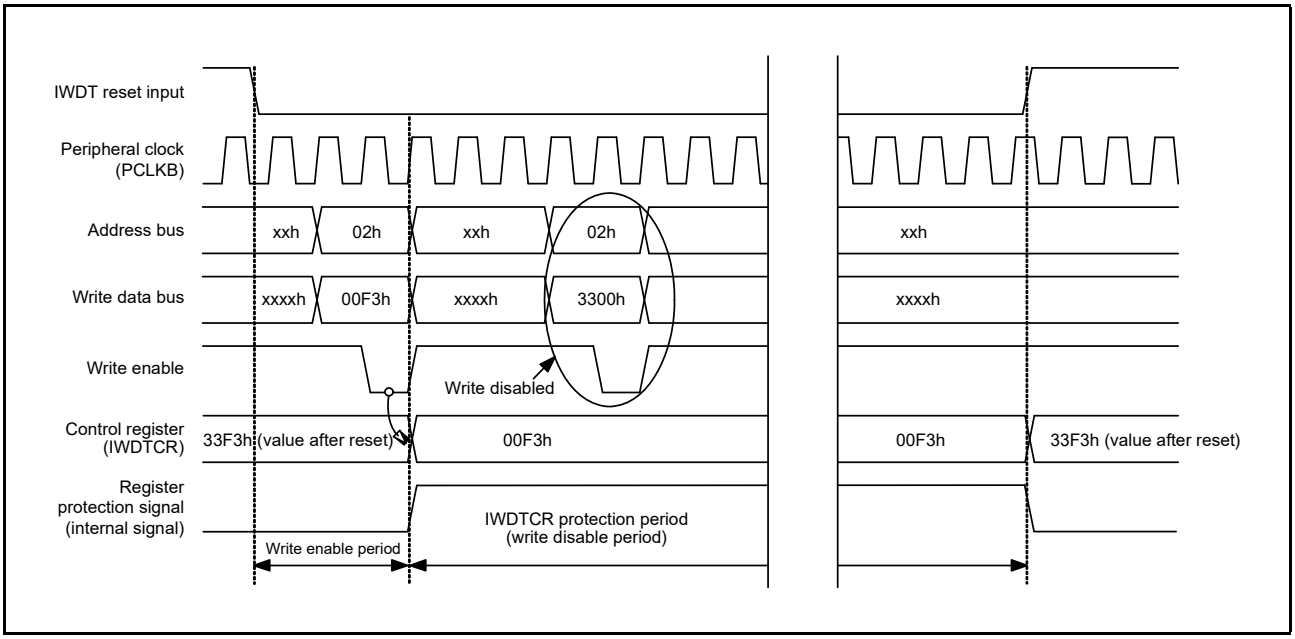

Figure 27.4 Control Waveforms Produced in Response to Writing to the IWDTCR Register

27.3.3 Refresh Operation

To refresh the counter and to start the counter operation (counting is started by refreshing), write the values 00h and then FFh to the IWDT refresh register (IWDTRR). If a value other than FFh is written after 00h, the counter is not refreshed. To perform refreshing after such invalid writing, write 00h and FFh again to the IWDT refresh register (IWDTRR).
When writing is done in the order of 00h (first time) → 00h (second time), and if FFh is written after that, the writing order 00h → FFh is satisfied; writing 00h (n–1-th time) → 00h (nth time) → FFh is valid and correct refreshing will be done. Moreover, even if a register other than IWDTRR is accessed or IWDTRR is read between writing 00h and writing FFh to IWDTRR, correct refreshing will be done.

[Sample sequences of writing that are valid for refreshing the counter]

- 00h → FFh
- 00h (n–1-th time) → 00h (nth time) → FFh
- 00h → access to another register or read from IWDTRR → FFh

[Sample sequences of writing that are not valid for refreshing the counter]

- 23h (a value other than 00h) → FFh
- 00h → 54h (a value other than FFh)
- 00h → AAh (values other than 00h and FFh) → FFh

Even when 00h is written to IWDTRR outside the refresh-permitted period, if FFh is written to IWDTRR in the refresh-permitted period, the writing sequence is valid and refreshing will be done. (Whether writing is made within the refresh-permitted period is determined by when FFh is written.)
After FFh is written to the IWDTRR register, refreshing the counter requires up to four cycles of the signal for counting (the clock division ratio selection bits (IWDTCR.CKS[3:0]) determine how many cycles of the IWDT clock (IWDTCLK) make up one cycle for counting). Therefore, writing FFh to the IWDTRR should be completed four-count cycles before the end position of the refresh-permitted period or a counter underflow. The value of the down-counter can be checked by the down-counter bits (IWDTSR.CNTVAL[13:0]).

[Sample refreshing timings]

- When the window start position is set to 1FFFh, even if 00h is written to IWDTRR before 1FFFh is reached (2002h, for example), refreshing is done if FFh is written to IWDTRR after the value of the IWDTSR.CNTVAL[13:0] bits has reached 1FFFh.
- When the window end position is set to 1FFFh, refreshing is done if 2003h (four-count cycles before 1FFFh) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to IWDTRR.
- When the refresh-permitted period continues until count 0000h, refreshing can be done immediately before an underflow. In this case, if 0003h (four-count cycles before an underflow) or a greater value is read from the IWDTSR.CNTVAL[13:0] bits immediately after writing 00h → FFh to IWDTRR, no underflow occurs and refreshing is done.

Figure 27.5 shows the IWDT refresh-operation waveforms when PCLKB > IWDTCLK and clock division ratio = IWDTCLK. Figure 27.6 shows the IWDT refresh-operation waveforms when PCLKB < IWDTCLK and clock division ratio = IWDTCLK/16.

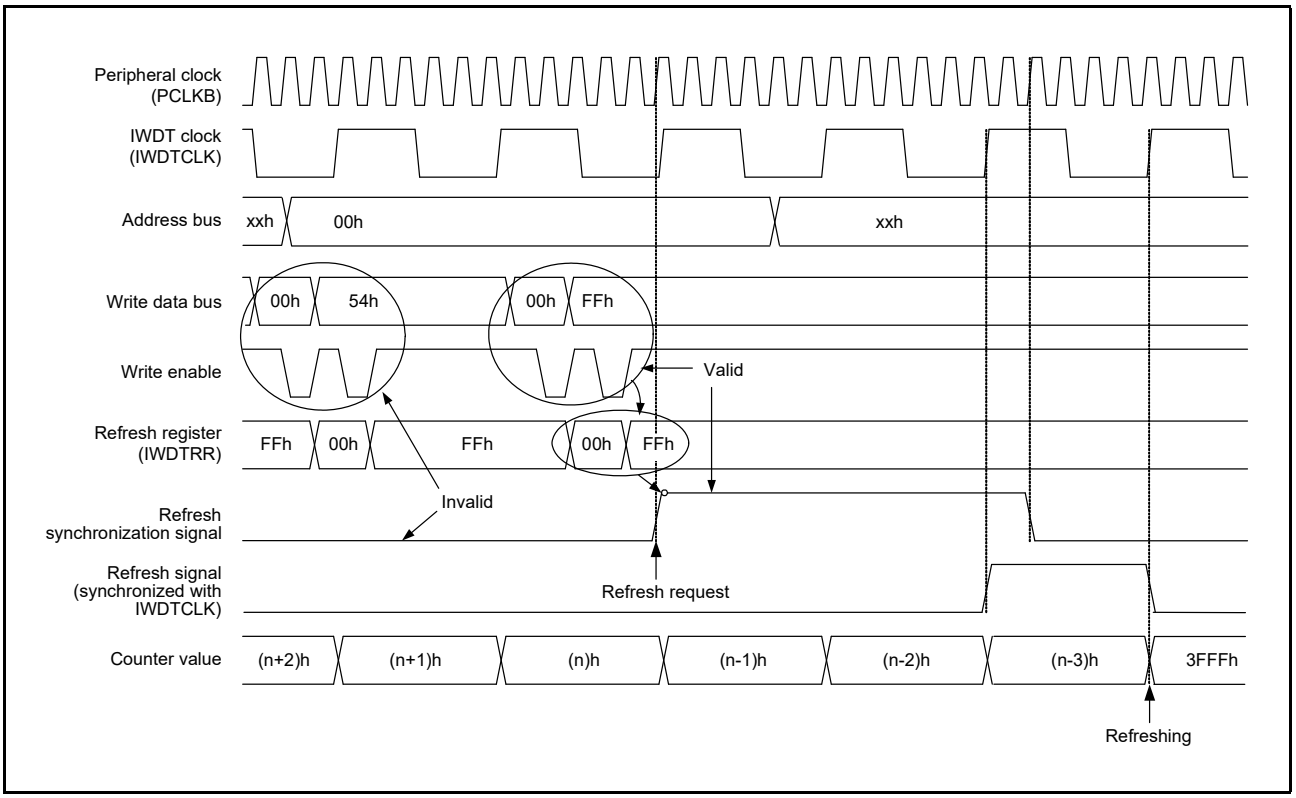

Figure 27.5 IWDT Refresh Operation Waveforms (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

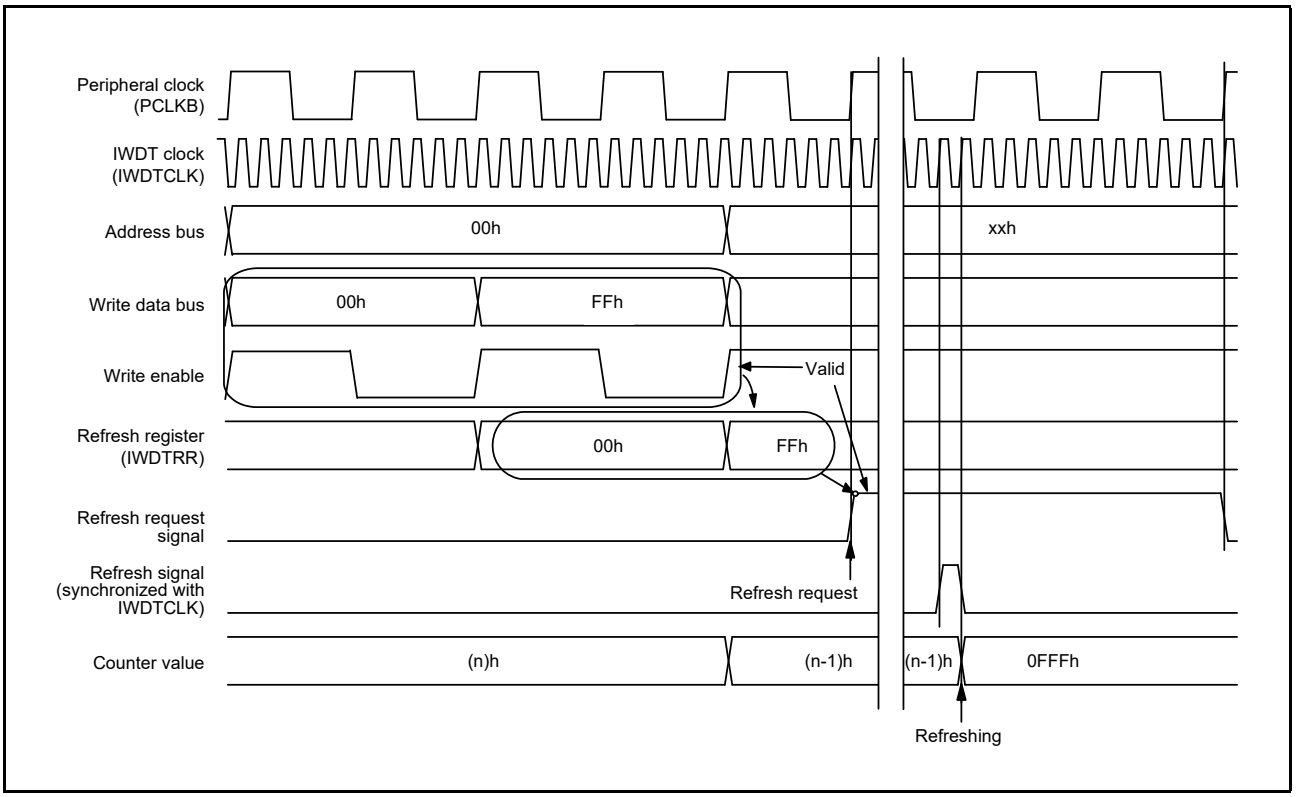

Figure 27.6 IWDT Refresh Operation Waveforms (IWDTCR.CKS[3:0] = 0010b, IWDTCR.TOPS[1:0] = 01b)

27.3.4 Status Flags

The refresh error flag (IWDTSR.REFEF) and the underflow flag (IWDTSR.UNDFF) retain the error causes when error notifications are output to the error control module (ECM) of IWDT.
Occurrence state of error notifications to ECM can be confirmed by reading the IWDTSR.REFEF flag or the IWDTSR.UNDFF flag after reset is released or upon occurrence of an error notification to ECM.
To clear these flags to 0, write 0. Writing 1 is ignored.
If these flags are not cleared, it will give no effect to the operation. Upon occurrence of the next error notification to ECM, the previous error notification is automatically cleared and a new notification to ECM is written.

27.3.5 Error Notification to the Error Control Module (ECM)

When the reset interrupt selection bit (IWDTRCR.RSTIRQS) is set to 0, underflow or refresh error of the down-counter causes an error notification to ECM to be generated during one count cycle.

27.3.6 Reading the Down-Counter Value

As the counter in the IWDT operates with the IWDT clock (IWDTCLK), the IWDT cannot read the counter value directly. Therefore, the IWDT synchronizes the counter value with the peripheral clock (PCLKB) and stores it in the counter value bits (IWDTSR.CNTVAL[13:0]) of the IWDT status register. Thus, the counter value can be checked indirectly through the IWDTSR.CNTVAL[13:0] bits.

Reading the counter value requires multiple PCLKB clock cycles (up to four clock cycles), and the read counter value may differ from the actual counter value by a value of one count.

Figure 27.7 shows the processing for reading the IWDT down-counter value.

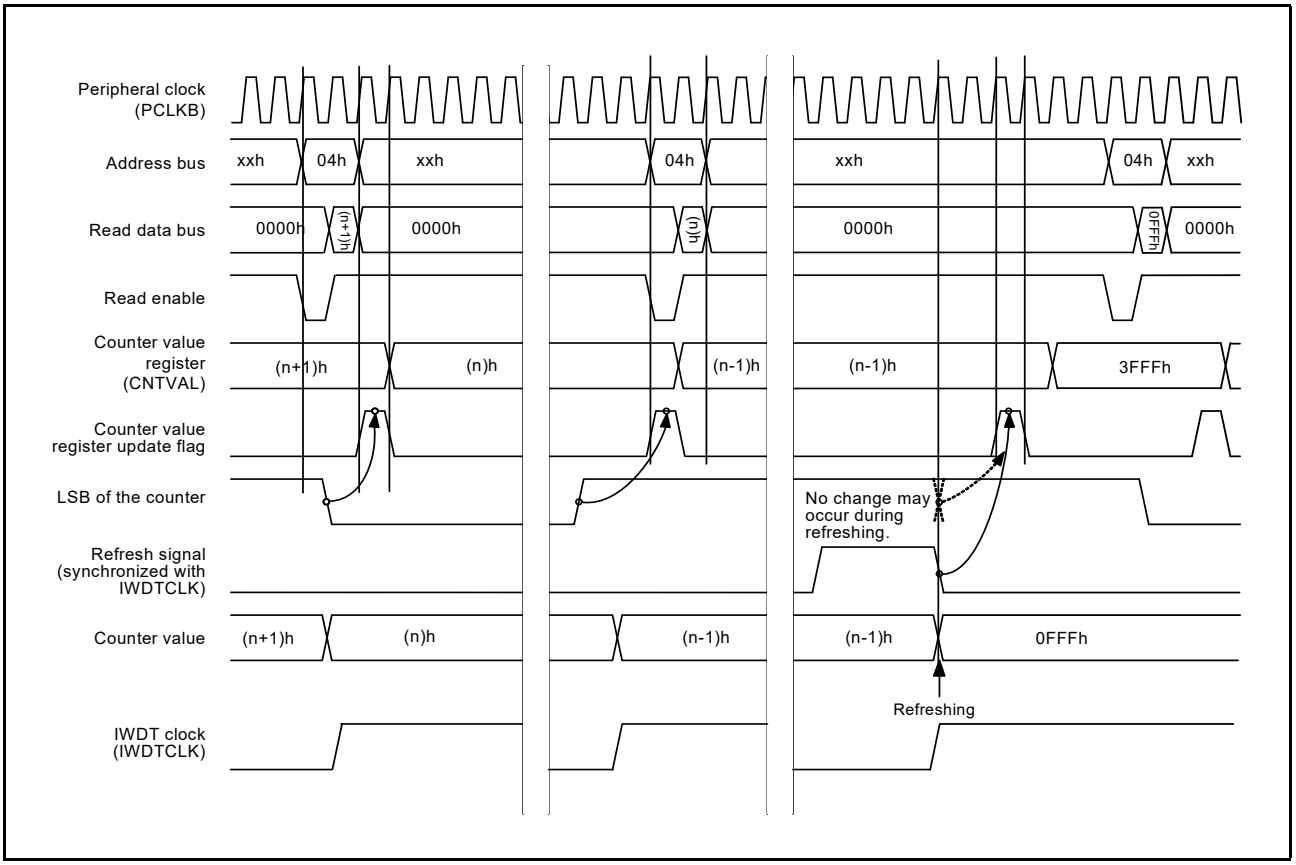

Figure 27.7 Processing for Reading IWDT Counter Value (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b)

27.4 Low-Power Consumption Control

27.4.1 Watchdog Timer Operations in Low-Power Consumption Mode Transition

Clock supply to the IWDT can be controlled during transition to the standby mode of Cortex-R4 or the sleep mode of Cortex-M3 while the down-counter of IWDT is operating.

Table 27.4 lists the IWDT operations during transition to the low-power consumption mode.

Table 27.4 IWDT Operations during Transition to Low-Power Consumption Mode <in Low-Power Consumption Mode Transition>

Low-Power Consumption Mode	IWDT Clock Supply	IWDT Operation
Cortex-R4 standby	√	√
Cortex-M3 sleep	√	√

√: Operating

28. Ethernet MAC (ETHERC)

This LSI has Ethernet MAC (ETHERC) with an accelerator.

28.1 Overview

Table 28.1 describes the Ethernet MAC (ETHERC) functions.

Table 28.1 ETHERC Specifications

Item	Specifications
Functions	• 1 port*1 • IEEE802.3 is supported • 10BASE and 100BASE are supported • Full duplex and half duplex are supported • Automatic pause packet transmission function • Auto broadcast suspension function by the pause packet reception • MII/RMII interface is supported
Interrupt sources	Seven sources: • Ethernet MII management access completion interrupt • Ethernet pause packet transmission completion interrupt • Ethernet transmission completion interrupt • RX FIFO overflow interrupt • TX FIFO underflow interrupt • TX FIFO error interrupt • Ethernet reception frame error interrupt

Note 1. Use of two ports is possible with the Ethernet switch function. For details, see section 28.2.1.4, MAC Select Register (MACSEL).

Note: 1 Gbps mode is not supported because the supported interfaces are only MII and RMII. However, when connecting to an Ethernet switch, use 1 Gbps mode because GMII is used for connection.

Figure 28.1 and Figure 28.2 are block diagrams of the ETHERC. Modules, registers, and other items indicated in gray are described in section 29, Ethernet Switch and section 30, EtherCAT Slave Controller (optional).

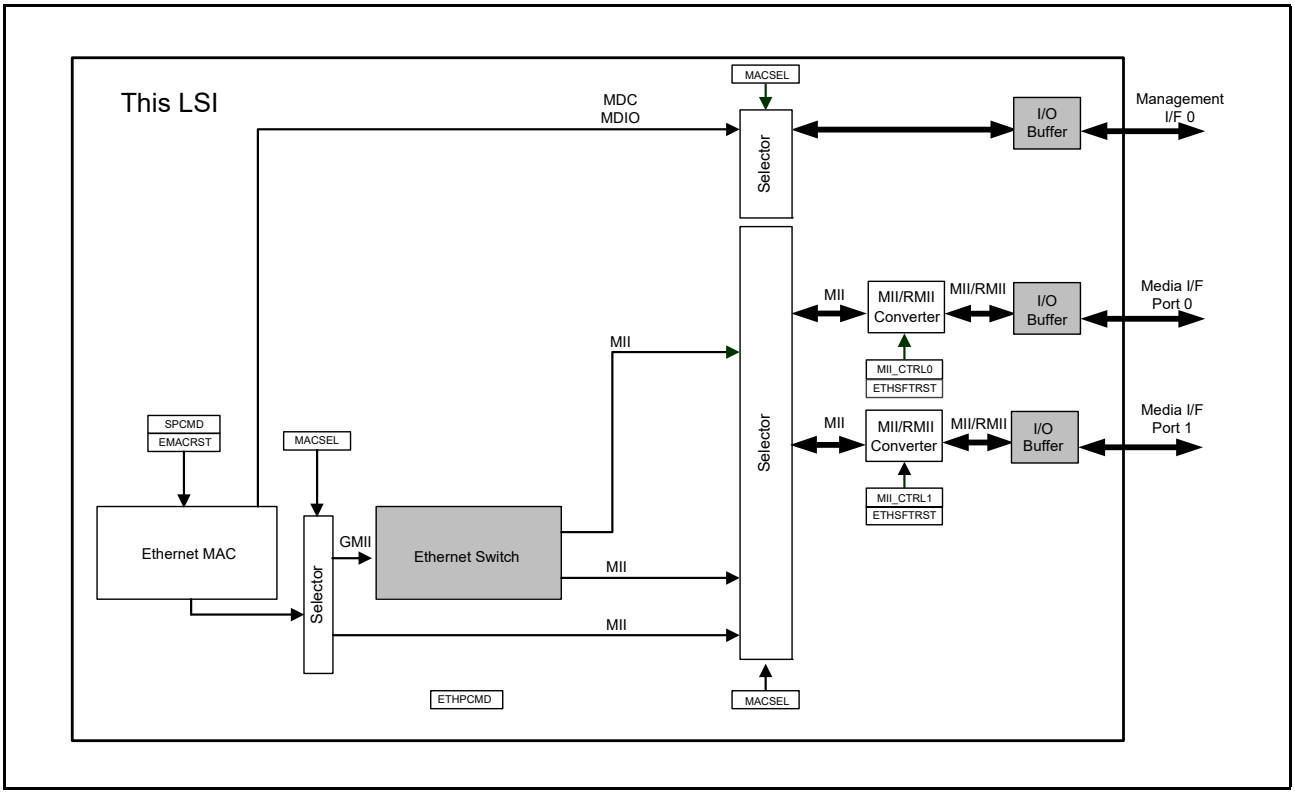

Figure 28.1 Block Diagram of the ETHERC

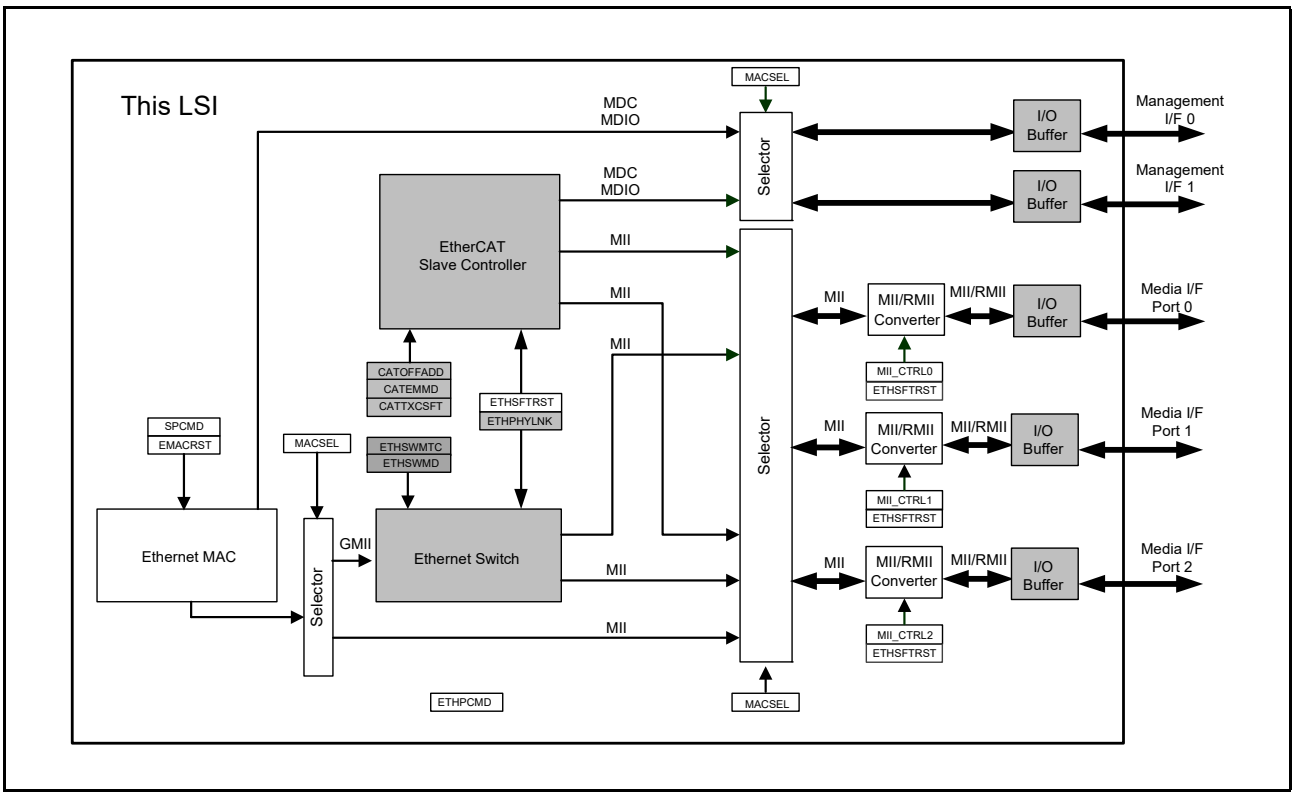

Figure 28.2 Block Diagram of the ETHERC (for products incorporating an EtherCAT (optional))

Table 28.2 lists the input/output pins of the ETHERC.

Table 28.2 Input/Output Pins of the ETHERC

Pin Name	I/O	Description
ETH0_TXC, ETH1_TXC, ETH2_TXC	Input	10M/100M transmission clock (2.5 MHz/25 MHz) input pin
ETH0_TXEN, ETH1_TXEN, ETH2_TXEN	Output	Transmission enable signal output pin
ETH0_TXER, ETH1_TXER, ETH2_TXER	Output	Transmission error signal output pin
ETH0_TXD0 to ETH0_TXD3, ETH1_TXD0 to ETH1_TXD3, ETH2_TXD0 to ETH2_TXD3	Output	Transmission data signal output pin
ETH0_RXC, ETH1_RXC, ETH2_RXC	Input	Reception clock input pin
ETH0_RXDV, ETH1_RXDV, ETH2_RXDV	Input	Received data enable signal input pin
ETH0_RXER, ETH1_RXER, ETH2_RXER	Input	Received data error signal input pin
ETH0_RXD0 to ETH0_RXD3, ETH1_RXD0 to ETH1_RXD3 ETH2_RXD0 to ETH2_RXD3	Input	Received data signal input pin
ETH0_CRS, ETH1_CRS, ETH2_CRS	Input	Carrier sense signal input pin
ETH0_COL, ETH1_COL, ETH2_COL	Input	Collision detection signal input pin
ETH_MDC, MII2_MDC	Output	Management interface clock output pin
ETH_MDIO, MII2_MDIO	I/O	Management data signal input/output pin
PHYLINK0, PHYLINK1	Input	PHY Link signal input pin
ETHSWSECOUT	Output	Ethernet switch SYNCOUT signal output pin
PHYRESETOUT#, PHYRESETOUT2#	Output	Output the PHY RESET signal (PHYRESETOUT#: for Ether0 and Ether1, PHYRESETOUT2#: for Ether2)

Table 28.3 and Table 28.4 list the names of the I/O pin functions for each of the modules.

Table 28.3 I/O Pin Functions for ETHERC (in MII Mode)

Media I/F	Port 0	Port 1	Port 2
10M/100M transmission clock input	ETH0_TXC	ETH1_TXC	ETH2_TXC
Transmission enable output	ETH0_TXEN	ETH1_TXEN	ETH2_TXEN
Transmission error output	ETH0_TXER	ETH1_TXER	ETH2_TXER
Transmission data output	ETH0_TXD0 to 3	ETH1_TXD0 to 3	ETH2_TXD0 to 3
Reception clock input	ETH0_RXC	ETH1_RXC	ETH2_RXC
Received data enable input	ETH0_RXDV	ETH1_RXDV	ETH2_RXDV
Received data error input	ETH0_RXER	ETH1_RXER	ETH2_RXER
Received data input	ETH0_RXD0 to 3	ETH1_RXD0 to 3	ETH2_RXD0 to 3
Carrier sense input	ETH0_CRS	ETH1_CRS	ETH2_CRS
Collision detection input	ETH0_COL	ETH1_COL	ETH2_COL

Management I/F	Port 0	Port 1	Port 2
Management interface clock output	ETH_MDC		MII2_MDC
Management data input/output	ETH_MDIO		MII2_MDIO

Others	Port 0	Port 1	Port 2
PHY Link input	PHYLINK0	PHYLINK1	—
Ethernet switch SYNCOUT output	ETHSWSECOUT		—
PHY reset output	PHYRESETOUT#		PHYRESTOUT2#
External clock output for Ethernet PHY*1	CLKOUT25M0	CLKOUT25M1	CLKOUT25M2

Note 1. The clock frequency is 25 MHz in MII mode.

Table 28.4 I/O Pin Functions for ETHERC (in RMII Mode)

Media I/F	Port 0	Port 1	Port 2
Transmission enable output	ETH0_TXEN	ETH1_TXEN	ETH2_TXEN
Transmission data output	ETH0_TXD0, 1	ETH1_TXD0, 1	ETH2_TXD0, 1
Carrier sense/received data enable input	ETH0_RXDV	ETH1_RXDV	ETH2_RXDV
Received data error input	ETH0_RXER	ETH1_RXER	ETH2_RXER
Received data input	ETH0_RXD0, 1	ETH1_RXD0, 1	ETH2_RXD0, 1

Management I/F	Port 0	Port 1	Port 2
Management interface clock output	ETH_MDC		MII2_MDC
Management data input/output	ETH_MDIO		MII2_MDIO

Others	Port 0	Port 1	Port 2

Ethernet switch SYNCOUT output	ETHSWSECOUT		—
PHY reset output	PHYRESETOUT#		PHYRESTOUT2#
External clock output for Ethernet PHY*1	CLKOUT25M0	CLKOUT25M1	CLKOUT25M2

Note 1. The clock frequency is 50 MHz in RMII mode.

28.2 Register Descriptions

28.2.1 Ethernet interface selection registers

28.2.1.1 System Protect Command Register (SPCMD)

The SPCMD register is used to control writing to write-protected registers.
For details, see section 28.3.6, Protect Command Register.
The SPCMD register allows read/write access in 32-bit units.

Address(es): ETHERC.SPCMD A00F 2100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PROTREL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTREL	Protection Unlock Enable	Permits write access to a write-protected register. Writing is allowed in a specific instruction sequence only. 1: Enables write access. 0: Disables write access (write-protected).	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: After data is written to the write-protected register, be sure to clear the SPCMD.PROTREL bit (to 0) to enable protection again.

28.2.1.2 Ethernet MAC Reset Register (EMACRST)

The EMACRST register is used to control the reset status of ETHERC by software. After reset is released, the EMACRST bit is initialized to 0. This means that ETHERC is still in the reset state. After Ethernet MAC selection or PHY mode setting has been completed, use this register to release the reset state.
To reset ETHERC during operation, after 0s are written to this register, use software to read the EMACRST bit. Then, after confirming that the bit is set to 0, write 1 to release the reset state.
This register is write-protected by the system protect command register (SPCMD). To write to this register, use the SPCMD register to release write protection. For products with a built-in R-IN engine, this register also resets the HW-RTOS.

Address(es): ETHERC.EMACRST A00F 2110h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	EMACRST	Ethernet MAC Reset Control	Controls the reset state of Ethernet MAC. 1: Reset-released state 0: Reset state (initial value)	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

28.2.1.3 Ethernet System Protect Command Register (ETSPCMD)

The ETSPCMD register is used to control writing to write-protected registers.
For details, see section 28.3.6, Protect Command Register.
The ETSPCMD register allows read/write access in 32-bit units.

Address(es): ETHERC.ETSPCMD A00B F000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PROTREL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTREL	Protection Unlock Enable	Permits write access to a write-protected register. Writing is allowed in a specific instruction sequence only. 1: Enables write access. 0: Disables write access (write-protected).	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note: After data is written to the write-protected register, be sure to clear the ETSPCMD.PROTREL bit (to 0) to enable protection again.

28.2.1.4 MAC Select Register (MACSEL)

The MACSEL register is used to select the function of the Ethernet interface.
Before changing the settings of this register, use the EMACRST register to place Ethernet MAC in the reset state. After changing the register settings, be sure to reset PHY, and then specify the MAC settings. This register allows read/written access in 32-bit units. For the configuration of the MAC function, see Figure 28.1, Figure 28.2, Table 28.5, and Table 28.6.
This register is write-protected by the Ethernet system protect command register (ETSPCMD). To write to this register, use the ETSPCMD register to release write protection.

Address(es): ETHERC.MACSEL A00B F004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

000	Ethernet Switch Port 0	Ethernet Switch Port 1	EthernetMAC
011	Not used	EthernetMAC (if the switch function is not used)	EthernetMAC
Other than above	Setting prohibited		

28.2.1.5 MII Control Register (MII_CTRLn) (n = 0 to 2)

The MII_CTRLn register is used to control the MII/RMII converter. This register allows read/written access in 32-bit units.

Address(es): ETHERC.MII_CTRL0 A00B F008h, ETHERC.MII_CTRL1 A00B F00Ch, ETHERC.MII_CTRL2 A00B F010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	RMII_CRS_MODE	—	FULLD	—	—	—	MODE[4:0]				
Value after reset:	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	MODE[4:0]	MII Converter Mode Select	Sets the mode of the MII converter. b4 b0 x_0000: MII mode 1_0100: RMII mode (10 Mbps)*1 1_0101: RMII mode (100 Mbps)*1 Others: Setting prohibited	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	FULLD	Duplex Mode Setting	Specifies the Duplex Mode settings. 0: Half duplex 1: Full duplex (initial value)	R/W
b9	—	Reserved	When used in RMII mode, be sure to set this bit to 1.	R/W
b10	RMII_CRS_MODE	CRS Determination Condition Select	Sets the condition for determining the carrier sense (CRS) signal. This bit takes effect in RMII mode only. CRS determination condition 0: CRS | TXEN 1: CRS | RXDV | TXEN (initial value)	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. For use in RMII mode, be sure to set b9 to 1.

28.2.1.6 Ethernet Peripheral Reset Register (ETHSFTRST)

The ETHSFTRST register is used to control the reset states of the RMII converter, EtherCAT*1, Ethernet switch, and other Ethernet peripheral circuits by software.

After reset is released, all bits are initialized to 0. Therefore, all Ethernet peripheral circuits, including the RMII converter, EtherCAT*1, and Ethernet switch, are placed in the reset state. After Ethernet MAC selection or PHY mode setting has been completed, use this register to release the reset state of each circuit.

To reset Ethernet peripheral circuits during operation, after 0s are written to this register, use software to read the target bits. Then, after confirming that the bits are set to 0, write 1 to release the reset state.

This register is write-protected by the Ethernet system protect command register (ETSPCMD). To write to this register, use the ETSPCMD register to release write protection.

Note 1. Optional

Address(es): ETHERC.ETHSFTRST A00B F118h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	—	MIICRST	PHYRST2*1	PHYRST	SWRST	CATRST*1
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Note 1. These bits are only for products incorporating an EtherCAT (optional).

Bit	Symbol	Bit Name	Description	R/W
b0	CATRST*1	EtherCAT Reset Control (only for products incorporating an EtherCAT (optional))	Resets EtherCAT. 1: Reset-released state 0: Reset state (initial value)	R/W
b1	SWRST	Ethernet Switch Reset Control	Resets the Ethernet switch. 1: Reset-released state 0: Reset state (initial value)	R/W
b2	PHYRST	PHYRESETOUT# Pin Reset Control	Resets the PHYRESETOUT# output pin. For products with EtherCAT (an optional function), the RESETOUT signals are output from EtherCAT with their functions being logically ORed. 1: Reset-released state 0: Reset state (initial value)	R/W
b3	PHYRST2*1	PHYRESETOUT2# Pin Reset Control (only for products incorporating an EtherCAT (optional))	Resets the PHYRESETOUT2# output pin. 1: Reset-released state 0: Reset state (initial value)	R/W
b4	MIICRST	RMII Converter Reset Control	Resets the RMII converter. 1: Reset-released state 0: Reset state (initial value)	R/W
b31 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit is reserved for products other than those incorporating an EtherCAT (optional). It is read as 0. The write value should always be 0.

28.2.2 Ethernet MAC Control Register

28.2.2.1 MIIM Register (GMAC_MIIM)

The GMAC_MIIM register is used to control register access to each Ethernet PHY. For access to this register, clear the MSTPCRB18 bit in the MSTPCRB register to release the Ethernet MAC from the module-stop state, and then follow the procedure below.

For write access:

1. Start of a write operation: Set the RWDV bit to 1; set the PHYADDR[4:0] bits to the PHY address; set the REGADDR[4:0] bits to the PHY register address; set the DATA[15:0] bits to the write data.
2. Wait for the operation to finish: Wait until 1 is read from the RWDV bit.
3. Wait for the operation to finish: The write operation finishes when 1 is read from the RWDV bit.

For read access:

1. Start of a read operation: Set the RWDV bit to 0; set the PHYADDR[4:0] bits to the PHY address; set the REGADDR[4:0] bits to the PHY register address.
2. Wait for the operation to finish: Wait until 1 is read from the RWDV bit.
3. Wait for the operation to finish: When 1 is read from the RWDV bit and valid data is read from the DATA[15:0] bits, the read operation finishes.

Note: The setting of the GMAC_MIIM register is only effective when the Ethernet MAC or Ethernet switch port is selected by the MAC select register (MACSEL). In other cases, writing to this register has no effect and the value read is undefined.

Address(es): ETHERC.GMAC_MIIM A00F 00A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	RWDV	PHYADDR[4:0]					REGADDR[4:0]				
Value after reset:	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	DATA[15:0]	Data	Indicates write data or read data.	R/W
b20 to b16	REGADDR [4:0]	PHY Register Address	Specifies the register address of the PHY to be accessed. Because this is a write-only bit, the value read from the bit is undefined.	W
b25 to b21	PHYADDR [4:0]	PHY Address	Specifies the address of the PHY to be accessed. Because this is a write-only bit, the value read from the bit is undefined.	W
b26	RWDV	Read/Write Operation	Reading or writing starts when the values shown below are written to this bit. Set the other effective bits in this register at the same time as the setting of this bit. 1: Starts a write operation. 0: Starts a read operation.	W
			After a read/write operation has started, the status of the operation can be checked by reading the value of this bit.*1 1: Operation is completed. 0: Waiting for the operation to start.	R

Bit	Symbol	Bit Name	Description	R/W
b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. After reset is released, the RWDV bit is set to 1. However, the values held by the DATA[15:0] bits at this time are not valid. To use the RWDV bit to check the status correctly, make sure that the value is read from the bit after the operation has started.

28.2.2.2 TX ID Register (GMAC_TXID)

The GMAC_TXID register is used to indicate the ID of the transmission frame for the GMAC_TXRESULT register. To check the transmission frame result ID, be sure to read this register before reading the GMAC_TXRESULT register. If the GMAC_TXRESULT register is read first, the transmission frame result is updated. Therefore, the updated transmission frame ID is read from the GMAC_TXID register.

Address(es): ETHERC.GMAC_TXID A00F 000Ch

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TXID[31:0]	Transmission Frame ID	Indicates the ID of the transmission frame for the TX RESULT register.	R

28.2.2.3 TX RESULT Register (GMAC_TXRESULT)

The GMAC_TXRESULT register is used to indicate the transmission frame result.
The flags in this register are only valid when the TRBMODE[1:0] bits in the GMAC_TXMODE register are 00 or 01.
The results for the transmission of a frame are held in the transmission result buffer at the same time as the Ethernet transmission complete interrupt (ETHIT) is generated. The transmission result buffer can hold the information for four frames. The results of transmission for a next frame are acquired from the transmission result buffer by reading this register. The GMAC_TXFIFO.TRBFR[2:0] bits indicate the number of frames for which the transmission result buffer currently holds information.
When transmission proceeds while the buffer already holds information for four frames, the transmission is illicit, so a TX-FIFO error interrupt (ETHTFIE) is generated. Read the frame transmission information appropriately so that errors are not generated while this register is valid.

Address(es): ETHERC.GMAC_TXRESULT A00F 0010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b0	FIFOUFLOW	FIFO Underflow Status	An FIFO underflow occurred during transmission.	R
b4 to b1	RETRYN[3:0]	Retry Count Status	Retry count	R
b5	LCOLLIS	Late Collision Detection Status	Late Collision was detected.	R
b6	UNDERFW	Frame Length Underflow Status	A frame shorter than the minimum frame length was written to the transmit FIFO.	R
b7	OVERFW	Frame Length Overflow Status	A frame longer than 1,518 octets was written to the transmit FIFO.	R
b8	CSERR	Carrier Sense Error Status	Disappearance of the carrier has been detected.	R
b9	MCOLLIS	Multi-Collision Detection Status	Multiple collisions were experienced.	R
b10	SCOLLIS	Single-Collision Detection Status	1 collision was experienced.	R
b11	TFAIL	Transmission Fail Status	Transmission failed because an Excessive Collision error occurred (16 consecutive failures in re-transmission).	R
b12	TABT	Transmission Abort Status	Transmission abort occurred.	R
b13	TCMP	Transmission Completion Status	Transmission finished.	R
b31 to b14	—	Reserved	These bits are read as 0.	R

28.2.2.4 MODE Register (GMAC_MODE)

The GMAC_MODE register is used to control the operating mode of ETHERC.

Address(es): ETHERC.GMAC_MODE A00F 0020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	REMPTH[1:0]		RFULLTH[1:0]		RRTTH[2:0]			—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b8 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b9	RRTTH[2:0]	RX FIFO Read Trigger Threshold	The RRT bit in the GMAC_RXFIFO register is set to 1 when the SFRXFIFO bit is 0 and the number of words in the FIFO is greater than or equal to the value corresponding to the setting as shown below. b11 b10 b9 0 0 0: 4 words 0 0 1: 8 words 0 1 0: 16 words 0 1 1: 32 words 1 0 0: 64 words 1 0 1: 128 words 1 1 0: 256 words 1 1 1: 512 words	R/W
b13, b12	RFULLTH[1:0]	Receive Almost Full Threshold	The RFULL bit in the GMAC_RXFIFO register is set to 1 when the number of empty words in the FIFO buffer is less than or equal to the value corresponding to the setting as shown below. b13 b12 0 0: 4 words 0 1: 8 words 1 0: 16 words 1 1: 32 words	R/W
b15, b14	REMPTH[1:0]	Receive Almost Empty Threshold	The REMP bit in the GMAC_RXFIFO register is set to 1 when the number of words in the FIFO is less than or equal to or the value corresponding to the setting as shown below. b15 b14 0 0: 4 words 0 1: 8 words 1 0: 16 words 1 1: 32 words	R/W
b27 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b28	RAMASKEN	RX Address Mask Enable	1: Enables the function that can be set by the BITMSK[7:0] bits of the GMAC_ADRnB register (comparative mask function for Destination Address[7:0]). (n = 0 to 15) 0: Disables the above function.	R/W

Bit	Symbol	Bit Name	Description	R/W
b29	SFRXFIFO	Store & Forward For RX FIFO	1: Store & Forward mode The reception DMA controller starts to operate after data up to the end of the frame are written to the RX FIFO buffer. 0: Cut-through mode The reception DMA controller starts to operate when the number of words set in the RRTTH[2:0] bits is written to the RX FIFO buffer.	R/W
b30	MFILLTEREN	Multicast Filtering Enable	1: Discards multicast address frames that are not registered in MAC address registers (GMAC_ADRnA and GMAC_ADRnB). (n = 0 to 15) 0: Includes all multicast address frames.	R/W
b31	AFILLTEREN	Address Filtering Enable	1: Enables address filtering.*1 0: Includes all address frames.	R/W

Note 1. Even if address filtering is enabled, MAC control frames (pause packets, etc.) are always received whether or not the addresses are registered in the MAC address register. A MAC control frame is a frame having the destination address 01-80-C2-00-00-01.

28.2.2.6 TX MODE Register (GMAC_TXMODE)

The GMAC_TXMODE register is used to control frame transmission. One word in the transmission FIFO buffer is 64 bits and the buffer has a capacity of 4 Kbytes.

Address(es): ETHERC.GMAC_TXMODE A00F 0028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RTRANSDEN	LPTXEN	SF	SPTXEN	RTRANSLC	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TEMPTH[2:0]			TFULLTH[1:0]		—	TRBMODE[1:0]		—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7, b6	TRBMODE[1:0]	Transmission Result Buffer Mode	Controls how to write the transmission result to the GMAC_TX RESULT register. b7 b6 0 0: The result is always written. 0 1: The result is written only when an error occurred. 1 0: The result is never written. Others: Setting prohibited	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10, b9	TFULLTH[1:0]	Transmit Almost Full Threshold	The TFULL bit in the GMAC_TXFIFO register is set to 1 when the number of empty words in the TX FIFO buffer is less than or equal to the value corresponding to the setting as shown below. b10 b9 0 0: 4 words 0 1: 8 words 1 0: 16 words 1 1: 32 words	R/W
b13 to b11	TEMPTH[2:0]	Transmit Almost Empty Threshold	The TEMP bit in the GMAC_TXFIFO register is set to 1 when the number of data words in the TX FIFO buffer is less than or equal to the value corresponding to the setting as shown below. b13 b12 b11 0 0 0: 4 words 0 0 1: 8 words 0 1 0: 16 words 0 1 1: 32 words 1 0 0: 64 words 1 0 1: 128 words 1 1 0: 256 words 1 1 1: 512 words	R/W
b26 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b27	RTRANSLC	Retransmission at Late Collision	1: Performs retransmission if a Late Collision occurs. 0: Aborts processing if a Late Collision occurs.	R/W
b28	SPTXEN	Short Packet TX Enable	1: Permits transmission of frames that are shorter than the length prescribed by IEEE802.3. 0: Prohibits transmission of frames that are shorter than the length prescribed by IEEE802.3.	R/W
b29	SF	Store & Forward	1: Starts transmission after the data up to the end of the frame is written to TX FIFO. Use this setting to use TCP/IP Accelerator. 0: Setting prohibited	R/W

Bit	Symbol	Bit Name	Description	R/W
b30	LPTXEN	Long Packet TX Enable	1: Permits transmission of frames that are longer than the length prescribed by IEEE802.3.*1 0: Prohibits transmission of frames that are longer than the length prescribed by IEEE802.3.	R/W
b31	RTRANSDEN	No Retransmission	1: Does not perform retransmission when a collision occurs. 0: Performs retransmission as prescribed when a collision occurs.	R/W

Note 1. When the management tag insertion function of the Ethernet switch is enabled (the SWTAGEN bit in the ETHSWMTC register = 1), the size of the frame may exceed the maximum frame size of 1518 bytes. Therefore, the LPTXEN bit must be set to 1 in this case.
Note that the maximum frame size before insertion of the management tag should still be within 1518. For details, see section 28.4.7, Frame with Size Exceeding 1518 Bytes.

28.2.2.7 RESET Register (GMAC_RESET)

The GMAC_RESET register is a trigger register that is used to reset the ETHERC module by software.
The module is reset by setting all bits to 1. All bits will automatically be initialized to 0 afterward.
The time required for the completion of a reset depends on the MAC operating mode as shown below.

- Operation at 1 Gbps (125 MHz): 60 ns
- Operation at 100 Mbps (25 MHz): 200 ns
- Operation at 10 Mbps (2.5 MHz): 2000 ns

Address(es): ETHERC.GMAC_RESET A00F 0030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b31 to b0	PPDATA5 [31:0]	Pause Packet Data 5	Specifies the 20th to 17th bytes of the pause packet to be sent. Data is sent in LSB-first order.	R/W

28.2.2.9 RX FLOW CONTROL Register (GMAC_FLWCTL)

The setting of the GMAC_FLWCTL register determines whether or not transmission is suspended after a pause packet is received.

When a pause packet is received while suspension is enabled, transmission is suspended for the time specified by the pause packet.

Address(es): ETHERC.GMAC_FLWCTL A00F 0098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	PPRXEN	Pause Packet Reception Function Enable	1: Enables the pause packet reception function. 0: Disables the pause packet reception function.	R/W

28.2.2.10 PAUSE Packet Register (GMAC_PAUSPKT)

The GMAC_PAUSPKT register is used to control pause packet transmission.

Writing 1 to the PPR bit causes transmission of the data set in the PAUSE packet data register (GMAC_PAUSEn). The bit is cleared to 0 when the transmission is completed.

Address(es): ETHERC.GMAC_PAUSPKT A00F 009Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b30 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	PPR	Pause Packet Transmission Trigger	Controls pause packet transmission. 0: Performs nothing. 1: Starts pause packet transmission.	R/W

28.2.2.11 MAC Address Registers (GMAC_ADRnA and GMAC_ADRnB) (n = 0 to 15)

The GMAC_ADRnA and GMAC_ADRnB registers are used to set MAC addresses.
A maximum of 16 addresses can be registered. Multiple addresses can be filtered by using the BITMSK[7:0] bits of the GMAC_ADRnB register.

- GMAC_ADRnA

Address(es): ETHERC.GMAC_ADR0A A00F 0100h, ETHERC.GMAC_ADR1A A00F 0108h, ETHERC.GMAC_ADR2A A00F 0110h, ETHERC.GMAC_ADR3A A00F 0118h, ETHERC.GMAC_ADR4A A00F 0120h, ETHERC.GMAC_ADR5A A00F 0128h, ETHERC.GMAC_ADR6A A00F 0130h, ETHERC.GMAC_ADR7A A00F 0138h, ETHERC.GMAC_ADR8A A00F 0140h, ETHERC.GMAC_ADR9A A00F 0148h, ETHERC.GMAC_ADR10A A00F 0150h, ETHERC.GMAC_ADR11A A00F 0158h, ETHERC.GMAC_ADR12A A00F 0160h, ETHERC.GMAC_ADR13A A00F 0168h, ETHERC.GMAC_ADR14A A00F 0170h, ETHERC.GMAC_ADR15A A00F 0178h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	—	Reserved	These bits are read as 0.	R
b26 to b24	TRBFR[2:0]		Indicates the number of frames existing in the transmission result buffer.	R
b29 to b27	TSTATUS [2:0]	TX FIFO Status	Indicates the status of TX FIFO. The meanings of bit settings are as follows: b2 b1 b0 1 0 0: ACC NEW FR: TX FIFO can accept new frames. 1 0 1: WRITE ENABLE: TX FIFO can continue to accept frame data. 1 1 0: CMPLT: Inclusion of one frame was completed. 1 1 1: FULL: TX FIFO is in FIFO Full status. 0 x x: STOP: TX FIFO is inactive (or being initialized).	R
b30	TEMP	TX FIFO Almost Empty	This bit is set to 1 when the number of data words in TX FIFO is equal to or less than the threshold value set by the TEMPTH[2:0] bits of the GMAC_TXMODE register.	R
b31	TFULL	TX FIFO Almost Full	This bit is set to 1 when the number of empty words in the TX FIFO buffer is less than or equal to the threshold set by the TFULLTH[1:0] bits in the GMAC_TXMODE register.	R

28.2.2.14 TCPIPACC Register (GMAC_ACC)

The GMAC_ACC register is used to control operation of the TCP/IP accelerator.

Address(es): ETHERC.GMAC_ACC A00F 0208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	RTCPIPACC	TTCPIPEN	RTCPIPEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	RTCPIPEN	RX TCPIP Accelerator Enable	1: RX TCPIP Enable Enables the RX TCPIP accelerator. 0: RX TCPIP Disable Disables the RX TCPIP accelerator. Padding is not inserted in the MAC headers.	R/W
b1	TTCPIPEN	TX TCPIP Accelerator Enable	1: TX TCPIP Enable Enables the TX TCPIP accelerator. 0: TX TCPIP Disable Disables the TX TCPIP accelerator. The padding in the MAC header is also disabled.	R/W
b2	RTCPIPACC	RX TCPIP Checksum Disable	1: RX TCPIPACC Off Disables checksum support for the RX TCPIP accelerator. Padding in the MAC header is inserted. 0: Checksum support for the RX TCPIP accelerator continues to be enabled (initial value).	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

28.2.2.15 RX MAC ENABLE Register (GMAC_RXMAC_ENA)

The GMAC_RXMAC_ENA register is used to control operation of the receive MAC.

Address(es): ETHERC.GMAC_RXMAC_ENA A00F 0220h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	RMACEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RMACEN	RX MAC ENABLE	1: Enables reception (initial value). 0: Disables reception.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

28.2.2.16 LPI Mode Control Register (GMAC_LPI_MODE)

The GMAC_LPI_MODE register is used to control LPI (Low Power Idle) mode. When the LPMEN bit is 1, if transmission is not requested for a time longer than that specified by the LPRDEF bits in the GMAC_LPI_TIMING register, an LPI request is automatically issued to other party in the link. A transmission request being issued in LPI mode leads to exit from the LPI mode. After that, frames are transmitted after the time specified by the LPWTIME bit in the GMAC_LPI_TIMING register has elapsed.

Do not use this register to set LPI mode if ETHERC is connected via an Ethernet switch.

Address(es): ETHERC.GMAC_LPI_MODE A00F 0224h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LPMEN	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	LPMEN	Low Power Idle Mode	1: ETHERC operates in LPI mode. 0: ETHERC does not operate in LPI mode.	R/W

28.2.2.17 LPI CLIENT Timing Control Register (GMAC_LPI_TIMING)

The GMAC_LPI_TIMING register is used to control the signal timing in LPI mode.
Note that this register is not used if ETHERC is connected via an Ethernet switch.

Address(es): ETHERC.GMAC_LPI_TIMING A00F 0228h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LPRDEF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LPWTIME[15:0]															
Value after reset:	0	0	0	0	1	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	LPWTIME [15:0]	Low Power Idle Wake Time	Sets the time before frames can be sent to a link after the IDLE signal is sent to the link when LPI is terminated for the link partner. In Gigabit mode, a value can be set in 8 nanoseconds. In 100 Mbps mode, a value can be set in 40 nanoseconds.	R/W
b31 to b16	LPRDEF [15:0]	Low Power Idle Request Deferral	Sets the delay time before an LPI request is sent to the link partner. In Gigabit mode, a value can be set in 8 nanoseconds. In 100 Mbps mode, a value can be set in 40 nanoseconds.	R/W

28.2.2.18 Reception Buffer Information Register (BUFID)

The BUFID register is a status register that indicates the information on the reception buffer (such as whether or not it contains received data, the address of the buffer, and the number of words it holds). On completion of transfer by the reception MACDMA, up to 64 items of reception buffer information are written to this register. Storage of the data in the reception buffer information register leads to the generation of an Ethernet MACDMA reception complete interrupt (ETHDMAIR). This interrupt remains active until the NOEMP bit is cleared to 0 after no received data remains to be read from the buffers.

This register indicates the information of the next received data every time it is read. 0 is read from this register if there are no received data.

Address(es): ETHERC.BUFID A00F 1100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	NOEMP	—	—	VALID	WORD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADDR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ADDR[15:0]	Reception Buffer Address Data	Reception buffer address (bits 26 to 11)	R
b27 to b16	WORD[11:0]	Receive Data Word Count	Number of words in receive data (including receive MAC information)	R
b28	VALID	Receive Data Validity	1: The receive data is valid. 0: The receive data is invalid.	R
b30, b29	—	Reserved	These bits are read as 0. The write value should be 0.	R
b31	NOEMP	Reception Buffer Data Storing Status	1: There are data in the reception buffer. 0: There are no data in the reception buffer.	R

ADDR[15:0]

The ADDR bits cannot indicate an address in the 32-bit address space. Therefore, to access a memory-mapped buffer, use an offset of 0800 0000h, where the buffer RAM starts from.

To calculate the reception buffer Address(es):

1. Obtain the value of the ADDR bits.
2. Shift the value to the left by 11 bits.
3. Add an offset of 0800 0000h.

WORD[11:0]

The number of words indicated by the WORD bits includes the number of words in the receive frame information. Therefore, the start address of the receive frame information is calculated as follows.

To calculate the start address of the receive frame information:

1. Obtain the value of the Word bits.
2. Shift the value to the right by 16 bits.
3. Add the number of words shifted in step 2 to the reception buffer address as an offset.
4. Negatively offset the value by 2 words (the size of the receive frame information).

28.2.3 Hardware Function Call Register

The hardware function call register is used to obtain a buffer. This register is also used to start transmission or reception. After argument registers (R4 to R7) are configured, a hardware function is executed by writing a command to the command register (SYSC). For details on how to configure the hardware function call register, see section 28.3.1, Hardware Functions.

Note: Registers related to hardware functions are also used to control the hardware OS accelerator.

28.2.3.1 Hardware Function System Call Register (SYSC)

When a command is written to the SYSC register, the corresponding function is executed.

Address(es): ETHERC.SYSC A00E F000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SYSC[15:0]															
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	SYSC[15:0]	System Command Specification	Specifies the hardware function to be used. One of the following functions can be specified:	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SYSC[15:0]	Functions
5000h	Acquires a long buffer.
5006h	Acquires a short buffer.
5001h	Release the whole area of the buffer.
5002h	Release the part of the buffer.
5101h	Enables DMA for the reception MAC.
5102h	Disables DMA for the reception MAC.
510Bh	Controls reception MACDMAC interrupts.
510Dh	Obtains the error source in reception MACDMAC.
5100h	Starts transfer of reception MACDMAC.
510Ch	Obtains the error source in transmission MACDMAC.
5211h	Starts DMA transfer between the buffer RAM and data RAM.
5212h	Starts replacing data in the buffer RAM or data RAM.
Other than above	Setting prohibited

28.2.3.2 Hardware Function Argument Register (Rn) (n = 4 to 7)

The Rn register is used to write an argument to be passed to a hardware function. The argument register to be used differs depending on the hardware function. For details, see section 28.3, Operation.

- R4

Address(es): ETHERC.R4 A00E F004h

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	C0STATB[31:0]	HW Function State Setting	These bits set the states of hardware function.	R/W

28.3 Operation

28.3.1 Hardware Functions

A hardware function (HWF) is defined as a function for reducing the load on the CPU, such as a DMAC or Ethernet communications accelerator.
A hardware function consists of a combination of hardware modules which are divided by function, and an overall function is defined for the set of individual hardware modules.
The following three functions are defined as hardware functions.

- Buffer allocator
- MAC DMA controller
- Buffer RAM DMA controller

Figure 28.3 is a schematic block diagram of these hardware functions in context. Solid lines in the figure indicate the flow of data, while broken lines indicate a command interface with the hardware function.

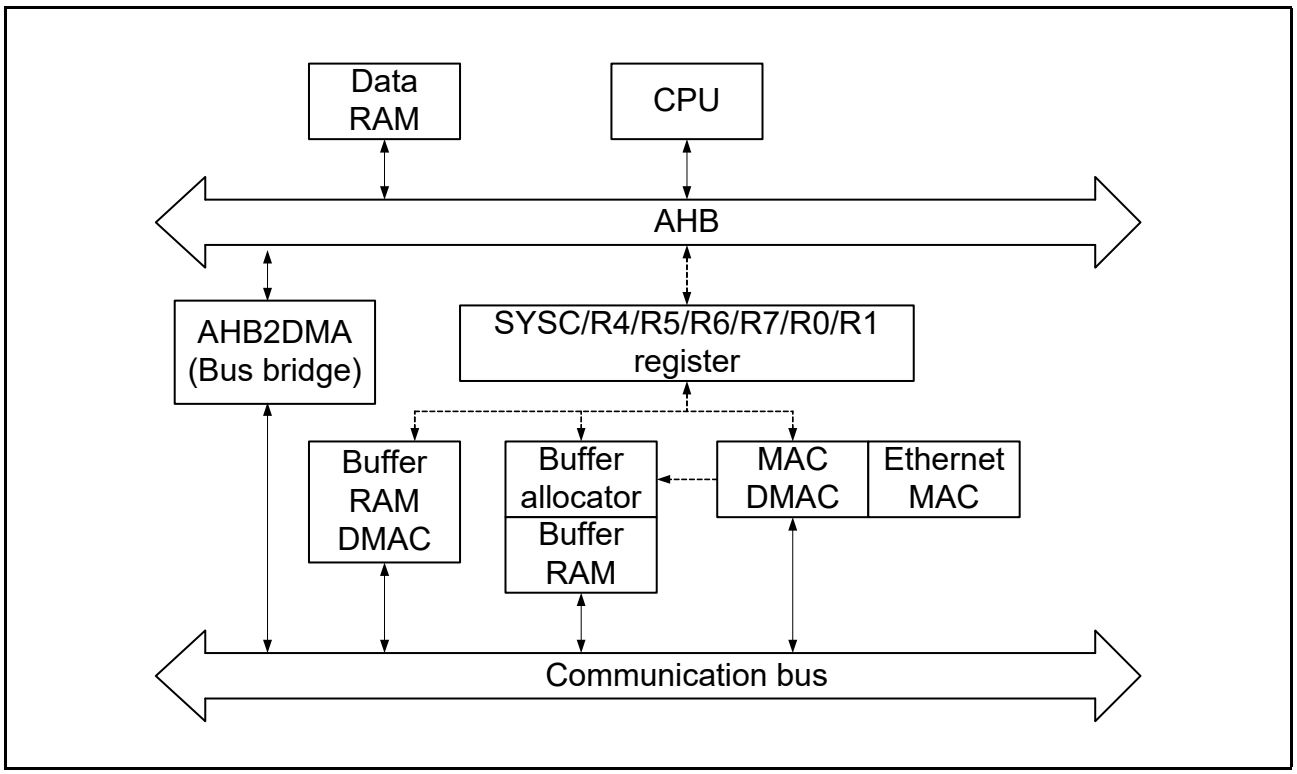

Figure 28.3 Schematic Block Diagram of the Hardware Functions

Note: For products incorporating an R-IN Engine, calling the hardware function while the hardware real-time OS is prohibited from dispatching does not successfully execute the call. Be sure to call the hardware function while dispatching is allowed. Also, the operations of the hardware real-time OS are not synchronized with the operations of the Ethernet MAC controlled by the Cortex-R4, which means, whether to allow dispatching or not is not properly controlled by the core. Therefore, do not use the hardware real-time OS while controlling the Ethernet MAC by the Cortex-R4.

28.3.1.1 Initial Settings

First, use the MSTPCRB18 bit of the module stop control register B (MSTPCRB) to release the module from the module-stop state and use the Ethernet MAC reset register (EMACRST) to release the entire Ethernet MAC module from the reset state. Also, use the Ethernet peripheral reset register (ETHSFTRST) to release the peripheral devices from the reset states. It does not matter which of EMACRST and ETHSFTRST to be set first.
After that, execute the commands listed below to set up the hardware functions.

Procedure for setting up the hardware functions
<1> Set 0000 0003h in the C0TYPE register.
<2> Set 0000 0003h in the C0STAT register.
<3> Set 0000 8004h in the CMD register.
Confirm that the bit 31 of the hardware function return value register R0 is set. Also, dummy-read the hardware function return value register R1 to clear it.
<4> Wait until 8000 0000h is read from the R0 register.
<5> Set 8000 0000h in the GMAC_RESET register to initialize the Ethernet MAC.

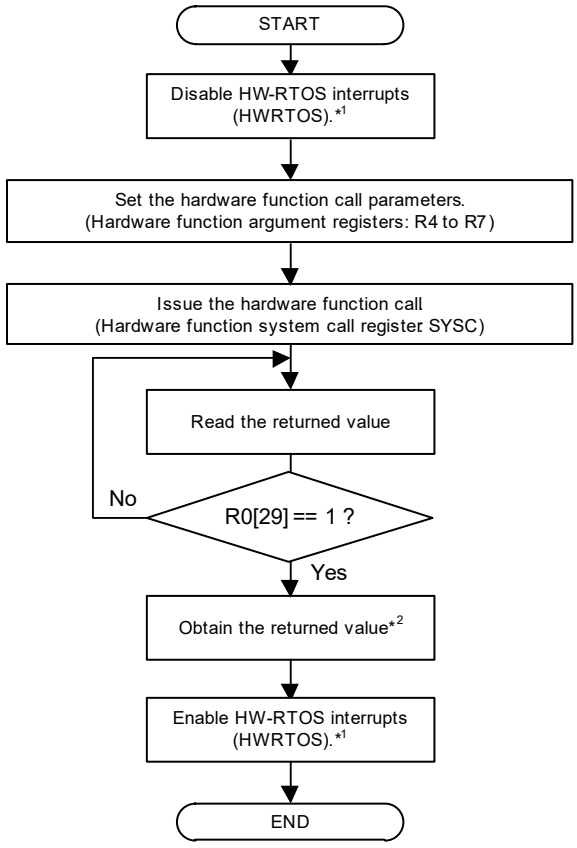
Note: When using the hardware OS accelerator function, the above settings are not required since it is controlled by setting up the OS accelerator function (only for the products incorporating and R-IN engine).

After the completion of setup, make initial settings in the registers below.

- MAC address register (→ Section 28.2.2.11)
- TX MODE register (→ Section 28.2.2.6)
- RX MODE register (→ Section 28.2.2.5)

28.3.1.2 Flow of Processing for Issuing the Hardware Function Call

If you are using a hardware function, follow the flowchart below to issue the hardware function call.



Note 1. This processing is only required when the hardware real-time OS is in use.
Note 2. The hardware function recognizes that the result registers were read by reading the R0 and R1 registers. Be sure to read R1 even in the system call which does not use R1 for storing the returned value.

Figure 28.4 Flow of Processing for Issuing the Hardware Function Call

28.3.1.3 Buffer Allocator

(1) Functional Overview

The buffer allocator is a module for controlling the buffer RAM.
The buffer RAM is a communications buffer to improve throughput in Ethernet transfer. Although the buffer RAM has 128 Kbytes, an area of 128 Mbytes is used as the logical space for the dynamic securing and releasing of memory space by the buffer allocator.
To use the buffer RAM, secure the required area (hereafter “buffer”) beforehand, and then issue the hardware function calls provided for the buffer allocator. When writing to an area which has not been secured, access by the CPU or MAC DMA controller generates an interrupt, whereas access to such area by the buffer RAM DMA controller generates an interrupt or returns an exception to the return value register R0 depending on the type of hardware function call.
To reuse a buffer after having secured it, the buffer must be released after it has been used.

The outline of the functions is as follows:

- A long buffer of up to 2048 bytes and short buffer of up to 512 bytes are available.
- When securing a buffer, the size is specified in bytes.
- When releasing a buffer, the size can be specified for the whole area or as the location of a byte (the part of the buffer from that address is released).

The segments which constitute a buffer are of 128 bytes each. The buffer allocator controls each of these 128-byte segments, and connect these segments in response to hardware function calls to provide these as buffers. Addresses are seen as continuous across contiguous segments.

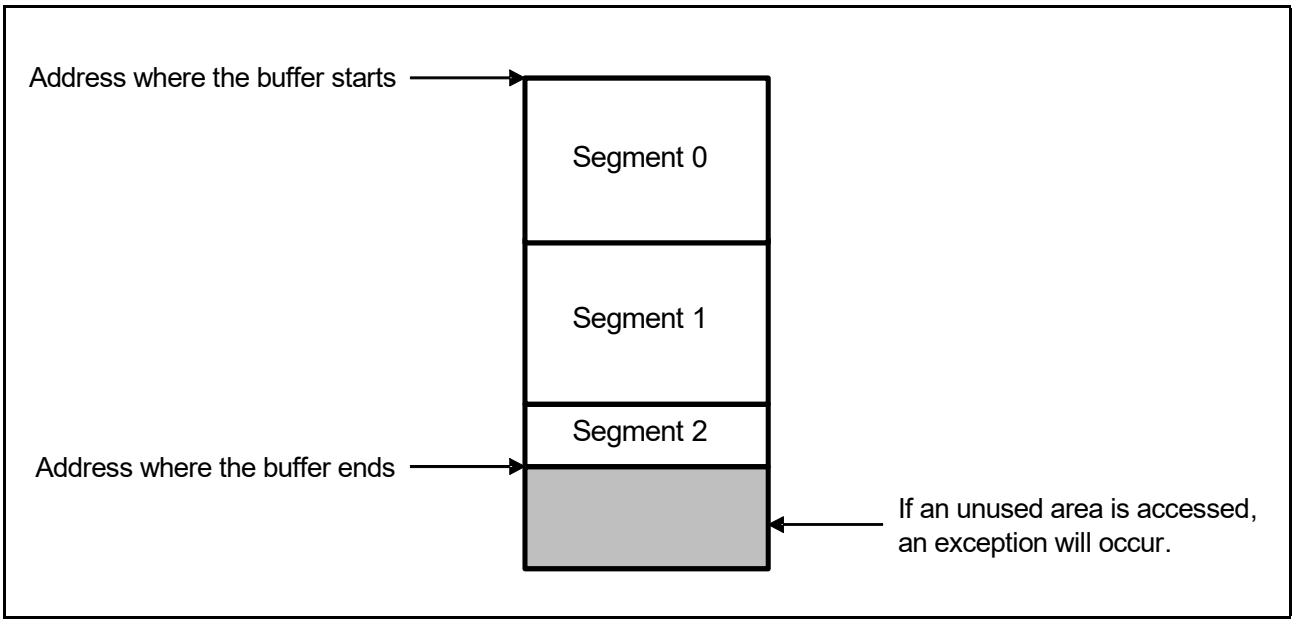


Figure 28.5 Method of Controlling a Buffer

(2) Buffer Control Operation

In this section, short and long buffers are collectively referred to as “buffers”. A short buffer has up to four segments and a long buffer has up to 16 segments.

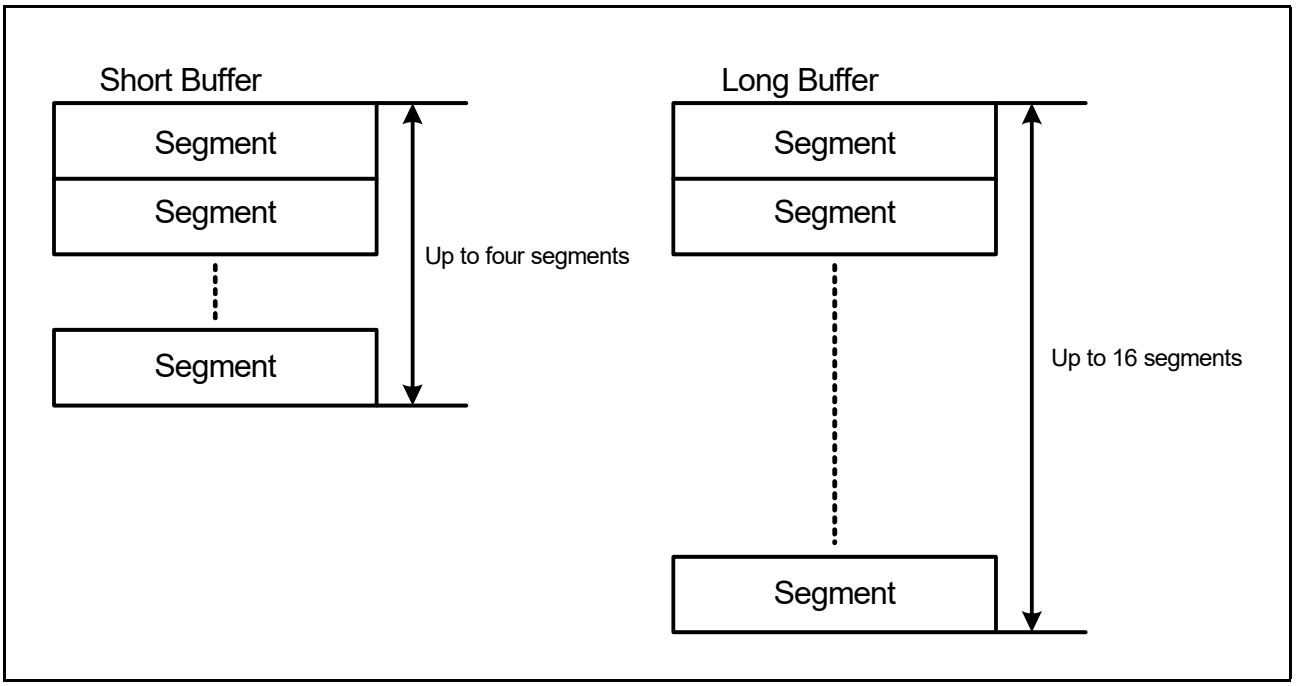

Figure 28.6 Buffer Structure

(a) Acquisition of buffers (HWFNC_ShortBuffer_Get, HWFNC_LongBuffer_Get)

Buffers can be acquired by issuing an HWFNC_ShortBuffer_Get or HWFNC_LongBuffer_Get hardware function call. The size of the buffer is specified in bytes when calling these hardware functions. The number of bytes does not have to reach a segment boundary (128 bytes). The value returned is the address where the buffer starts.
The maximum numbers of short and long buffers that can be acquired are as listed in Table 28.7. Even if fewer short and long buffers are acquired than the maximum, acquisition will fail if the total size of buffers of both sizes exceeds the maximum size imposed by the 128 Kbytes of buffer RAM.

Table 28.7 Number of Buffers that can be Acquired

Buffer Type	Maximum Number of Buffers that can be Acquired	Remarks
Short buffer	128	Up to 512 segments (= 64 Kbytes)
Long buffer	64	Up to 1024 segments (= 128 Kbytes)

The address structure of buffers is shown below. When a buffer is acquired, the function returns the address range from 0C00 0000h to 0FFF FFFFh and 0800 0000h to 0BFF FFFFh for a long buffer and short buffer, respectively.

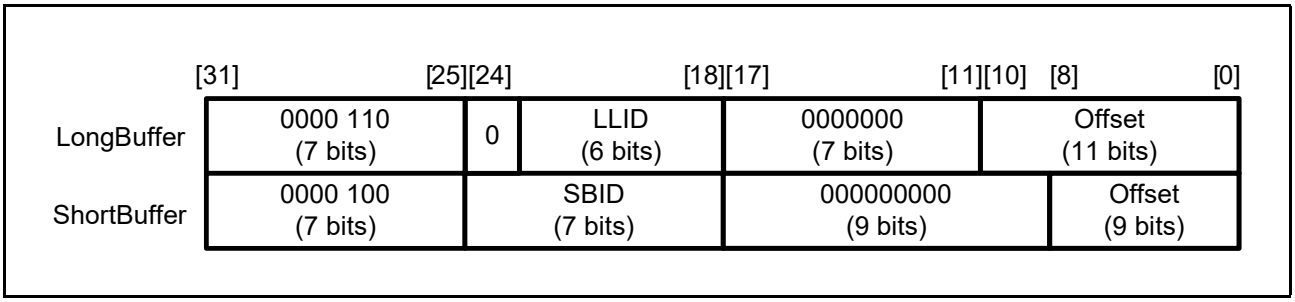

Figure 28.7 Address Structure of Buffers

If a short buffer is acquired, bits [24:18] are given an SBID (short buffer ID), which is used as an identifier for the buffer. The buffer area is allocated with the offset field as 0 to indicate the address where the buffer starts.
If a long buffer is acquired, bits [23:18] are given an LLID (linked long buffer ID), which is used as an identifier for the buffer. The buffer area is allocated with the offset field as 0 to indicate the address where the buffer starts.

(b) Releasing whole area of a buffer (HWFNC_Buffer_Release)

The whole area of an acquired buffer can be released by calling the HWFNC_Buffer_Release hardware function. When calling the hardware function, specify the address where the acquired buffer to be released starts.

(c) Releasing part of a buffer (HWFNC_Buffer_Return)

By calling the HWFNC_Buffer_Return hardware function, desired bytes can be released, starting from the location of a byte within the acquired buffer. This is provided for efficiency in using the space; for example, when a frame is received, another resource can use the area obtained by releasing the area following the end of the received frame data. When executing this system call, the addresses where the buffer and the space to be released start must be given as arguments.

(d) Testing memory and initializing buffers

Since it is not allocated at the time of a reset, buffer RAM is neither writable nor readable in that situation. Accordingly, to test the memory, execute the HWFUNC LongBuffer_Get system call, etc., to secure the full capacity of the buffer RAM and make that memory available for access. This enables subsequent checking of the memory and initializing its contents.

(e) List of Hardware Function Calls

The hardware function calls are listed below and on the following pages.
If an argument of a hardware function call is not correct, the code indicating an invalid system call is returned to the return value register, R0.

Table 28.8 HWFNC_LongBuffer_Get

Name	HWFNC_LongBuffer_Get	
Function	Acquires a long buffer for use in the transmission and reception of frames. A buffer can be acquired with any size in bytes between 1 and 2048. Long buffers are mainly used to hold the data sections of frames. The address where the acquired buffer starts is returned in R1 as the value returned.	
Command register		
SYSC[15:0]	5000h	
Argument registers		
R4	[15:0] Buffer Length	Required buffer length. Unit: bytes. 1 to 2048
	[23:16]	These bits are reserved. Always set these bits to 0.
	[31:24]	Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[1:0] Result	0xb and R0[29] = 1: Success 10b: Invalid system call 11b: The buffer is insufficient
	[28:2]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0] First logical address of the buffer	[31:27] 00001b [26:24] 100b [23:18] LLID [17: 0] 0

Note: For the products incorporating an R-IN Engine, issuing of this command while the hardware real-time OS is prohibited from dispatching does not successfully excecute the hardware function call. In this case, bits 15:0 of the return value register R0 indicates FFE7h.

Table 28.9 HWFNC_ShortBuffer_Get

Name	HWFNC_ShortBuffer_Get	
Function	Acquires a short buffer for use in the transmission and reception of frames. A buffer can be acquired with any size in bytes between 1 and 512. Short buffers are mainly used to hold the header sections of frames, the data sections of ICMP and MAC management frames, etc. The address where the acquired buffer starts is returned in R1 as the value returned.	
Command register		
SYSC[15:0]	5006h	
Argument registers		
R4	[15:0] Buffer Length	Required buffer length. Unit: bytes. 1 to 512
	[31:16]	Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[1:0] Result	0xb: Success 10b: Invalid system call 11b: The buffer is insufficient
	[28:2]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0] First logical address of the buffer	[31:27] 00001b [26:25] 00b [24:18] SBID [17: 0] 0

Table 28.10 HWFNC_Buffer_Release

Name	HWFNC_Buffer_Release	
Function	Releases an acquired long or short buffer.	
Command register		
SYSC[15:0]	5001h	
Argument registers		
R4	[31:0] First logical address of the buffer	First logical address of the buffer to be released The value is returned in R1 following a call of HWFNC_LongBuffer_Get or HWFNC_ShortBuffer_Get.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[1:0] Result	0xb: Success 10b: Invalid system call 11b: A buffer is not definable at the given address.
	[28:2]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

Table 28.11 HWFNC_Buffer_Return

Name	HWFNC_Buffer_Return	
Function	Releases some of the latter half of an acquired short or long buffer. Specifying the location where the address range to be released starts leads to the release of the part of the buffer beginning at that address. The address can be set at byte boundaries. This HWF is for the efficient use of buffer resources, for example when a received frame is short.	
Command register		
SYSC[15:0]	5002h	
Argument registers		
R4	[31:0] First logical address of the buffer	First logical address of the buffer to be released The value is returned in R1 following a call of HWFNC_LongBuffer_Get or HWFNC_ShortBuffer_Get.
R5	[31:0] First logical address of the part for release	First address of the part for release (the part of the buffer at addresses beginning from this address is released)
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[2:0] Result	00xb: Success 010b: Invalid system call 011b: A buffer has not been defined at the address specified by R4. 100b: The buffer at the address specified by R5 has already been released.
	[28:3]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

28.3.1.4 MAC DMA Controller

(1) Functional Overview

The MAC DMA controller is used to transfer data between the buffer RAM and Ethernet MAC. In transmission, the DMAC transfers data to be transmitted from the buffer RAM to the Ethernet MAC; in reception, the DMAC transfers data received by the Ethernet MAC to the buffer RAM. This allows improved throughput for communications.
Figure 28.8 is a block diagram of the MACDMAC in context and the respective interrupt signals.

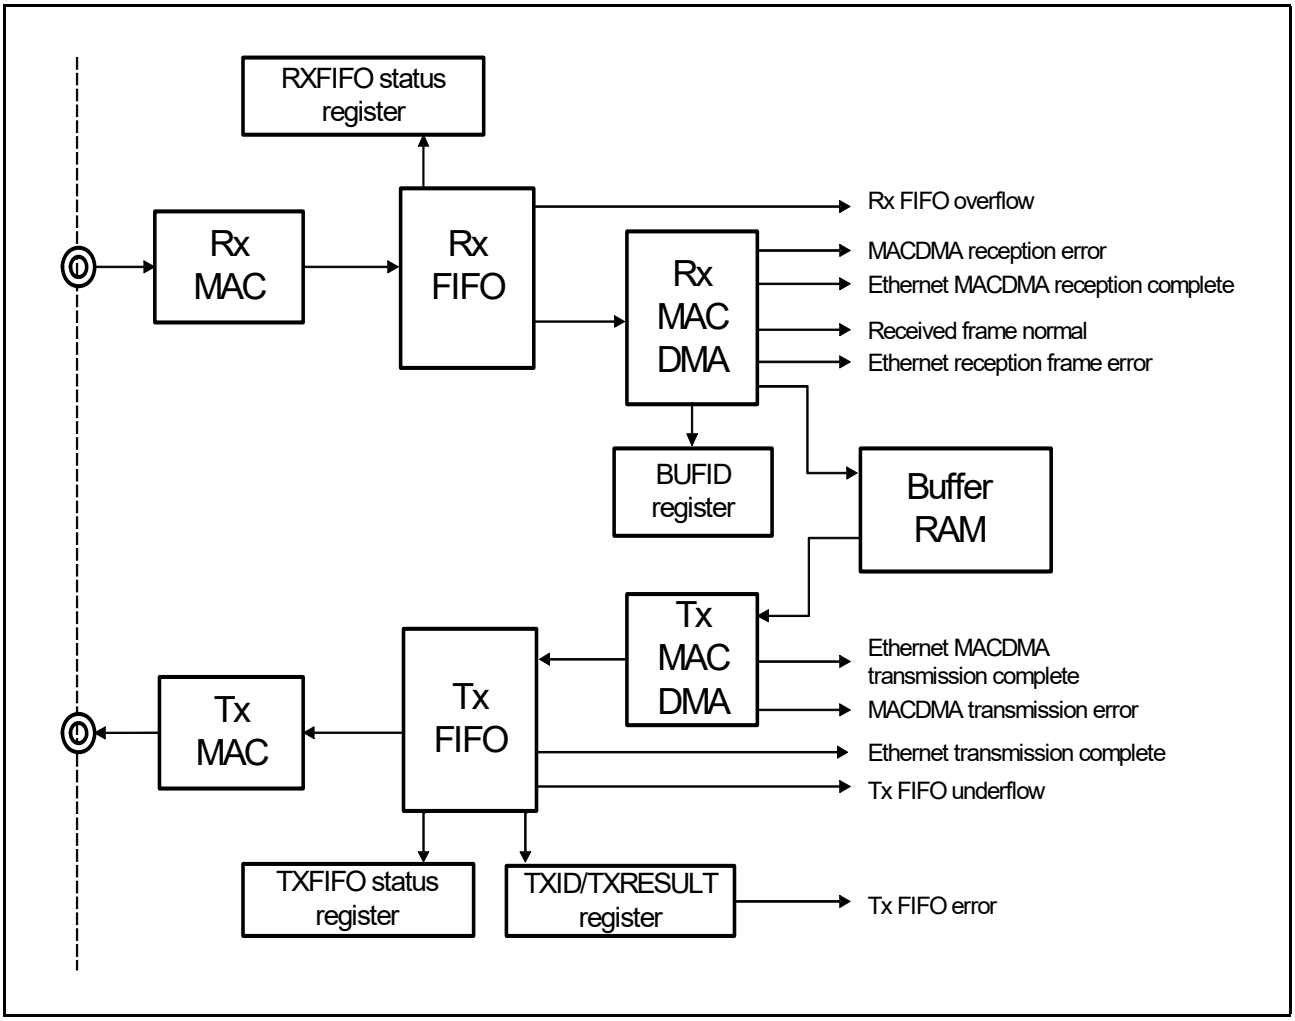

Figure 28.8 Block Diagram of the MACDMAC in context and Interrupt Signals

(2) DMA for the reception MAC

Figure 28.9 shows an outline of processing by the reception MACDMAC. A hardware function call (HWFNC_MACDMA_RX_Enable) must be issued to enable operation of the reception MACDMAC. The reception MACDMAC remains active until HWFNC_MACDMAC_RX_Disable is issued.
While active, the reception MACDMAC constantly monitors the state of the MAC Rx FIFO. When the FIFO holds a received frame, the reception MACDMAC sends a request for the acquisition of a long (2048-byte) buffer to the buffer allocator. Once the long buffer has been acquired, the reception MACDMAC reads data from the MAC Rx FIFO and writes the data sequentially from the start of the acquired long buffer.
After the completion of the full transfer of one frame, the reception MACDMAC writes the number of received words (one word: 32 bits) and the first logical address of the buffer to the BUFID register as information on reception. The information written to the BUFID is described in section 28.2.2.18, Reception Buffer Information Register (BUFID). The BUFID can be read by the CPU and is capable of holding up to 64 pieces of information.

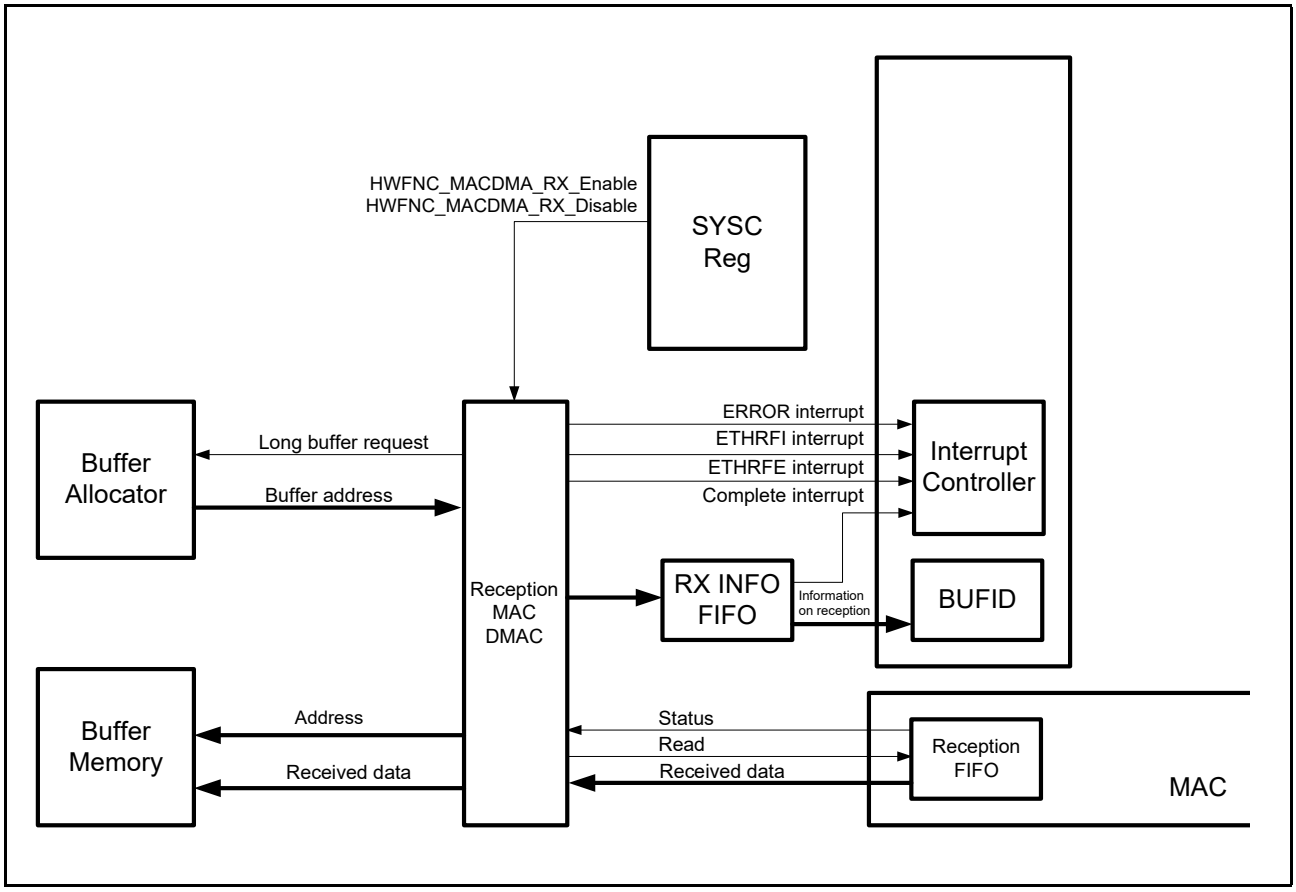

Figure 28.9 Outline of Processing by the Reception MACDMAC

(a) Description of the individual functions of the MAC DMA controller

1-1) Partial release of buffer space

The reception MACDMAC automatically releases an unused area that has no received data in the last buffer to have been acquired (buffer return function call). However, if the unused area is no larger than 128 bytes (one segment), buffer return does not proceed. Buffer return is a function call to release part of the secured buffer area and differs from the buffer release function call that releases the whole area of a secured buffer.

1-2) Full release of the buffer

If the following conditions are satisfied, the reception MACDMAC automatically releases the acquired buffer (calls the buffer release function).

(1) The result of executing the function call for the buffer acquisition request was failure (the buffer has no unused area).
(2) The result of analyzing the information on the received frame is that the received frame is made invalid by HWFNC_MACDMA_RX_Control.
(3) HWFNC_MACDMA_RX_Disable is executed under the following condition:
- The number of received words is not greater than 4092 words

In the above cases 1) and 2), all received frames are discarded and the buffer is released. In case 3), the received frames are not discarded (data resides in the MAC Rx FIFO) but only the release of the buffer is executed, after which the reception MACDMAC is immediately disabled. In any of cases 1), 2), and 3), the result of reception is not written to the BUFID.

1-3) Generation of an error interrupt

An error interrupt is issued in response to detection of the reception MACDMAC having failed to continue operation for reception for some reason or data not having been received correctly. The source of an error interrupt can be checked by executing the hardware function call HWFNC_MACDMA_RX_Errstat.
For details, see (c) List of hardware function calls.

1-4) Generation of reception completed interrupts

If the BUFID has information on the reception of one or more frames, the reception completed interrupt goes to its active level. The reception completed interrupt remains active as long as the BUFID register is not empty; that is, it has information on the reception of one or more frames.
The reception completed interrupt is de-asserted when the BUFID is read and becomes empty.

1-5) Judging whether a received frame is valid or invalid

Judgment of whether a received frame is valid or invalid leads to a received frame normal interrupt (ETHRFI) or Ethernet reception frame error interrupt (ETHRFE) being issued. Each interrupt has more than one source and the generation of interrupts is enabled for all sources in the initial state.

A specified source can be disabled by executing HWFNC_MACDMA_RX_Control. The frame corresponding to the factor that caused disabling is discarded by the whole-buffer release function.

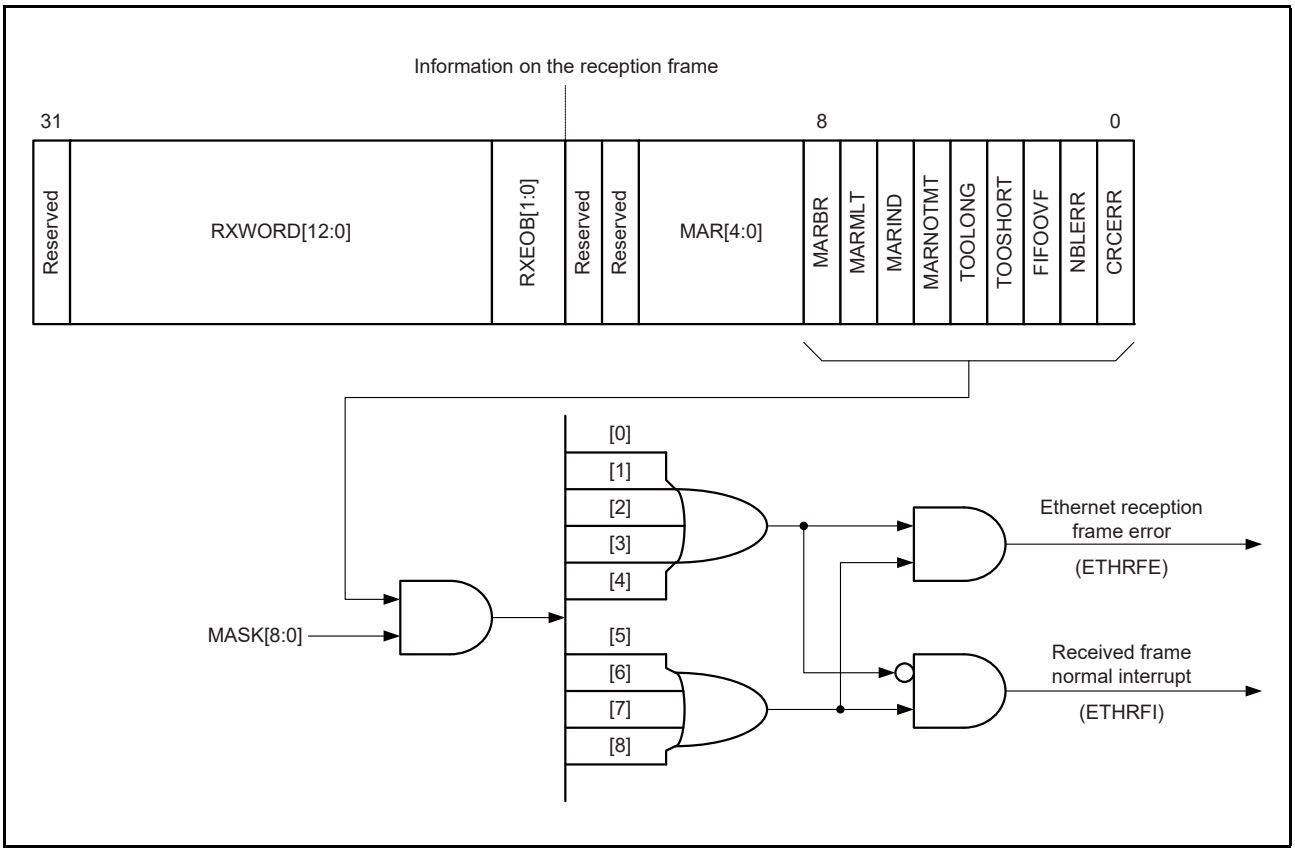

Figure 28.10 Conceptual Diagram of Judging Whether a Received Frame is Valid or Invalid

(b) Usage

2-1) Procedure for reading and releasing buffers

A buffer which has received data must always be released after use. An example of the procedure is given below.

[Example of reading and releasing a buffer]

(1) Read the BUFID register.
(2) Shift the bits [27:16] read from BUFID 16 bits to the right to obtain the number of received words.
(3) The bits [15:0] read from the BUFID are bits [26:11] of the address where the acquired buffer starts.
The individual bits of the address where the acquired buffer starts are configured as follows.
[31:27]: 00001b
[26:18]: Equivalent to bits [15:7] in the BUFID
[17:11]: Equivalent to bits [6:0] in the BUFID
[10:0]: Always 0
(4) After using the buffer, specify the start address as an argument and issue the buffer release function call to release the buffer.

2-2) Procedure for processing in response to an error interrupt

An example of the recommended procedure for processing in response to an error interrupt is given below. The value of R0[7:0] obtained by the HWFNC_MACDMA_RX_ERRSTAT function call is hereafter called bits [7:0] of the result of reading the error state.

(1) Bit [3] of the result of reading the error state = 1 (a function call to forcibly end MACDMA Rx has been executed)
(a) If bit [0] of the result of reading the error state = 1, proceed to step 3).
(b) If bits [2:0] of the result of reading the error state have the value 4 or 0, the interrupt source is the forced termination of reception while it was in progress and this does not represent a problem. Since the received frames are all discarded and the information is not written to the BUFID, nothing is done, so simply return to normal processing. The reception MAC FIFO may still have frame data that was received, but in such cases, the hardware automatically discards that data before the next round of reception starts.

(2) Bit [2] of the result of reading the error state = 1 (the size of the frame is at least 4096 words)
(a) If bit [0] of the result of reading the error state = 1, proceed to step 3).
(b) Received data are all stored. The start address is obtained by reading the BUFID.
(c) Buffers that are no longer required are released according to the method given as [Example 2] in 2-1) Procedure for reading and releasing buffers.
(d) Returns to normal processing.

(3) Bit [0] of the result of reading the error state = 1 (the remaining capacity of the buffer is insufficient)
(a) If bit [2] of the result of reading the error state = 1 (the size of the received frame is at least 4096 words) is satisfied at the same time, the buffer capacity is considered temporarily insufficient, so nothing is done.
(b) If the remaining capacity of the buffer is considered insufficient, the buffer is released to provide space.
(c) Return to normal processing. Note that received frames may have been lost during this period.

(c) List of hardware function calls

The table below lists the hardware function calls.
If an argument of a hardware function call is invalid, an invalid system call error code is returned in the return value register, R0.
If an error occurs while the hardware function call is running, an interrupt is generated.

Table 28.12 HWFNC_MACDMA_RX_Enable

Name	HWFNC_MACDMA_RX_Enable	
Function	Enables DMA for the reception MAC, that is, the transfer of data to the buffer memory from the MAC. As long as the reception DMAC is enabled, transfer starts automatically whenever the FIFO buffer within the MAC collects received frames. Since the DMAC executes Get Buffer at this time, the buffer memory is automatically acquired.	
Command register		
SYSC[15:0]	5101h	
Argument registers		
R4	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[0] Result	0: Success 1: Invalid system call*1
	[28:1]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

Note 1. If this hardware function is called while it is not disabled (this function call is already being executed) or this hardware function is called while a buffer return or release operation is in progress after reception has been suspended, the result is an invalid system call.

Note: The number of bytes to be transferred at a time is from 4 to 2048 bytes. Exceeding this range leads to the generation of an exception.

Table 28.13 HWFNC_MACDMA_RX_Disable

Name	HWFNC_MACDMA_RX_Disable		
Function	Disables DMA for the reception MAC. When forced reset is enabled, the data being received are discarded and information on reception is not stored in the BUFID register. At this time, the buffer is automatically released. When forced reset is disabled, the buffer is not automatically released.		
Command register			
SYSC[15:0]	5102h		
Argument registers			
R4	[0] Forced reset		0: This function is disabled while reception is in progress. 1: If the reception DMAC is enabled, it is disabled even if reception is in progress (the reception DMAC is forcibly reset). Nothing is done if the reception DMAC is already disabled.
	[31:1]		Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]		Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]		Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]		Note: These bits are not used in this function call. The setting will be ignored.
Return value registers			
R0	[1:0] Result	When R4[0] = 0	00b: Success 01b: Invalid system call (the buffer is in use or reception is suspended) 10b: The function cannot be disabled since reception is in progress. 11b: The function has already been disabled.
		When R4[0] = 1	00b: Success 01b: Invalid system call (the buffer is in use or reception is suspended)
	[28:2]		These bits are reserved. The value is always 0.
	[29] Complete		0: Hardware function call not completed 1: Hardware function call completed
	[31:30]		These bits are reserved. The value is always 0.
R1	[31:0]		These bits are reserved. The value is always 0.

Table 28.14 HWFNC_MACDMA_RX_Control

Name	HWFNC_MACDMA_RX_Control	
Function	Controls enabling or disabling of the interrupt source corresponding to bits [8:0] of the received frame information.	
Command register		
SYSC[15:0]	510Bh	
Argument registers		
R4	[8:0] Interrupt source	Controls enabling or disabling of the interrupt source corresponding to each bit.*1 0: Interrupts disabled 1: Interrupts enabled (initial value)
	[31:9]	Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[0] Result	0: Success 1: Invalid system call
	[28:1]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

Note 1. For details on the interrupt sources, see Figure 28.10, Conceptual Diagram of Judging Whether a Received Frame is Valid or Invalid.

Table 28.15 HWFNC_MACDMA_RX_Errstat

Name	HWFNC_MACDMA_RX_Errstat	
Function	Obtains error interrupt sources for the reception MACDMAC.	
Command register		
SYSC[15:0]	510Dh	
Argument registers		
R4	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[3:0] Result	[0]: Buffer Get fails [1]: Always 0 [2]: Received data has exceeded 4096 words (16 Kbytes). [3]: HWFNC_MACDMA_Rx_Disable is issued when forced reset is enabled.
	[28:4]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

(3) DMA for the transmission MAC

(a) Usage

The transmission MACDMAC uses descriptors. The descriptors are located in the buffer memory. That is, the software must acquire a buffer for the descriptor by issuing using a hardware function call before DMA can be set up. This buffer can be long or short. One buffer can hold multiple descriptors.

A transmission descriptor is shown in detail in Figure 28.11, Transmission Descriptor. Note that a descriptor must start on a 64-bit boundary. If it is not on a 64-bit boundary, the result of trying to use it is in an invalid system call and the error value is stored in the return value register R0.
A descriptor is formed in a succession of a 32-bit address and a 32-bit transfer byte count. Address FFFF FFFFh indicates the end of a descriptor. The address field of a descriptor indicates the transmission start address, and the byte count indicates the number of bytes to be transmitted from that address. The DMAC reads the first pair of address and byte count in a descriptor, and then writes the specified data to transmission MAC FIFO. After that, the DMAC reads the next pair of address and byte count, and then writes the specified data to the transmission MAC FIFO. The DMAC continues this processing until it reads the end of the descriptor (FFFF FFFFh).
Source start addresses in the descriptor can be specified in units of bytes. The size of data to be transmitted can be specified in units of bytes. If the data writing point in the transmission FIFO is not at a word boundary, the DMAC automatically inserts padding.
The transmission MACDMAC starts when a function call HWFNC_MACDMA_TX_Start is issued. When this function call is issued, the start address of the transmit descriptor must be specified in the argument register R4.
Note that if the address field is not FFFF FFFFh and 0 is specified in the descriptor byte count field, the DMAC ignores the address field and does not perform transmission. In this case, DMA reads the next descriptor.
If the value of an address field is incorrect (for example, the address is outside the buffer area) or the number of transfer bytes is incorrect (for example, continued access causes a buffer area overflow), a MACDMA transmission error interrupt occurs.

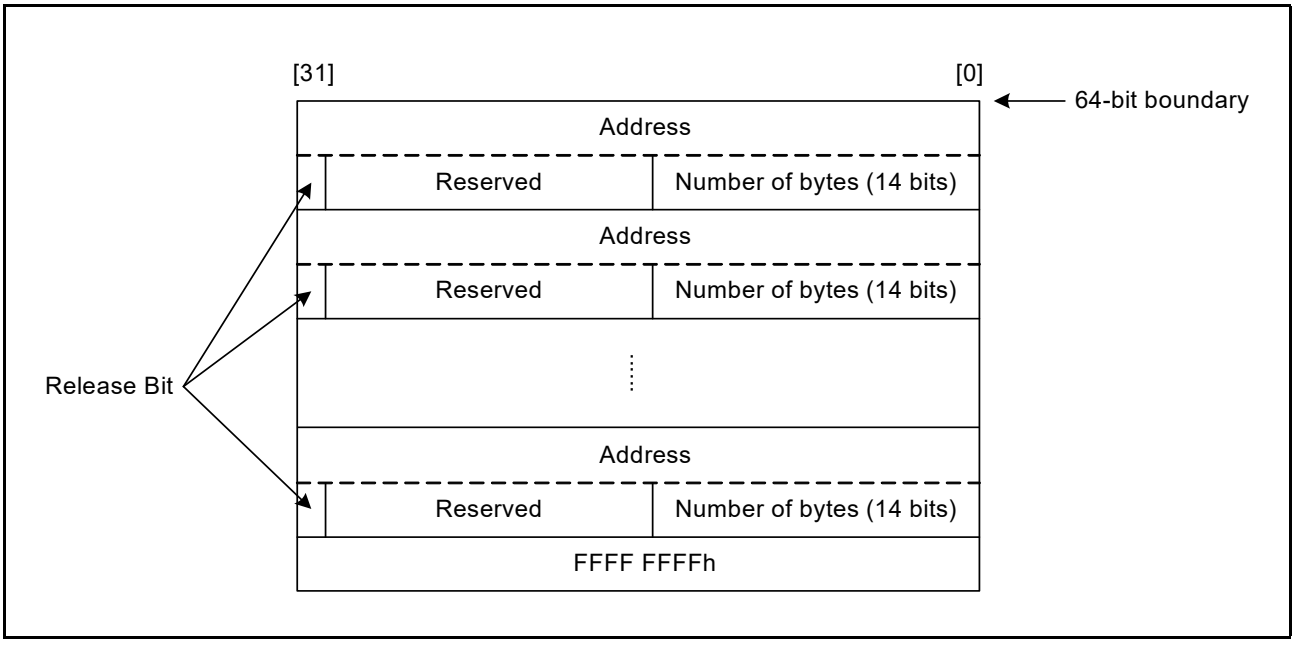

Figure 28.11 Transmission Descriptor

(b) Automatic release of the buffer

If the release bit of the transmission descriptor is 0, no buffer is released. If the release bit is 1, the transmission MACDMAC uses a buffer release function call to automatically release a buffer from the buffer area whose start address is indicated by the relevant descriptor after completion of transmission.

(c) Example of operation

Figure 28.12 shows an example of operation for transmission by combining multiple buffers for use by the transmission MACDMAC.

Two independent buffers of buffer 1 and buffer 2 are combined for transmission by the transmission MACDMA by allocating transmission descriptors at the consecutive 64-bit boundary addresses. The area labelled “Unused” means that the data end before the end of the segment (that is, it does not end at the 128-byte boundary). In transfer, the address where the data in a buffer start need not necessarily be the start of the buffer.

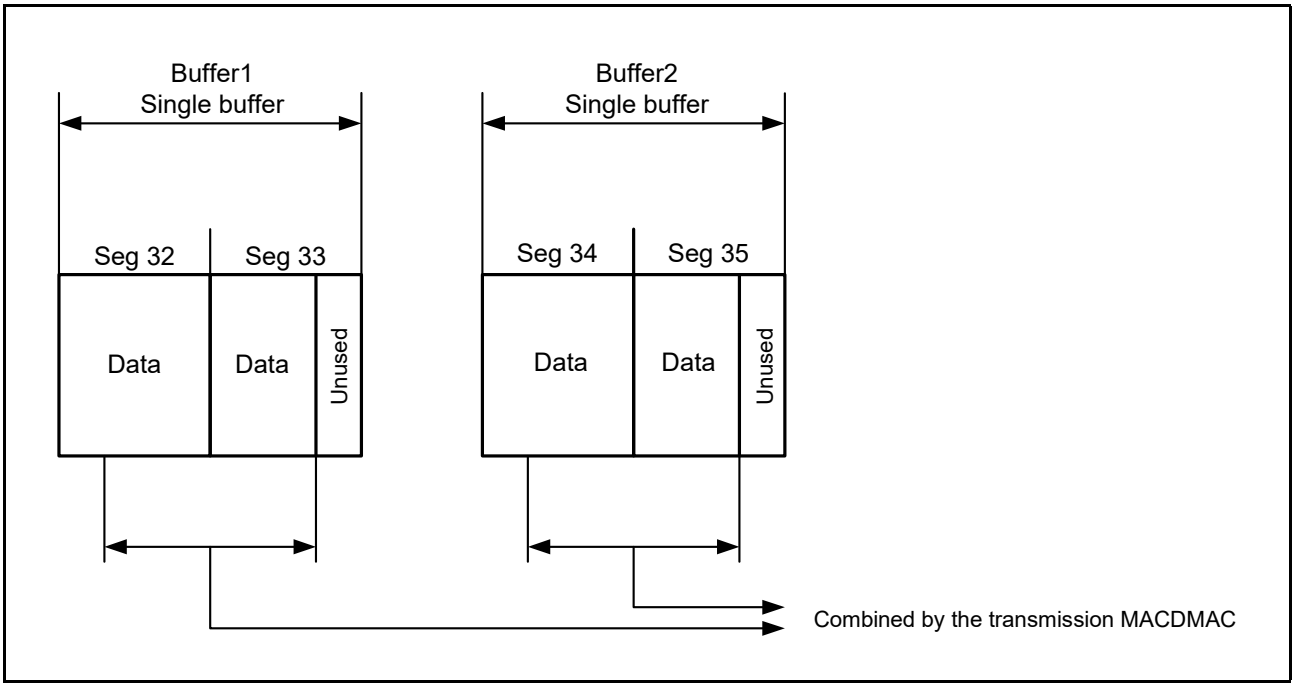

Figure 28.12 Example of Transmission as One Frame by Combining Multiple Buffers

(d) List of hardware function calls

The table below lists the hardware function calls.
If an argument of a hardware function call is invalid, an invalid system call error code is returned in the return value register, R0.
If an error occurs while the hardware function call is running, an interrupt is generated.

Table 28.16 HWFNC_MACDMA_TX_Start

Name	HWFNC_MACDMA_TX_Start	
Function	Transfers data from the buffer memory to the Ethernet MAC. The address where the transmission descriptor starts is set in R4. When transfer ends, an interrupt is generated. The number of bytes to be transferred at a time is from 1 to 2048 bytes.	
Command register		
SYSC[15:0]	5100h	
Argument registers		
R4	[31:0] Address of the descriptor	Address of the transmission descriptor
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[6:0]	These bits are reserved. Always set these bits to 0.
	[31:7]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[0] Result	0: Success 1: Invalid system call
	[28:1]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

Table 28.17 HWFNC_MACDMA_TX_Errstat

Name	HWFNC_MACDMA_TX_Errstat	
Function	Obtains error interrupt sources for the transmission MACDMAC	
Command register		
SYSC[15:0]	510Ch	
Argument registers		
R4	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R5	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R6	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[1:0] Result	[0]: 0: Success 1: Memory access violation • Access to a buffer that is not acquired • The number of bytes for transfer is invalid. • The address where the descriptor starts is not on a 64-bit boundary. [1]: 0: Success 1: Memory access timeout • The address where the transmission descriptor starts turns to be an end value (FFFF FFFFh). • Releasing the buffer with automatic buffer release failed.
	[28:2]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0]	These bits are reserved. The value is always 0.

28.3.1.5 Buffer RAM DMA Controller

(1) Functional Overview

The buffer RAM DMA controller transfers data between the buffer RAM and data RAM. It is used to transfer data for transmission by the MAC DMAC to the buffer and to transfer data received by the MAC DMAC to the data RAM.

(2) DMA transfer

Control of the buffer RAM DMA controller for each form of transfer is described below.

(a) Transfer between the buffer RAM and the data RAM

Calling the HWFNC_Direct_Memory_Transfer hardware function starts transfer between the buffer RAM and data RAM.
After the command has been issued, check that issuing the hardware function call has been completed by reading bit 29 in the R0 register. The DMA transfer has been completed at this point.

(b) Replacing data in the buffer RAM or data RAM

By executing the hardware function HWFNC_Direct_Memory_Replace, an area in the buffer RAM or data RAM can be overwritten by a desired 32-bit data pattern.
The start and end of the area to be written must be on 128-bit boundaries so the amount of data written must be a multiple of 128 bits.
After the command has been issued, check that issuing the hardware function call has been completed by reading bit 29 in the R0 register. The writing of the data pattern has been completed at this point.

(c) List of hardware function calls

The table below lists the hardware function calls.
If an argument of a hardware function call is invalid, an invalid system call error code is returned in the return value register, R0.
Access to an access-prohibited area (an area other than the buffer RAM, etc.) while the hardware function call is running leads to the return of an exception code in the return value register R0.

Table 28.18 HWFNC_Direct_Memory_Transfer

Name	HWFNC_Direct_Memory_Transfer	
Function	Transfers data from the data RAM to the buffer RAM or from the buffer RAM to the data RAM.	
Command register		
SYSC[15:0]	5211h	
Argument registers		
R4	[31:0] Address where the source area for transfer starts	Specifies the address where the source area for transfer starts.
R5	[31:0] Address where the destination area for transfer starts	Specifies the address where the destination area for transfer starts.
R6	[31:0] Number of bytes for transfer	Specifies the number of bytes for transfer.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[1:0] Result	00b: Success 01b: Invalid system call (transfer from the buffer RAM to the buffer RAM has been specified) 10b: An exception has occurred
	[28:2]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0] Address where the exception occurred	When an exception has occurred, this is the address where it occurred. In other cases, all 0s.

Table 28.19 HWFNC_Direct_Memory_Replace

Name	HWFNC_Direct_Memory_Replace	
Function	Replaces the specified memory area in the data RAM or buffer RAM with a defined data pattern. The number of words to be written must be at least four (a word is 32 bits).	
Command register		
SYSC[15:0]	5212h	
Argument registers		
R4	[31:0] Pattern	Specifies the data pattern for writing.
R5	[31:0] Start address	Specifies the address where the destination area for writing starts.
R6	[31:0] Number of words	Specifies the number of words to be written.
R7	[31:0]	Note: These bits are not used in this function call. The setting will be ignored.
Return value registers		
R0	[1:0] Result	00b: Success 01b: Invalid system call The set address was specified in byte units or the setting for the number of words to be transferred is three or fewer. 10b: An exception has occurred.
	[28:2]	These bits are reserved. The value is always 0.
	[29] Complete	0: Hardware function call not completed 1: Hardware function call completed
	[31:30]	These bits are reserved. The value is always 0.
R1	[31:0] Address where the exception occurred	When an exception has occurred, this is the address where it occurred. In other cases, all 0s.

28.3.2 Interrupts

The interrupts that the Ethernet MAC generates are described below.

Table 28.20 Interrupts related to Operations for Transmission

Interrupt Name	Symbol	Conditions for Asserting and De-asserting Interrupts
TX FIFO underflow	ETHTFIU	This interrupt is generated when the transmission size specified in the descriptor and transmission frame control information differ. At this time, transmission does not proceed. Modify the settings of the descriptor or the transmission frame information for retransmission. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
TX FIFO error interrupt	ETHTFIE	This interrupt is generated when information is further updated while the GMAC_TXID/GMAC_TXRESULT register is holding the maximum number of items of information (four). Take care, since the oldest of the retained information will have been overwritten when this error occurs. Reading the GMAC_TXID/GMAC_TXRESULT register repeatedly until the value of the GMAC_TXFIFO.TRBFR bit becomes 0 leads to clearing of the retained information and restoring normal operation.
MACDMA transmission error interrupt	ETHDTIE	This interrupt is generated when an error occurs while the transmission MAC DMA is operating. There are several error sources and HWFNC_MACDMA_TX_Errstat is used to obtain the error source. Modify the settings of the transmission descriptor for retransmission. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
Ethernet MACDMA transmission complete	ETHDMAIT	This interrupt is generated when DMA transfer from the buffer RAM to the transmission MAC FIFO is completed. At this time, DMA transfer has been completed but operations for communications by the MAC are not. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
Ethernet transmission complete interrupt	ETHIT	This interrupt occurs when operations for communications by the transmission MAC are completed. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.

Table 28.21 Interrupts related to Operations for Reception

Interrupt Name	Symbol	Conditions for Asserting and De-asserting Interrupts
Ethernet MACDMA reception complete	ETHDMAIR	This interrupt is generated when operations by the reception MACDMAC end normally. It remains active until the BUFID register becomes empty of information on reception. The interrupt source is de-asserted when the BUFID is read and becomes empty.
MACDMA reception error interrupt	ETHDRIE	This interrupt indicates that an error has occurred while the reception MACDMAC was operating. There is more than one source for this error, and the precise source is obtained by issuing HWFNC_MACDMA_RX_Errstat. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
Received frame normal interrupt	ETHRFI	This interrupt is generated when operations by the reception MACDMAC end normally and the received frame is normal. The interrupt source can be specified by referring to information on the received frame. It remains active until the BUFID register becomes empty of information on reception. The interrupt source is de-asserted when the BUFID is read and becomes empty.
Ethernet reception frame error	ETHRFE	This interrupt is generated when operations by the reception MACDMAC end normally and the received frame has an error. The interrupt source can be specified by referring to information on the received frame. It remains active until the BUFID register becomes empty of information on reception. The interrupt source is de-asserted when the BUFID is read and becomes empty.
RX FIFO overflow	ETHRFIV	This interrupt is generated when data are received while the buffer does not have enough space, so the Rx FIFO overflows. When this error occurs, received data may already have been discarded. Restore the system to the state where reception is possible by releasing the buffer, etc. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.

Table 28.22 Interrupts related to Other Operations

Interrupt Name	Symbol	Conditions for Asserting and De-asserting Interrupts
Ethernet MII management access complete interrupt	ETHMMAI	This interrupt is generated when reading from or writing to the MII management bus is completed. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
Ethernet pause packet transmission complete	ETHPPIT	This interrupt is generated when the transmission of a pause packet is completed. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
LPI start notification interrupt from MII	ETHLPIST	This interrupt is generated when a link partner notifies the Ethernet MAC of an LPI request. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.
LPI end notification interrupt from MII	ETHLPIEND	This interrupt is generated when a link partner de-asserts an LPI request. Since this interrupt is generated as a pulse, de-asserting the interrupt source is not required.

28.3.3 Ethernet Frame Transmission Function

This section describes transmission of Ethernet frames. For Ethernet MAC, Ethernet frames are transmitted in the following sequence:

1. Initial setup is performed. (Section 28.3.1.1)
2. A send buffer is obtained. (Section 28.3.3.1)
3. Transmission frame control information is created. (Section 28.3.3.2(1))
4. Ethernet frame data is created. (Section 28.3.3.2(2))
5. Transmit descriptors are created. (Section 28.3.3.3)
6. A DMA wake-up command is executed. (Section 28.3.3.4)
7. DMA transfer is performed according to transmit descriptors.
8. Ethernet transmission is started by MAC according to the transmission frame control information included in the transmit data.
9. A transmission completion interrupt occurs.
10. Post-transmission processing, including the status check, is performed. (Section 28.3.3.5)
11. The send buffer is released. (Optional)

The above steps are described in the following sections.

28.3.3.1 Obtaining a transmission buffer

Set hardware function call registers as shown below to obtain a transmission buffer.

Register	Setting Value
SYSC	5000h
R4	Size of the memory block to be secured (1 to 2048 bytes).
R5	0 (Unused)
R6	0 (Unused)
R7	0 (Unused)

The hardware function returns a value as follows:

Register	Setting Value
R0	0xb and R0[29] = 1: Success 10b: Invalid system call 11b: The buffer is insufficient
R1	Start address of the allocated memory block

28.3.3.2 Creating transmit data

Figure 28.13 shows the format of transmit data. The start address of this frame is specified by using transmit descriptors.
For Ethernet MAC, the size and other items for controlling transmit frames are specified by prefixing 64-bit transmission frame control information to the ordinary Ethernet frame data.

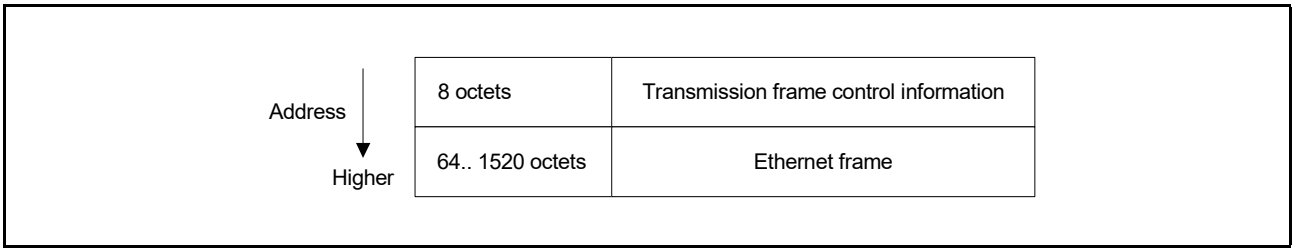

Figure 28.13 Format of Transmit Data

Note: Make sure that the transmission data is in this format.

(1) Transmission frame control information

The fields of the transmission frame control information are described below.

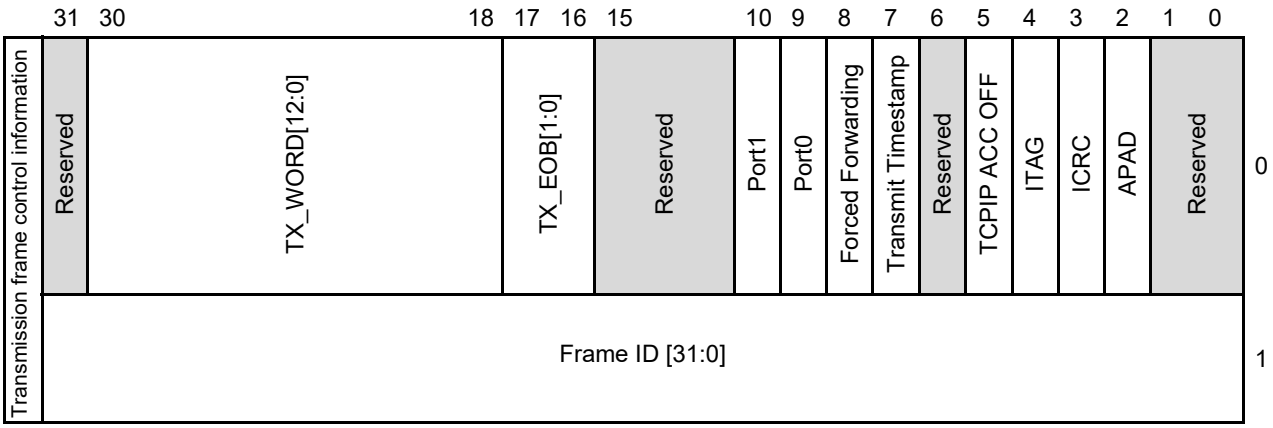

Figure 28.14 Transmission Frame Control Information

Note: Any value is allowed for the Reserved bit.

Item	Explanation
TX_WORD[12:0]	Specifies the number of words in the Ethernet frame to be transmitted (a word is 32 bits). The number of valid bytes in the last word is specified by using TX_EOB[1:0].
TX_EOB[1:0]	Indicates the extent of valid octets in the last 1 word of this frame. 00: 1 byte is valid. 01: 2 bytes are valid. 10: 3 bytes are valid. 11: 4 bytes are valid.
Port 1*1	The Forced Forwarding function of the Ethernet switch is permitted for Port 1.
Port 0*1	The Forced Forwarding function of the Ethernet switch is permitted for Port 0.
Forced Forwarding*1	The Forced Forwarding function of the Ethernet switch is enabled. If this function is enabled, frames are output from the specified port regardless of the filter settings of the switch.
Transmit Timestamp*1	The timestamp function for transmit frames is enabled when an Ethernet switch is used.
TCPIP ACC OFF*2	1: Disables the TCPIP accelerator. 0: Enables the TCPIP accelerator.
ITAG	Indicates that this frame includes a VLAN TAG.
ICRC	The CRC has already been attached to the frame. When the setting of this bit is 1, APAD is invalid.
APAD	APAD selects the automatic inclusion of padding if the frame length is less than 64 octets.
Frame ID[31:0]	Specifies a frame identifier.

Note 1. This item is valid only when insertion of the management tag is permitted for the Ethernet switch management TAG control register (ETHSWMTC). If no management tag is inserted, this field is invalid. For details on the Ethernet switch, see section 29, Ethernet Switch.

Note 2. Disable the TCPIP accelerator when a frame of either of the following types is to be transmitted.
- An IPv6 frame which does not include a UDP or TCP packet.
- An IEEE802.3 + IEEE802.2 (LLC) frame

If TX_LENGH[14:0] (15 bits) consists of TX_WORD[12:0] and TX_EOB[1:0], TX_LENGH[14:0] can be calculated from the Ethernet frame transmission size (in bytes) by using the following expression:
TCPIPACC Pad Size is 2 when the transmission TCPIP accelerator is enabled (GMAC_ACC.TTCPIPEN = 1), and 0 when disabled.

TX_LENGH [14:0] = (TX Frame Size – TCPIPACC Pad Size + 3) (bytes)

(2) Ethernet frame

The fields (data format) of Ethernet frames for transmission are listed in the table below.

Item	Explanation
Destination MAC Address	MAC address of the transmission destination
Source MAC Address	MAC address of the transmission source
Type/Length	Ethernet type or length
VLAN Tag	Tag protocol identifier: Used when VLAN tag is included.
VLAN Info	Tag control information: Used when VLAN tag is included.
Frame Payload	Payload

(a) When the transmission TCPIP accelerator is enabled

When the transmission TCPIP accelerator is enabled (GMAC_ACC.TTCPIPEN = 1), two bytes of padding must be inserted between the type/length field and the payload.

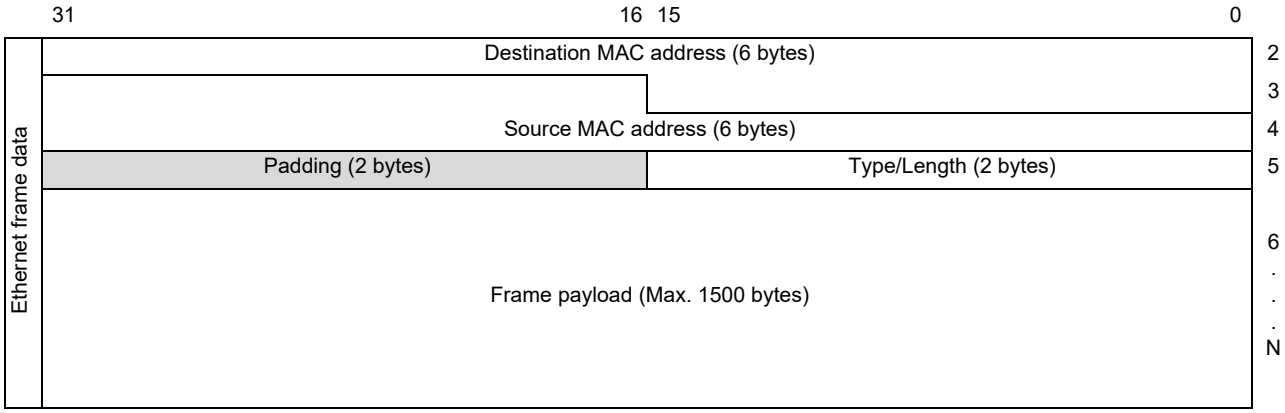

Figure 28.15 Format for Transmission Data (TCPIP Accelerator Enabled, VLAN Tag not Included)

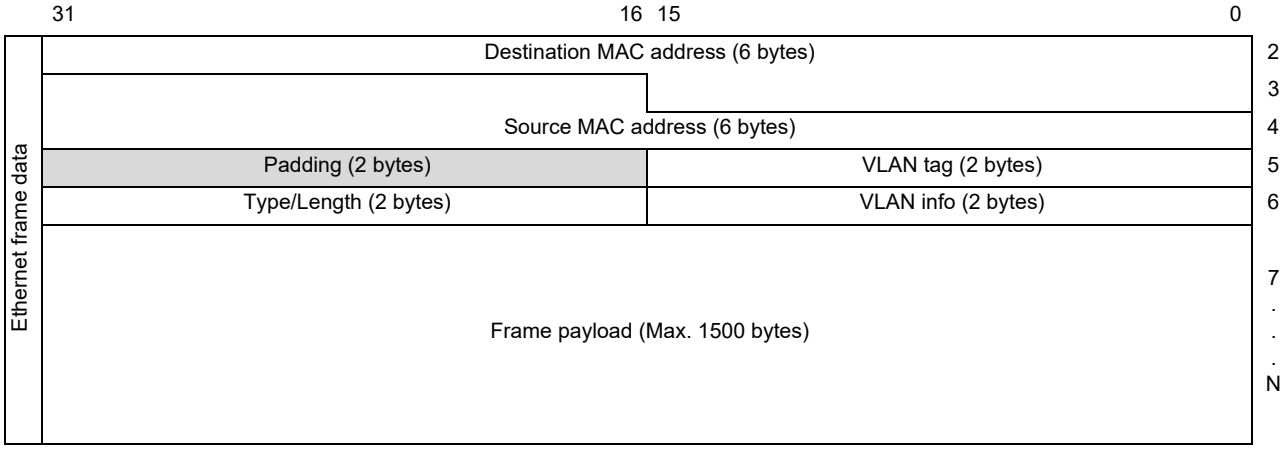

Figure 28.16 Format for Transmission Data (TCPIP Accelerator Enabled, VLAN Tag Included)

Note: The padding field (2 bytes) can have any value. The padding (two bytes) is not included in the size to be specified for the Ethernet frame (TX_WORD[12:0] and TX_EOB[1:0]).

(b) When the transmission TCPIP accelerator is disabled

The following shows the Ethernet frame when the transmission TCPIP accelerator is disabled (GMAC_ACC.TTCPIPEN = 0).

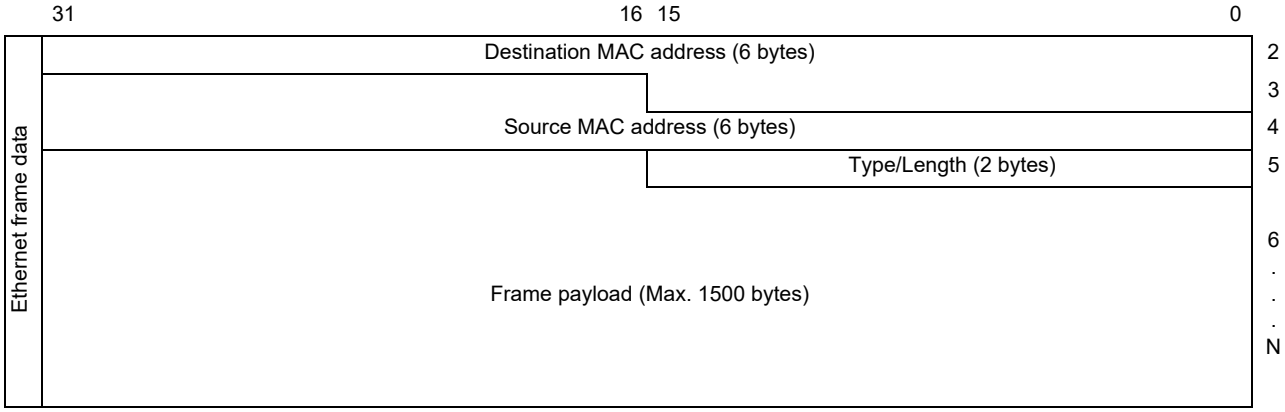

Figure 28.17 Format for Transmission Data (TCPIP Accelerator Disabled, VLAN Tag not Included)

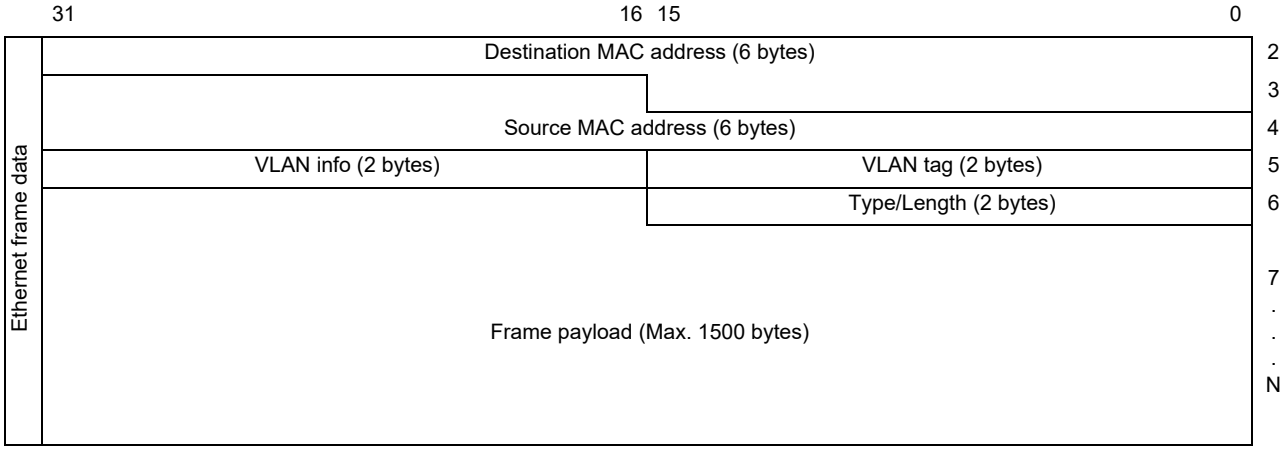

Figure 28.18 Format for Transmission Data (TCPIP Accelerator Disabled, VLAN Tag Included)

28.3.3.3 Creating transmit descriptors

A descriptor for use with the DMA controller for the TX MAC needs to be created. Activating the TX DMAC after creating a descriptor starts transmission. For details on the transmit descriptor, see Section 28.3.1.4 (3) DMA for the transmission MAC.

28.3.3.4 Starting transmission

When hardware function call registers are set as shown below, the transmission DMAC is started. DMA then starts transmission.

Register	Setting Value
SYSC	5100h
R4	Transmit descriptor address
R5	0 (Unused)
R6	0 (Unused)
R7	Set 0.

The hardware function returns a value as follows:

Register	Setting Value
R0	0: Success 1: Error (invalid call)
R1	Fixed to 0

28.3.3.5 Completing transmission

An Ethernet MACDMA transmission completed interrupt is generated on completion of the DMA transfer. An Ethernet transmission completed interrupt is generated on completion of transmission from the MAC.
If the transmission buffer that has already been secured is reused for the next transmission, you do not need to obtain another transmission buffer.

28.3.4 Ethernet Frame Reception Function

This section describes reception of Ethernet frames. For Ethernet MAC, Ethernet frames are received in the following sequence:

1. Initial setup is performed. (Section 28.3.4.1)
2. The reception MAC is enabled. (Section 28.3.4.2)
3. The reception DMAC is started. (Section 28.3.4.3)
4. Frames are received and a buffer is obtained. (Section 28.3.4.4)
5. A reception completion interrupt occurs.
6. Reception buffer information is obtained. (Section 28.3.4.5)
7. Frame status is checked. (Section 28.3.4.6(1))
8. Ethernet frame data is obtained. (Section 28.3.4.6(2))
9. The reception buffer is released.

28.3.4.1 Initial setup

MAC is reset and each register is set up in the same way as in initial setup for the Ethernet frame transmission function.

28.3.4.2 Enabling the reception MAC

Set the reception enable register (GMAC_RXMAC_ENA) to 1 to enable the reception MAC.

28.3.4.3 Starting the reception DMAC

Set hardware function call registers as shown below to start the receive DMA controller.

Register	Setting Value
SYSC	5101h
R4	0 (Unused)
R5	0 (Unused)
R6	0 (Unused)
R7	Set 0.

The hardware function returns a value as follows:

Register	Setting Value
R0	0: Success 1: Error (invalid call)
R1	Fixed to 0

28.3.4.4 Receiving frames and obtaining a buffer

When frame reception occurs, the reception buffer is automatically obtained by hardware.

28.3.4.5 Obtaining reception buffer information

After completion of reception is detected by a reception completion interrupt or another means, the reception buffer information register (BUFID) is read to obtain address and size of the buffer that stores receive data.
After the address information is obtained, the buffer that stores data is referenced to obtain the received frame information and Ethernet frame data. For the format of received data, see the format of received data in the next section.

28.3.4.6 Format of received data

In the reception of frames by the Ethernet MAC, 64 bits of received frame information will be appended after the frame data. This information indicates the state of reception: size of the Ethernet frame, errors, and so on.
Since the received frame information starts on a 64-bit boundary, the amount of padding following the Ethernet frame will vary with the frame size.

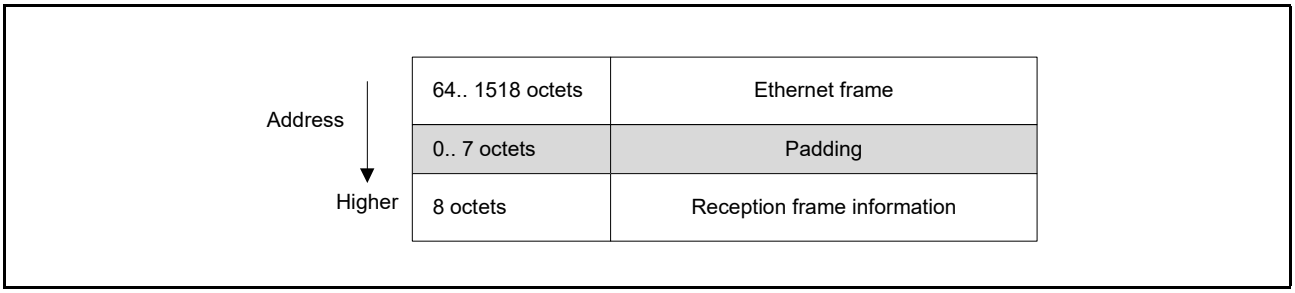

Figure 28.19 Format of Received Data

(1) Received frame information

The fields of the received frame information are described below.

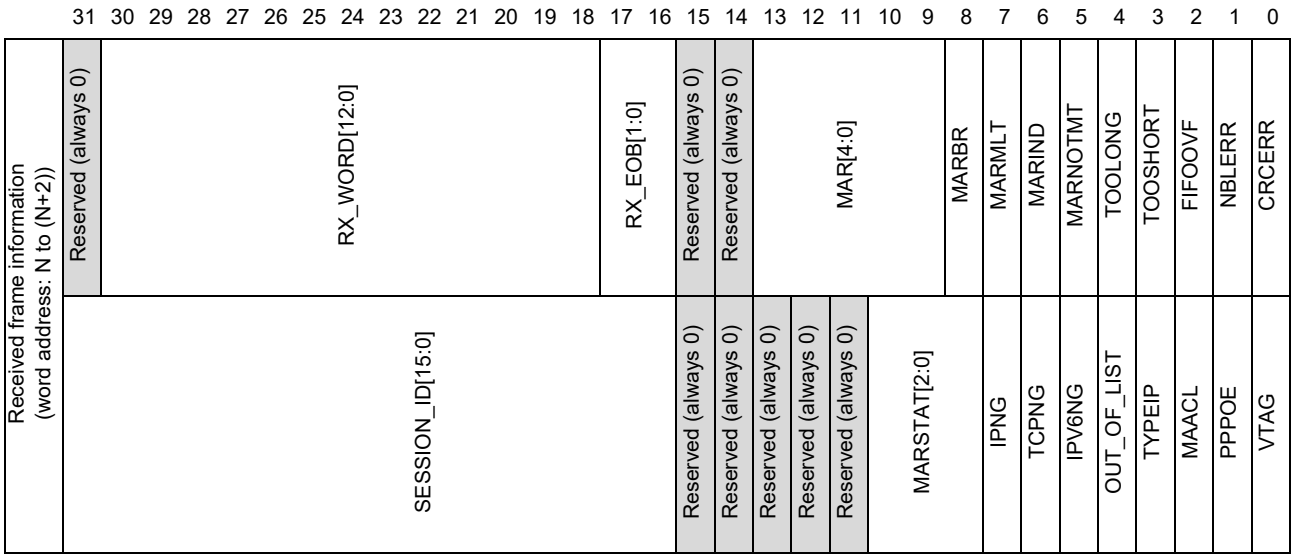

Figure 28.20 Received Frame Information

Item	Explanation
SESSION_ID[15:0]	If this field is set to ‘1’, it indicates Session ID of PPPoE Session Stage.
MARSTAT[2:0]	MARSTAT[2]: If this field is set to ‘1’, it indicates Broadcast Address. MARSTAT[1]: If this field is set to ‘1’, it indicates Multicast Address. MARSTAT[0]: If this field is set to ‘1’, it indicates Individual Address.
IPNG*2	If this field is set to ‘1’, it indicates that the checksum of the IPv4 header conflicts with the calculation result of the TCPIP accelerator.
TCPNG*2	If this field is set to ‘1’, it indicates that the checksum of the TCP or UDP header conflicts with the calculation result of the TCPIP accelerator.
IPV6NG*2	If this field is set to ‘1’, it indicates that the IPv6 extended header is one from among routing, Hop-by-Hop, or Destination Opt, and that the value of the header length field is incorrect.
OUT_OF_LIST*2	If this field is set to ‘1’, it indicates that a protocol number not listed below was detected in the IPv6 extended header. 06h: TCP header 11h: UDP header 00h: Hop-by-Hop 3Ch: Destination Opt 2Ch: Fragment 2Bh: Routing 3Bh: No next header 32h: ESP header 33h: AH header
TYPEIP*2	If this field is set to ‘1’, it indicates that an IP packet was received.
MAACL*2	If this field is set to ‘1’, it indicates that an 802.3 (LLC/SNAP) packet was received.
PPPOE*2	If this field is set to ‘1’, it indicates that a PPPoE packet was received.
VTAG*2	If this field is set to ‘1’, it indicates that the packet included a VLAN tag.
RX_WORD[12:0]	Number of Ethernet Frame words*1
RX_EOB[1:0]	Indicates the number of valid bytes in the last word of this frame.*1 00: 1 byte is valid. 01: 2 bytes are valid. 10: 3 bytes are valid. 11: 4 bytes are valid.
MAR[4:0]	MAR[4:1]: Unused (always 0) MAR[0]: Indicates that the Pause Packet destination address was received.

Item	Explanation
MARBR	If this field is set to ‘1’, it indicates that the receive frame is a Broadcast address.
MARMLT	If this field is set to ‘1’, it indicates that the receive frame is a Multicast address.
MARIND	If this field is set to ‘1’, it indicates that the receive frame is a packet from an address registered in the MAC address register.
MARNOTMT	If the receive frame is not an address for this station, this field is set to ‘1’.
TOOLONG	If this field is set to ‘1’, it indicates that the receive frame is longer than the maximum frame length (1518 octets).
TOOSHORT	If this field is set to ‘1’, it indicates that the receive frame is shorter than the minimum frame length (64 octets). This MAC never receives a packet in which TOOSHORT is ‘1’ because the TOOSHORT packet is automatically discarded.
FIFOOVF	If this field is set to ‘1’, it indicates that the FIFO buffer has overflowed during reception. When this occurs, the data of a received frame may be missing.
NBLERR	If this field is set to ‘1’, it indicates that the words in the receive frame have an error such as an encoding error.
CRCERR	If this field is set to ‘1’, it indicates that the receive frame has a CRC error.

Note 1. FCS (4 bytes) in the Ethernet frame and the padding (2 bytes) of the MAC header inserted by the reception TCPIP accelerator are also included in the number of received bytes.
Note 2. The values of these fields are ineffective if the TCPIP accelerator is disabled.

If RX_WORD[12:0] and RX_EOB[1:0] are combined into RX_LENGTH [14:0] (by using RX_WORD[12:0] as the upper bits and RX_EOB[1:0] as the lower bits), the number of bytes in the received frame can be calculated by using the following expression:

(Number of receive bytes in the Ethernet frame*1) = RX_LENGTH [14:0] - 3

Examples are as follows:

- When the size of receive data is 1 byte: RX_WORD = 1h, RX_EOB = 0h: 4 - 3 = 1 (byte)
- When the size of receive data is 8 bytes: RX_WORD = 2h, RX_EOB = 3h: 11 - 3 = 8 (bytes)
- When the size of receive data is 5 bytes: RX_WORD = 2h, RX_EOB = 0h: 8 - 3 = 5 (bytes)
- When the size of receive data is 9 bytes: RX_WORD = 3h, RX_EOB =0h: 12 - 3 = 9 (bytes)

Note 1. FCS (4 bytes) in the Ethernet frame and the padding (2 bytes) of the MAC header inserted by Ethernet MAC are also included in the number of receive bytes.

(2) Ethernet frame

The data format of received Ethernet frames is shown below.
For details on the Ethernet switch, see section 29, Ethernet Switch.

Item	Explanation
Destination MAC Address	MAC address of the transmission destination. If insertion of management tags is permitted by the Ethernet switch management TAG control register (ETHSWMTC), management TAG information is stored.
Source MAC Address	MAC address of the transmission source
Type/Length	Ethernet type or length
VLAN Tag	Tag protocol identifier: Used when a VLAN tag is included.
VLAN Info	Tag control information: Used when a VLAN tag is included.
Frame Payload	Payload
FCS	Frame check sequence: When the reception TCPIP accelerator is enabled and a received packet includes TCP/UDP, the FCS field is overwritten by the checksum value of TCP/UDP. This checksum value can be used for calculating the total checksum value of fragmented TCP/UDP packets.

(a) If insertion of management tags is permitted

If insertion of management tags is permitted by the Ethernet switch management TAG control register (ETHSWMTC), the Destination MAC Address [47:0] field is used as follows:

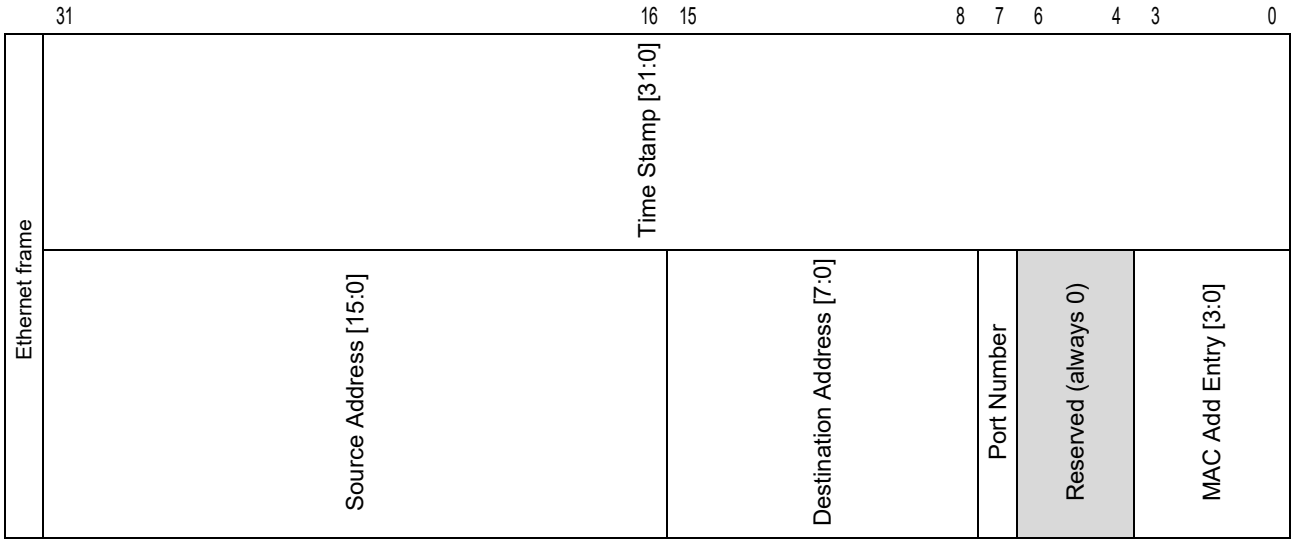

Figure 28.21 Destination MAC Address Field when Insertion of Management Tags is Permitted

Item	Explanation
Time Stamp [31:0]	Timestamp of the time at which the receive frame passed the port
MAC Add Entry [3:0]	Index number of the MAC address setting register (GMAC_ADRnA and GMAC_ADRnB) that matches the received frame Example: When the value is 5 The frame destination address corresponds to the setting of GMAC_ADR5A and GMAC_ADR5B.
Port Number	Port for which the receive timestamp was added
Destination MAC Address	MAC address of the transmission destination
Source MAC Address	MAC address of the transmission source

Note: When the AFILLTEREN bit in the GMAC_RXMODE register is 1, the value of the MAC Add Entry field is disabled and the destination MAC address is thus not stored.

(b) When the reception TCPIP accelerator is enabled and TCP/UDP packet data is not included

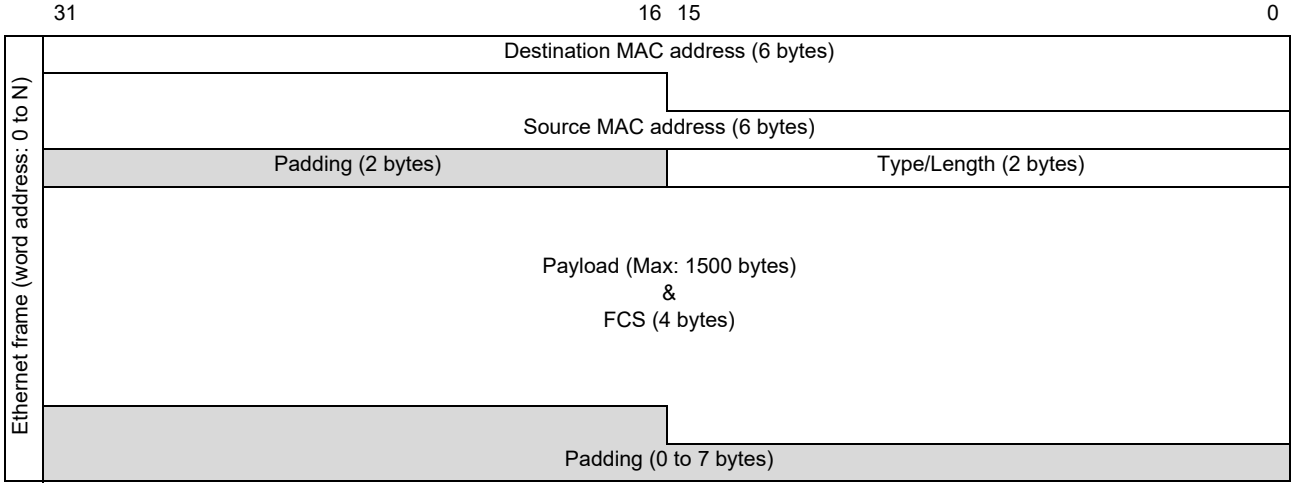

Figure 28.22 Received Ethernet Frame (TCPIPACC Enabled, VLAN Tag not Included, TCP/UDP not Included)

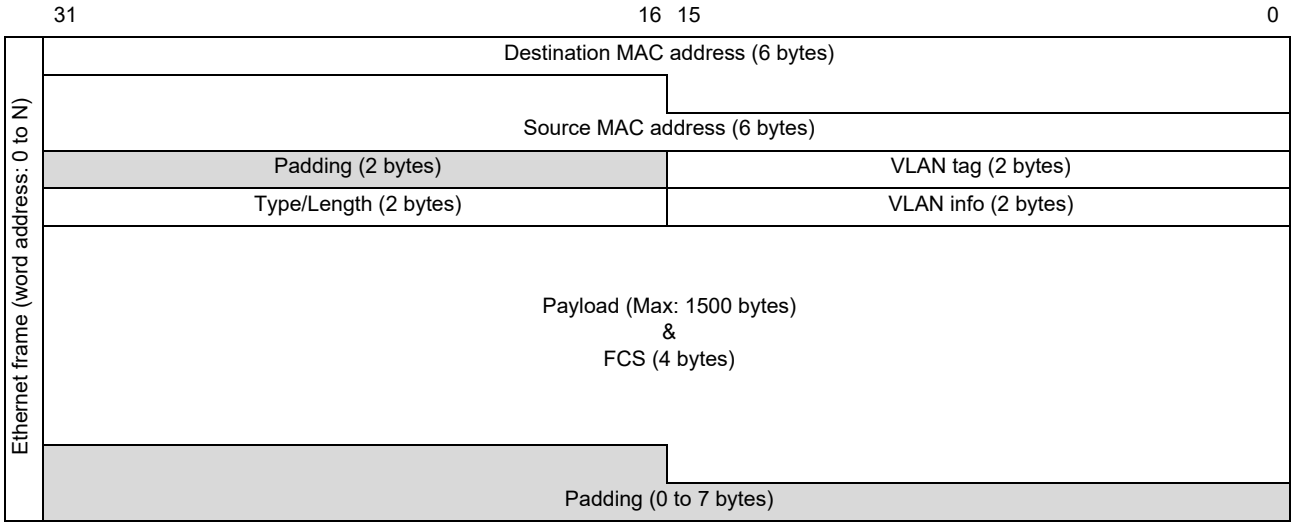

Figure 28.23 Received Ethernet Frame (TCPIPACC Enabled, VLAN Tag Included, TCP/UDP not Included)

(c) When the reception TCPIP accelerator is enabled and TCP/UDP packet data is included

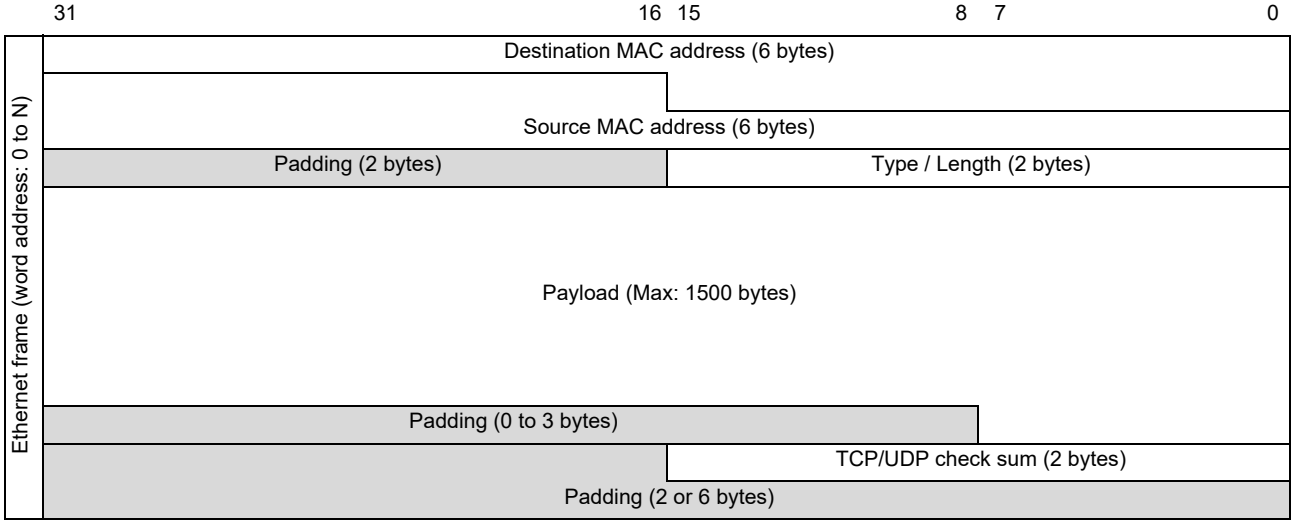

Figure 28.24 Received Ethernet Frame (TCPIPACC Enabled, VLAN Tag not Included, TCP/UDP Included)

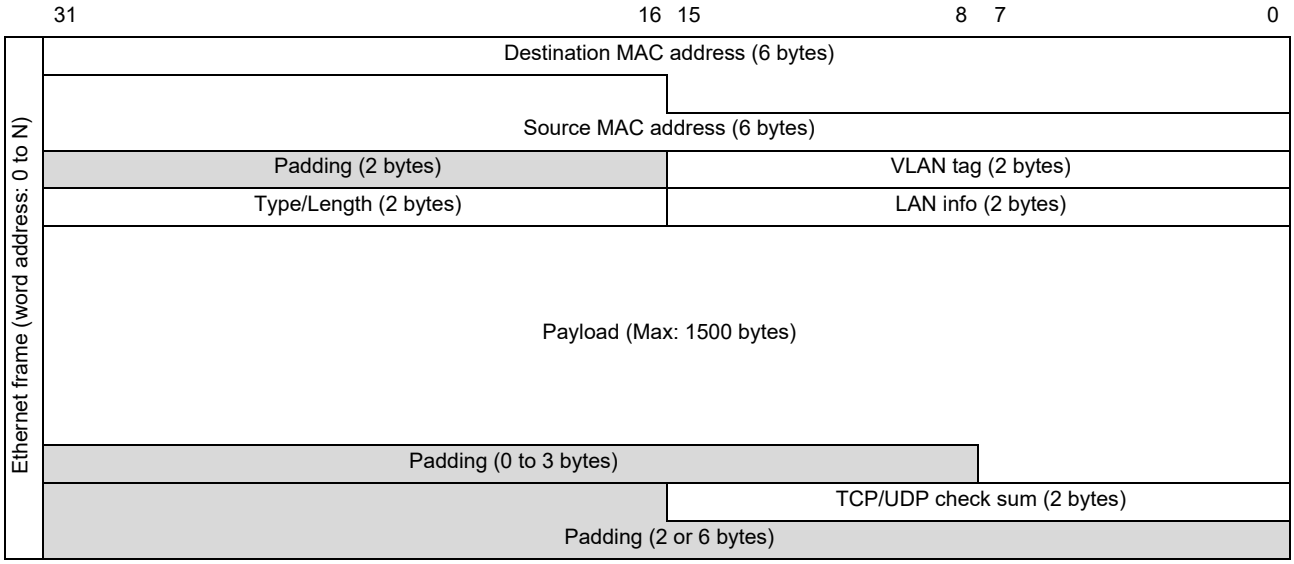

Figure 28.25 Received Ethernet Frame (TCPIPACC Enabled, VLAN Tag Included, TCP/UDP Included)

(d) When the reception TCPIP accelerator is disabled

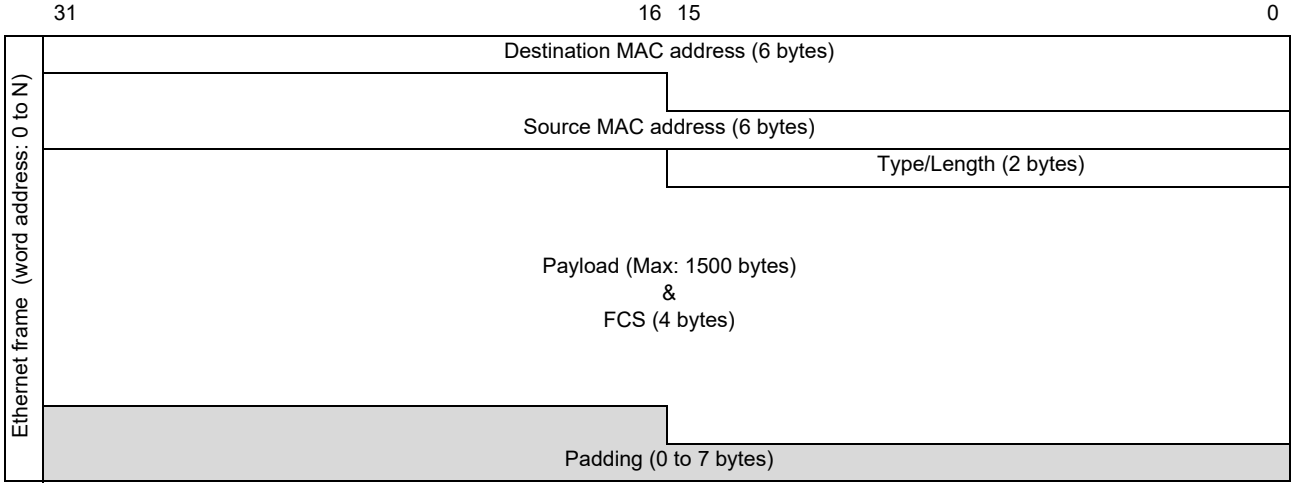

Figure 28.26 Received Ethernet Frame (TCPIPACC Disabled, VLAN Tag not Included)

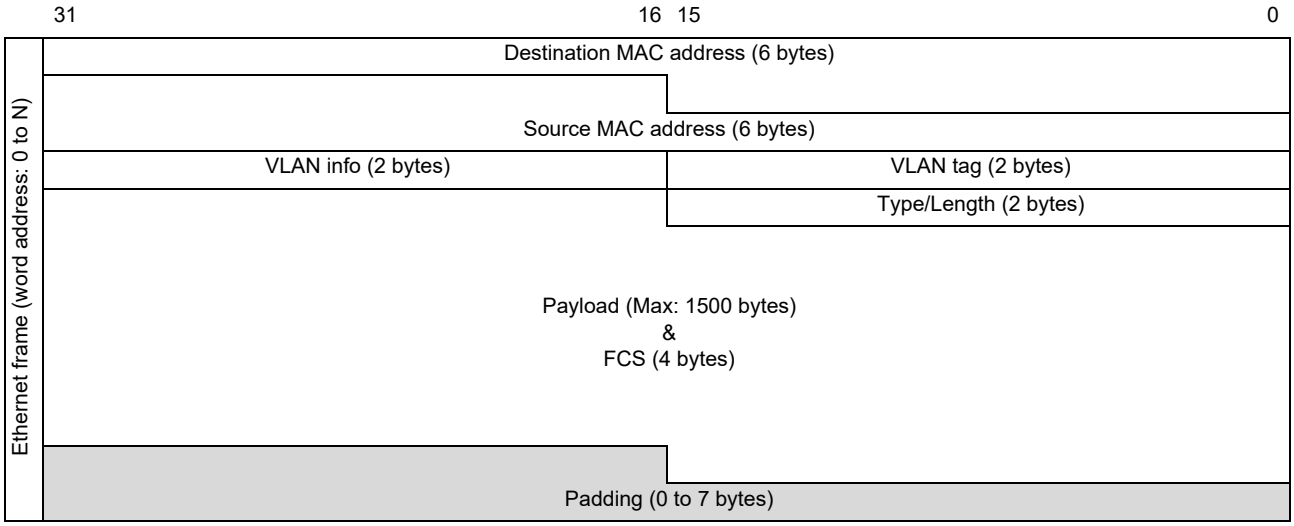

Figure 28.27 Received Ethernet Frame (TCPIPACC Disabled, VLAN Tag Included)

28.3.5 TCPIP Accelerator

With the TCPIP accelerator enabled, checksum calculations during transmission and reception can be executed by hardware. Frames for the following three protocols are checked by calculating the checksum.

- IPv4 header checksum
- TCP checksum
- UDP checksum

Usage of the TCPIP accelerator for transmission and reception is described below and on the next page.

28.3.5.1 Transmission with Use of the TCPIP Accelerator

Setting the TTCPIPEN bit in the GMAC_ACC register to 1 enables the TCPIP accelerator for transmission. When a packet for any from among IPv4, TCP/IP, or UDP/IP is transmitted in this state, hardware calculates the checksum and the checksum field for the given protocol is automatically overwritten and then transmitted. At this time, two bytes of padding for the TCPIP accelerator are required in the MAC header.
In addition, setting 1 in the TCPIP ACC OFF field of the transmission frame control information disables the transmission TCPIP accelerator for the packets.
For fragmented packets, hardware does not calculate the TCP and UDP checksums, so software should calculate the checksums.
When the TTCPIPEN bit in the GMAC_ACC register is 0, the transmission TCPIP accelerator is disabled.

Table 28.23 GMAC_ACC Register Settings and Transmission TCPIP Accelerator Operation

GMAC_ACC.TTCPIPEN	TCPIP ACC OFF Transmission Frame Control Information TCPIP ACC OFF	Calculation of Checksum (in Transmission)	Padding for TCPIPACC (in Transmission)
0	0	Disabled	Not required
0	1	Disabled	Not required
1	0	Enabled	Required
1	1	Disabled	Required

Note 1. If the result of calculating the UDP checksum of a packet for transmission is 0000h, write FFFFh to the checksum field.
Note 2. If the value of the header length field in an IPv4 header does not match the actual length of the header, transmission may not be completed and recovering normal operation may not be possible. Be sure to set the correct value.

28.3.5.2 Reception with Use of the TCPIP Accelerator

Setting the RTCPIPEN bit in the GMAC_ACC register enables the TCPIP accelerator for reception. When a packet for any from among IPv4, TCP/IP, or UDP/IP is received in this state, hardware calculates the checksum. If the result of calculation does not match the value of the packet's checksum field, error information is stored in the IPNG and TCPNG fields of the information on the received frame.

When TCPIPACC is enabled, two bytes of padding for the TCPIP accelerator are inserted in the MAC headers of received frames.

When the reception TCPIP accelerator is enabled and a received packet includes TCP/UDP, the FCS field is overwritten by the checksum value of TCP/UDP. This checksum value can be used for calculating the total checksum value of fragmented TCP/UDP packets. In the case of fragmented data, however, the pseudo-header does not include the checksum value, so software must be used to calculate the checksum value for the pseudo-header.

When any field from among IPNG, IPV6NG, or OUT_OF_LIST of the information on a received frame is 1, hardware does not calculate the TCP or UDP checksum for that frame.

Moreover, when the IPv6 extended header indicates any from among the fragment, ESP, and AH protocols, the TCP or UDP checksum is not calculated.

When the RTCPIPACC bit in the GMAC_ACC register is 1, the checksum is not calculated, but padding is inserted for the TCPIP accelerator.

When the RTCPIPEN bit in the GMAC_ACC register is 0, the reception TCPIP accelerator is disabled. In this case, padding for the accelerator is not assigned.

Table 28.24 GMAC_ACC Register Settings and Reception TCPIP Accelerator Operation

GMAC_ACC.RTCPIPEN	GAMC_ACC.RTCPIPACC	Calculation of Checksum (in Reception)	Padding for TCPIPACC (in Reception)	Overwriting of FCS Field with Calculated Checksum Value
0	0	Disabled	No	Not done
0	1	Disabled	No	Not done
1	0	Enabled	Yes	Done
1	1	Disabled	Yes	Not done

Note: If the checksum field of the UDP header of the received packet is 0000h, checksum comparison does not proceed. TCPNG becomes 0.

28.3.6 Protect Command Register

If a program runs out of control, the application might stop unexpectedly. To prevent such a problem, protect command registers are used to protect registers from write operations that might significantly affect the system. ETHERC has the following protect command registers:

- System protect command register (SPCMD)
- Ethernet system protect command register (ETSPCMD)

A write operation for a protected register can be performed only when the register is unlocked by setting the protection unlock enable bit of the SPCMD or ETSPCMD protect command register to ON (1).

To set a protect command register (to 1), only write operations performed in the following specific sequence are accepted. There is no special sequence for clearing the register (to 0) or reading it.

(1) Write 0000 00A5h to the protect command register as a specific value.
(2) Write 0000 00001h to the protect command register as an expected value.
(3) Write 0000 FFFEh to the protect command register as a reversal value.
(4) Write 0000 0001h to the protect command register as an expected value.

Note 1. In steps (2) and (3), no write operation is performed for the target register.
Note 2. After a write operation for the target register is completed, make sure that you clear the protect unlock enable bit (to 0) to enable protection.

The state transition is shown in the following diagram:

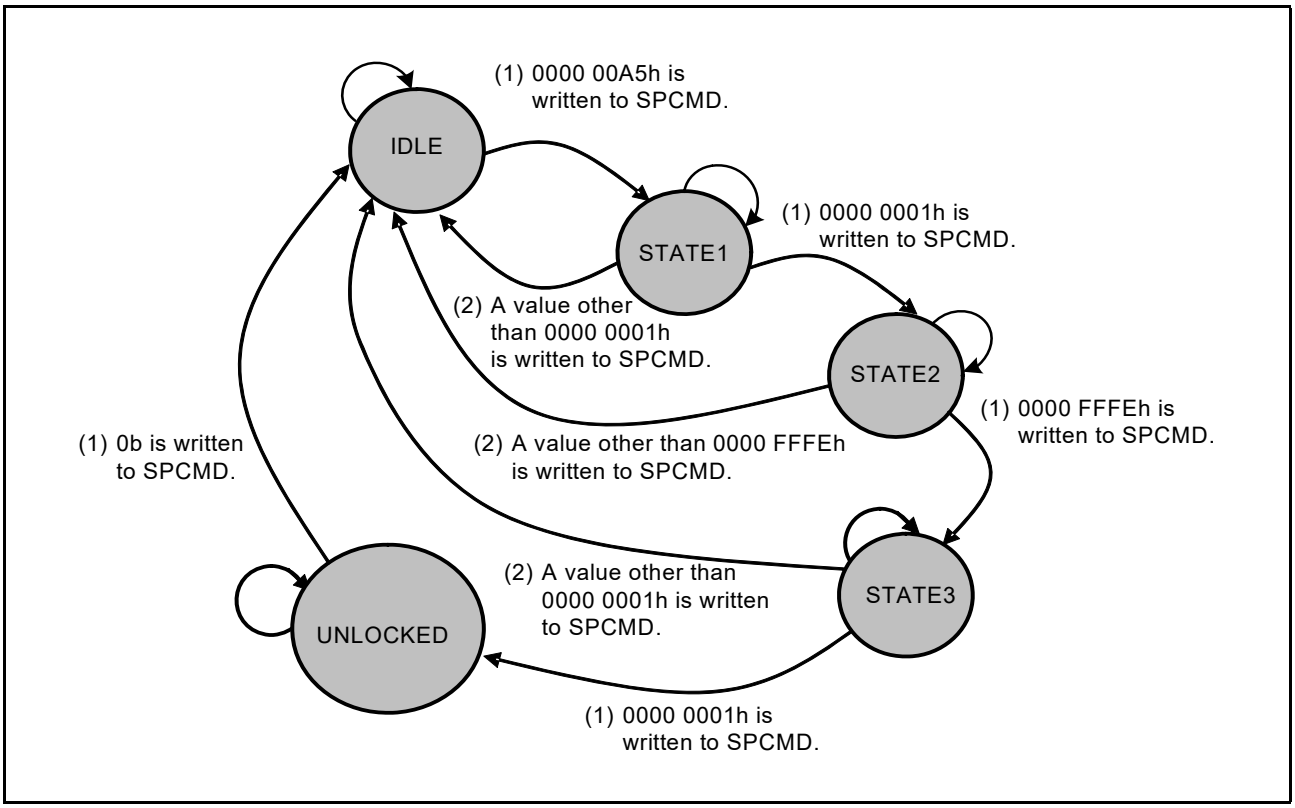

Figure 28.28 State Transition Diagram for a Protect Command Register (Example for the SPCMD Register)

28.4 Notes

The following sections describe points that must be noted.

28.4.1 Padding added to the MAC header in the transmit frame

In the gigabit Ethernet MAC, to enable the handling of data by the TCPIP accelerator, two bytes of padding are added to the 14-byte MAC headers to configure frames for transmission.
However, this padding is not actually sent. Therefore, note that it is not included in the data sizes of frames for transmission.
For details, see section 28.3.5.1, Transmission with Use of the TCPIP Accelerator.

28.4.2 Misjudgment of the Result of Checksum Calculation by Hardware in Reception

If the value of the checksum field in an IPv4 or TCP header included in the received packet is 0000h or FFFFh, the IPNG and TCPNG fields of the information on the received frame may be 1 even if the packet is actually normal (e.g., when the result of calculation by hardware is 0000h but the value of the checksum field in the header is FFFFh). Therefore, when both of the following conditions are satisfied, use software to check the checksum.

- IPNG or TCPNG is 1
- The value of the checksum field in the header is 0000h or FFFFh

28.4.3 Setting of the Module Stop Function

In the initial state, Ethernet-related functions are not activated. To use these functions, set the MSTPCRB.MSTPCRB16 to MSTPCRB.MSTPCRB19 bits to disable the module stop function. Note that after the module stop function is disabled, it must not be re-enabled. When the re-enabled module stop function is disabled again, correct operation cannot be guaranteed. It is possible to re-disable the module stop function after it is placed in the initial state (inactive state) by reset.

28.4.4 Misjudgment of the Result of Checksum Calculation in Reception

(1) Applicable to Ethernet II and IEEE802.3 + IEEE802.2 (LLC+SNAP) frames

If a frame which satisfies any of the following conditions has been received, the IPNG or TCPNG field of the information in the received frame may be 1 even if the packet is actually normal. Therefore, when this condition is satisfied, use software to check the checksum.

- The value of the checksum field in an IPv4 or TCP header is 0000h or FFFFh.
- The frame is not an IPv6 or FCS frame, its length is 60 or more bytes, the TCP or UDP payload is one byte, and the subsequent value is non-0.
- The calculated checksum value for a pseudo-header to be used in checksum calculation for IPv6, TCP, or UDP takes up 21 or more bits.

(2) Applicable to IEEE802.3 + IEEE802.2 (LLC) frames

If an IEEE802.3 + IEEE802.2 (LLC) frame with no SNAP extension is received, the value of the TYPEIP and IPNG fields may become 1. If this condition is met, use software to check whether the frame has a SNAP extension and handle it as a normal frame if it has no SNAP extension.

28.4.5 Incorrect Information on Received Frames when the Reception FIFO Overflows

If the reception FIFO buffer overflows while the reception TCPIP accelerator is enabled, information that is incorrect in the ways described below may be stored as information on the received frame.

- Error information on a previously received frame that caused the reception FIFO buffer to overflow is stored as information on a frame received as a normal frame.
- The received frame that caused the reception FIFO buffer to overflow is recognized as a normal frame and an incorrect value is stored as information on the received frame.

As a workaround for this, take action (1) or (2) below.

(1) Disable the inclusion of padding insertion in MAC headers by the reception TCP/IP accelerator. Specifically, clear bit 0 in the GMAC_ACC register.

(2) If the reception FIFO buffer overflows, discard all remaining frames in the reception FIFO buffer and in buffer RAM.
Specifically, take the following measures when the reception FIFO buffer overflows.
1. Stop the reception MAC.
2. Discard all remaining frames in the reception FIFO.
3. Discard all remaining frames in the buffer RAM.
4. Restart the reception MAC.
5. Discard frames in which the setting of the VALID bit of BUFID is 1 at least once. This measure is taken to discard residual frames by receiving a normal frame once, because, in the case of frames that cause overflows, FIFO Empty may be read from the register even while frames remain in the FIFO buffer.

Figure 28.29 to Figure 28.32 are example flowcharts to handle processing to accomplish the items in point (2).

- The following apply when the HW-RTOS is in use in a product with an R-IN Engine
  Figure 28.29: Example Task for Processing to Handle Overflows of the Reception FIFO Buffer
  Figure 28.30: Example Task to Handle Reception Processing

√ Prepare the overflow processing task so that it has higher priority than the reception processing task.
√ Make the setting to start task processing by the HWISR for overflow error interrupts.
√ Wait for the completion of the HWISR for reception interrupts before discarding the last frame.

- The following apply when the HW-RTOS may be unused with products that have no R-IN Engine or with products that have an R-IN Engine.
  Figure 28.31: Example of Processing for Reception FIFO Overflow Interrupts
  Figure 28.32: Example of Processing for Reception

√ Discard the last frame in reception processing. Discard valid data once if the return-from-overflow processing flag has been set.
√ Disable overflow interrupts during the period from reading of BUFID to checking of the return-from-overflow processing flag.

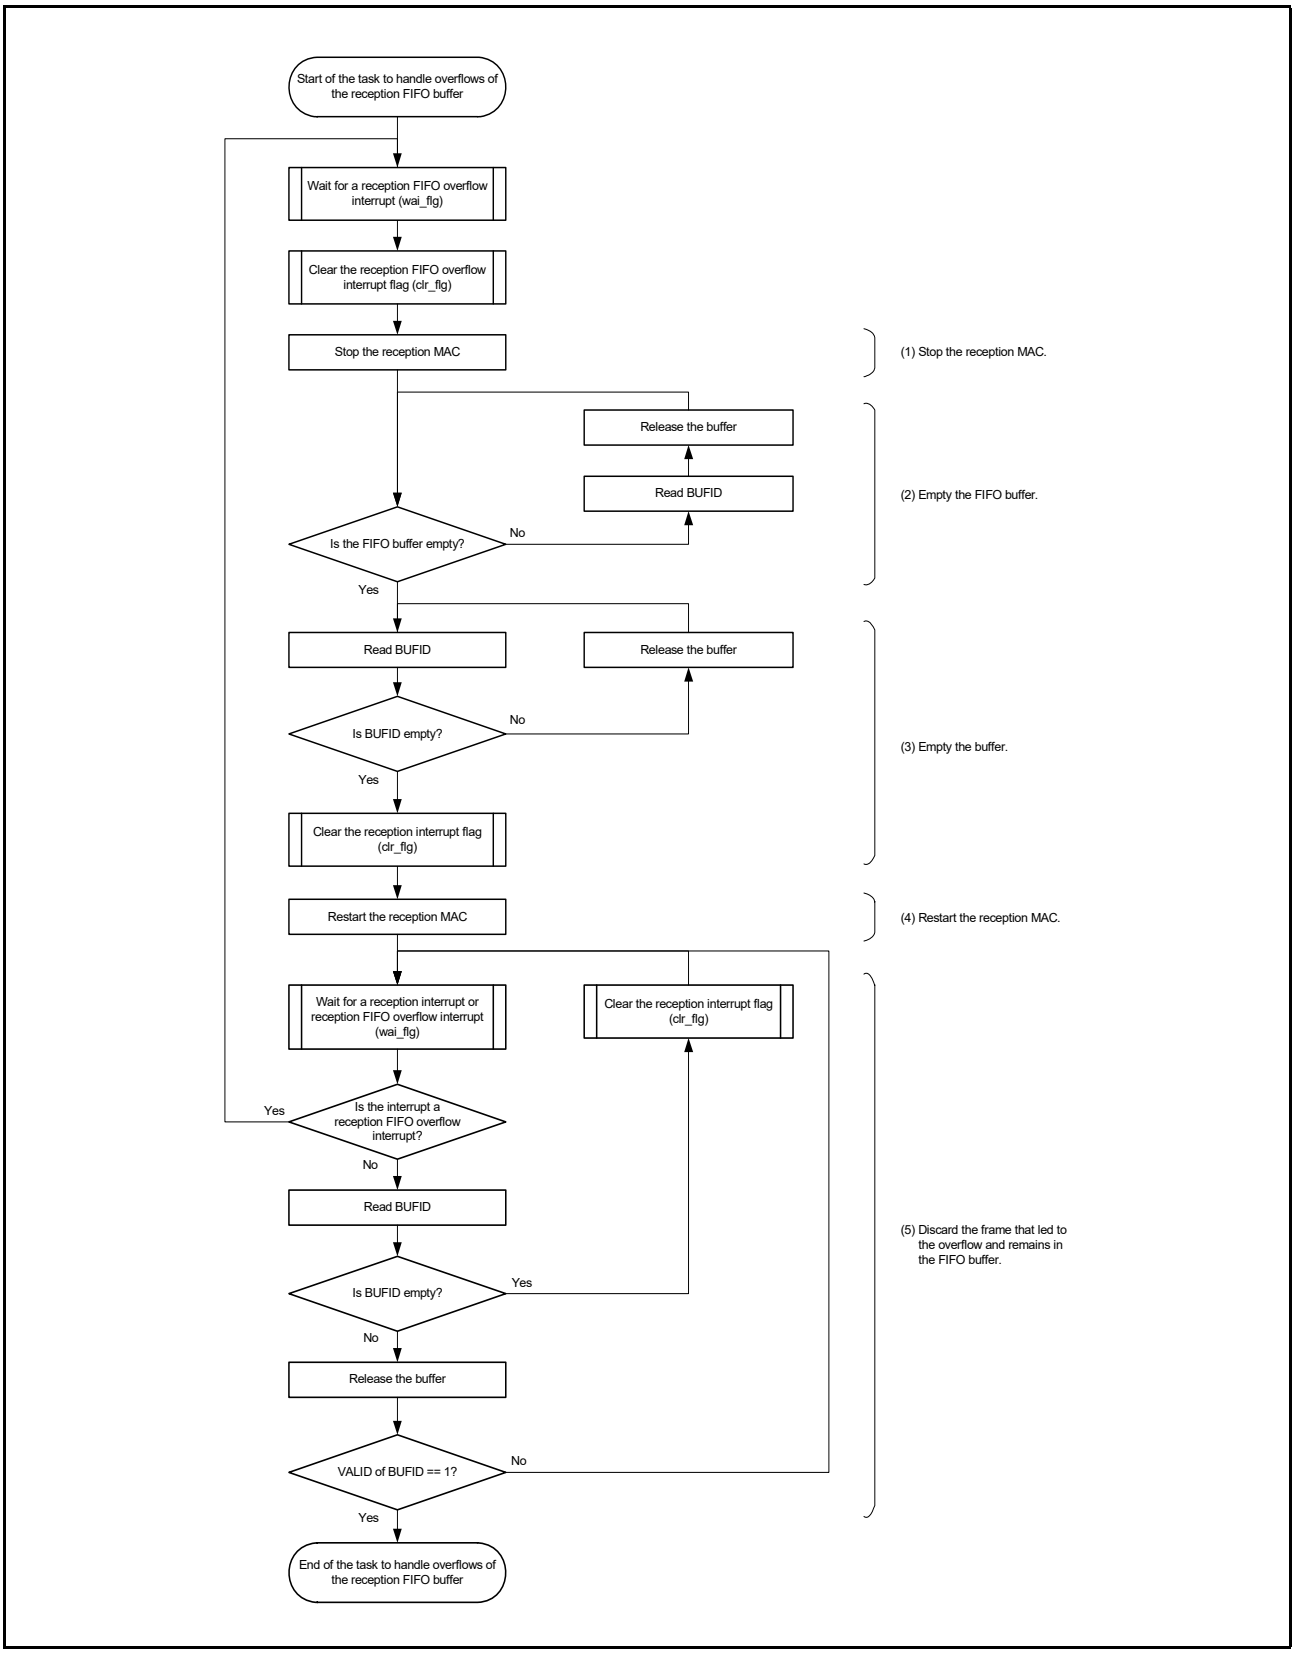

Figure 28.29 Example Task to Handle Overflows of the Reception FIFO Buffer (when the HW-RTOS is in Use)

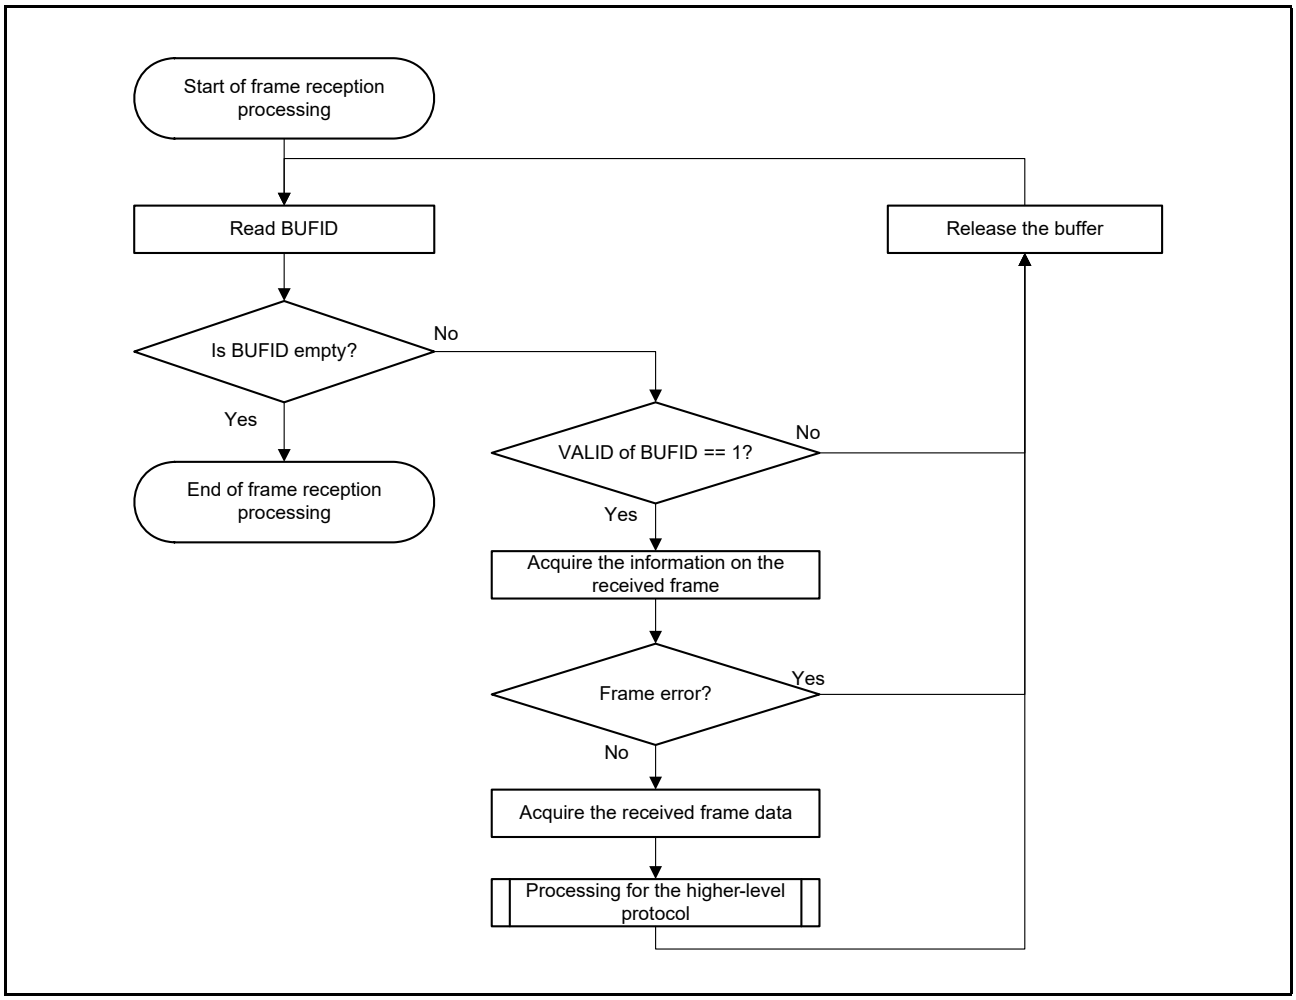

Figure 28.30 Example Task to Handle Reception Processing (when the HW-RTOS is in Use)

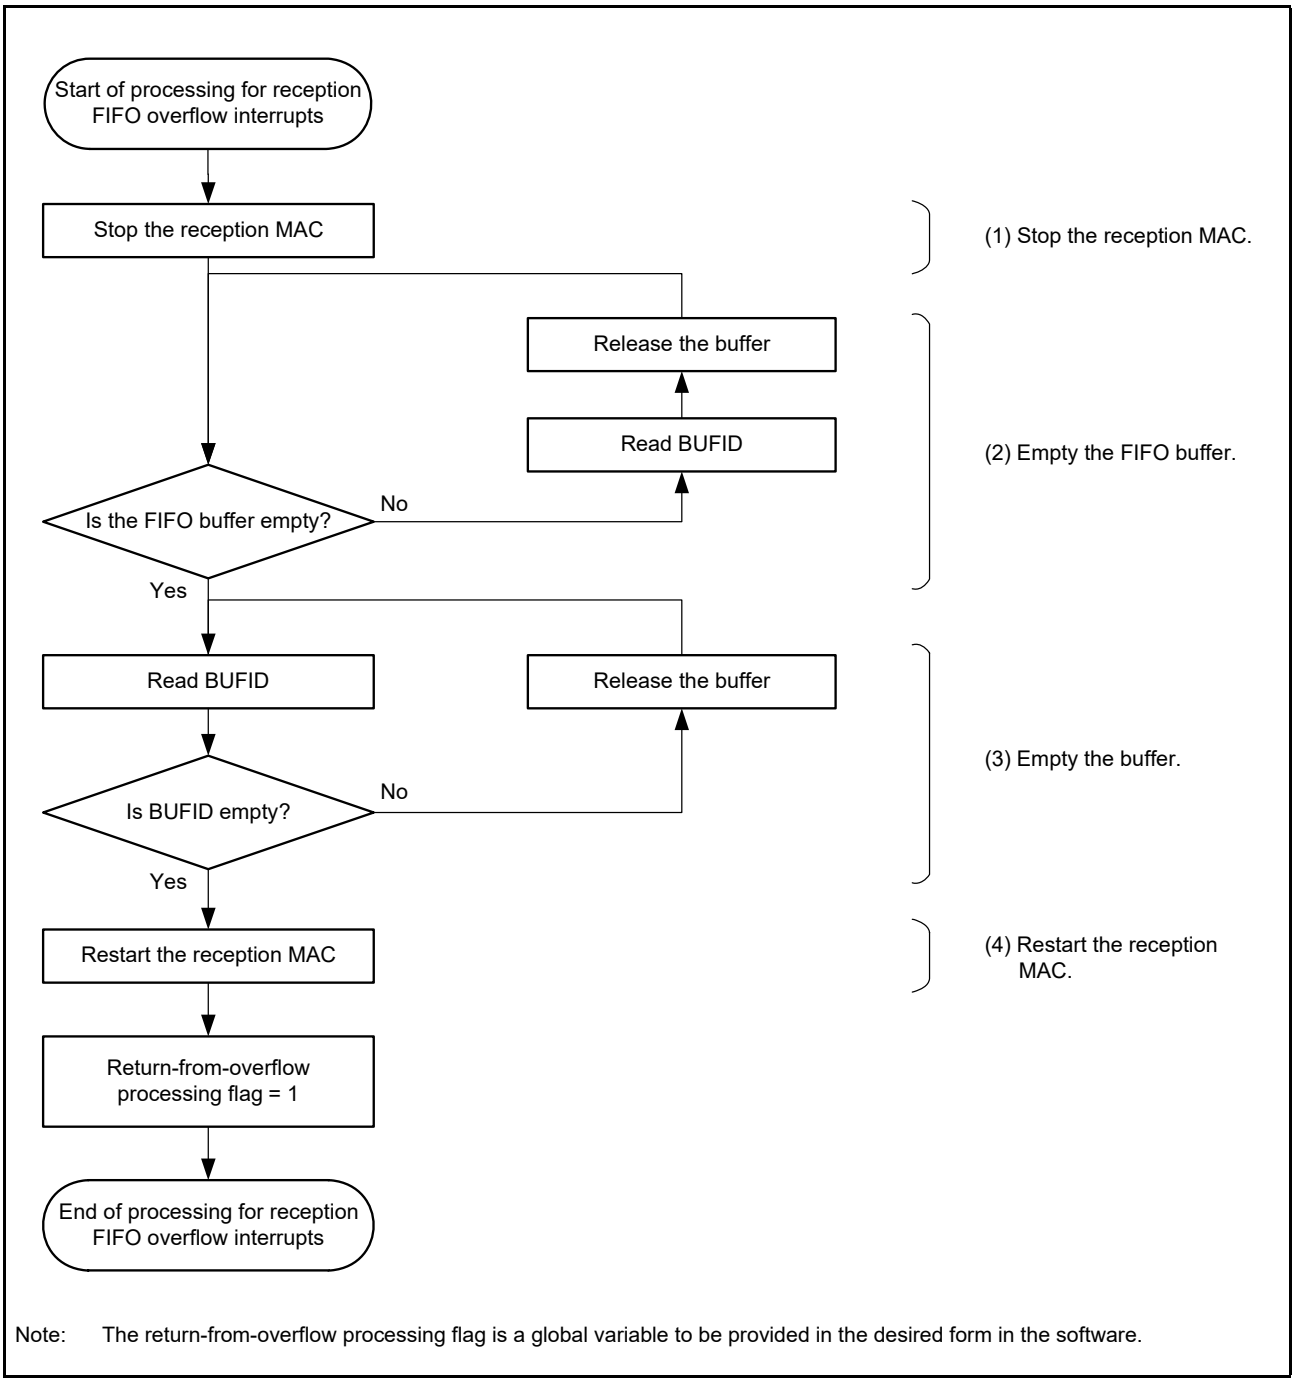
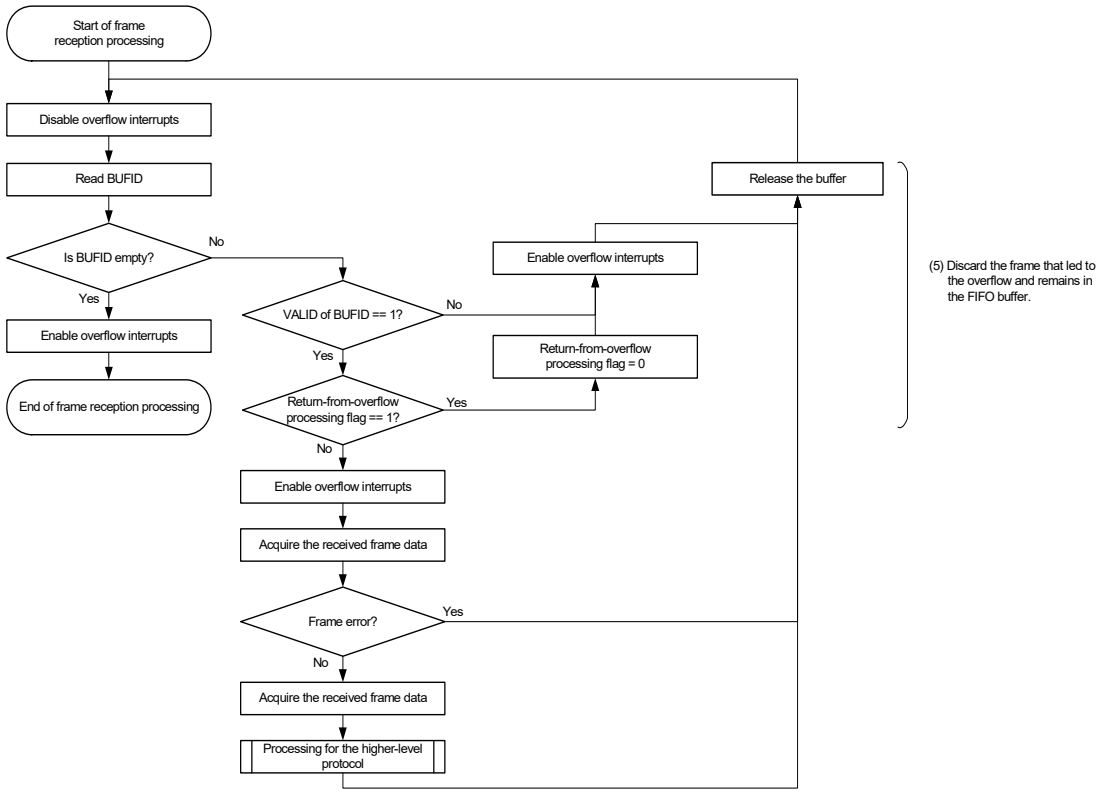


Note: The return-from-overflow processing flag is a global variable to be provided in the desired form in the software.

Figure 28.31 Example of Processing for Reception FIFO Overflow Interrupts (when the HW-RTOS is Not in Use)



Note: The return-from-overflow processing flag is a global variable to be provided in the desired form in the software.

Figure 28.32 Example of Processing for Reception (when the HW-RTOS is Not in Use)

28.4.6 Incorrect Information on Received Frames with Size, Inclusive of Padding, Exceeding 64 Bytes

If a frame which satisfies all conditions listed below is received while the reception TCPIP accelerator is enabled, the number of received words (RX_WORD[12:0]) indicated as information on the received frame may be greater or lower by one word (one word here meaning 4 bytes) than the actual number. In cases where it is lower by one word, the information may indicate an amount of data corresponding to the loss of the IP packet. However, this does not necessarily mean that the received IP packet was actually lost.

- The size of the frame including the frame check sequence (FSC) exceeds 64 bytes.
- The frame contains a TCP/IP or UDP/IP packet.
- The frame includes padding (a trailer) between the IP packet and the FCS.

As a workaround for this, take action (1) or (2) below.

(1) Disable the reception TCP/IP accelerator or turn its support for checksum calculation off.
Specifically, clear bit 0 or set bit 2 in the GMAC_ACC register.

(2) To prevent the loss of data, add one word to the number of received words in the case of IP packets and pass the packets to the higher-levels of the stack for processing. In the higher-levels, acquire the payload in the form of the IP packet based on the total length of the IP header and discard subsequent data. Figure 28.33 is an example flowchart of processing for reception.

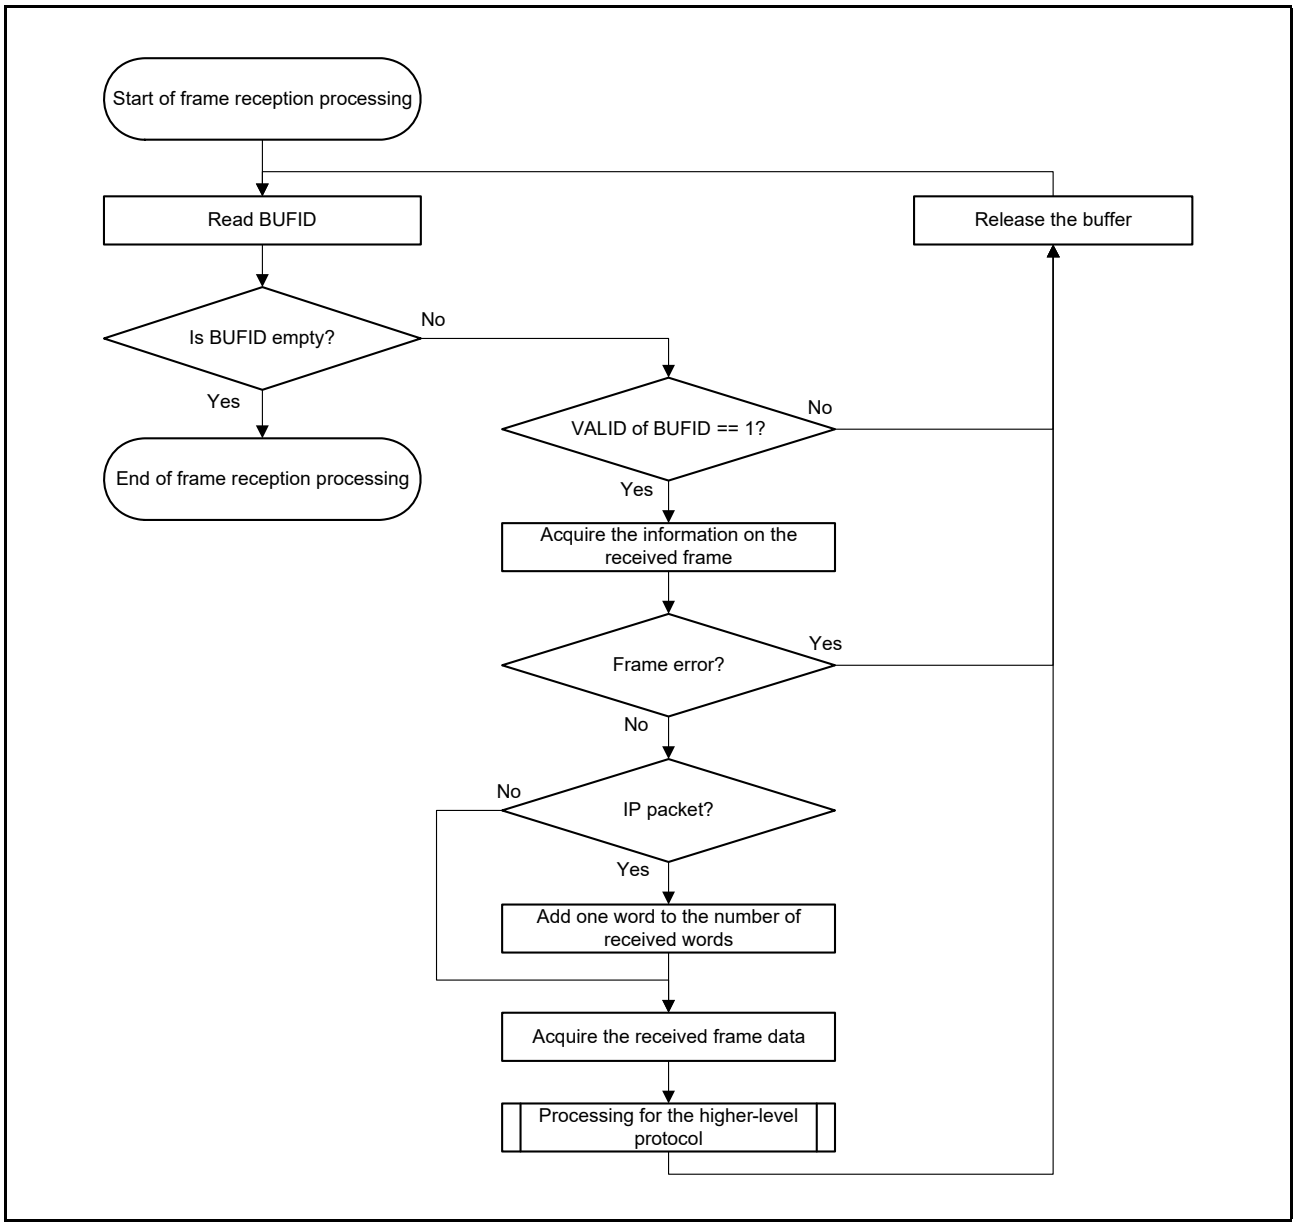


Figure 28.33 Example of Processing for Reception

28.4.7 Frame with Size Exceeding 1518 Bytes

This product does not support transfer of frames (jumbo frames) whose size exceeds 1518 bytes.

28.4.8 Use of Hardware Real-Time OS

For products incorporating an R-IN engine, when a hardware function call is executed while dispatching by the hardware real-time OS (HW-RTOS) is disabled, the call will not be executed successfully. To avoid this, be sure to execute hardware function calls while dispatching by the HW-RTOS is enabled. When the Cortex-R4 has control of the Ethernet MAC, however, it is not synchronized with the HW-RTOS, so the correct enabling and disabling of dispatching is not possible. Therefore, do not use the HW-RTOS while the Cortex-R4 is controlling the Ethernet MAC.

29. Ethernet Switch

This LSI has the Ethernet switch function.

29.1 Overview

With the Ethernet switch function, the LSI enables to build the network topology such as line and ring type without external switching hub.
Use of the Ethernet switch and mode setting are controlled by the related registers.
The specifications of the Ethernet switch are summarized in Table 29.1.

Table 29.1 Ethernet Switch Specifications

Item	Description
Function	• 2-port PHY interfaces • IEEE802.3 • 10BASE, 100BASE • Full and half duplex • Hardware switching, lookup, and filtering • QoS with frame prioritization • Priority control based on VLAN Priority (IEEE802.1Q), which enables priority reassignment • Classification and priority assignment based on IPv4 DiffServ Code Point Field, IPv6 Class of Service • Queue with four priority levels • Multicasting and broadcasting • VLAN frame • IEEE1588 timer module • Cut-through and hub features • Device level ring (DLR)

Figure 29.1 and Figure 29.2 are block diagrams of the Ethernet interface.
Gray modules and registers are described in section 28, Ethernet MAC (ETHERC), and section 30, EtherCAT Slave Controller (optional). See the related sections regarding the other registers and modules which are needed to operate the Ethernet switch.

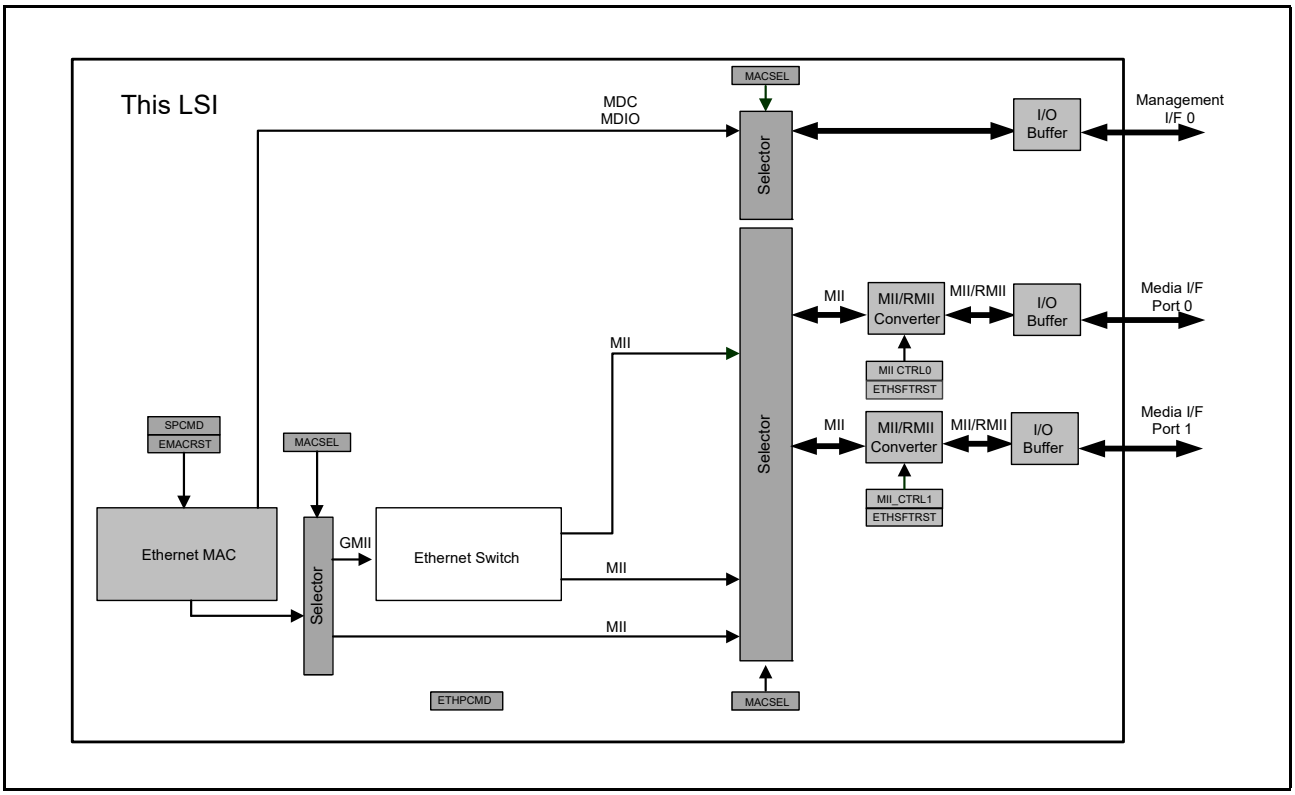

Figure 29.1 Block Diagram of the Ethernet Interface

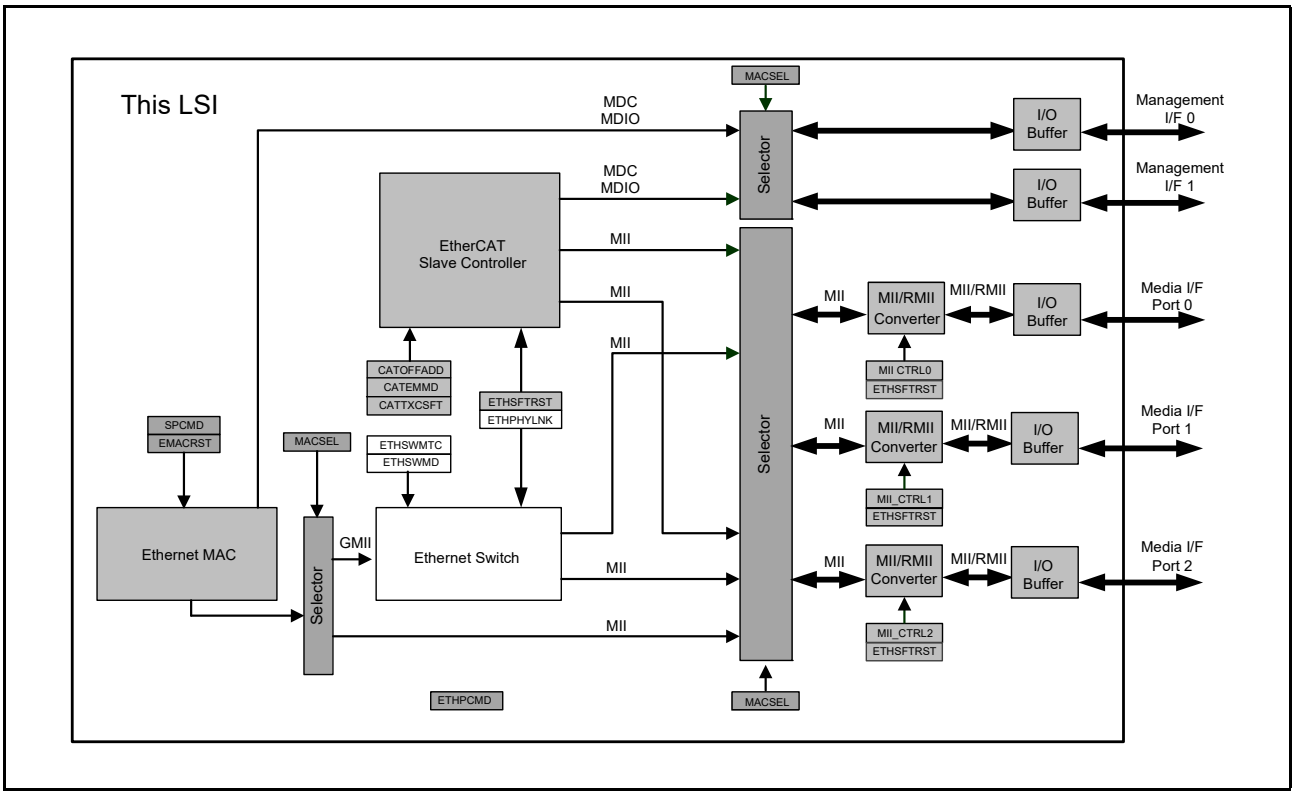

Figure 29.2 Block Diagram of the Ethernet Interface (for products incorporating an EtherCAT (optional))

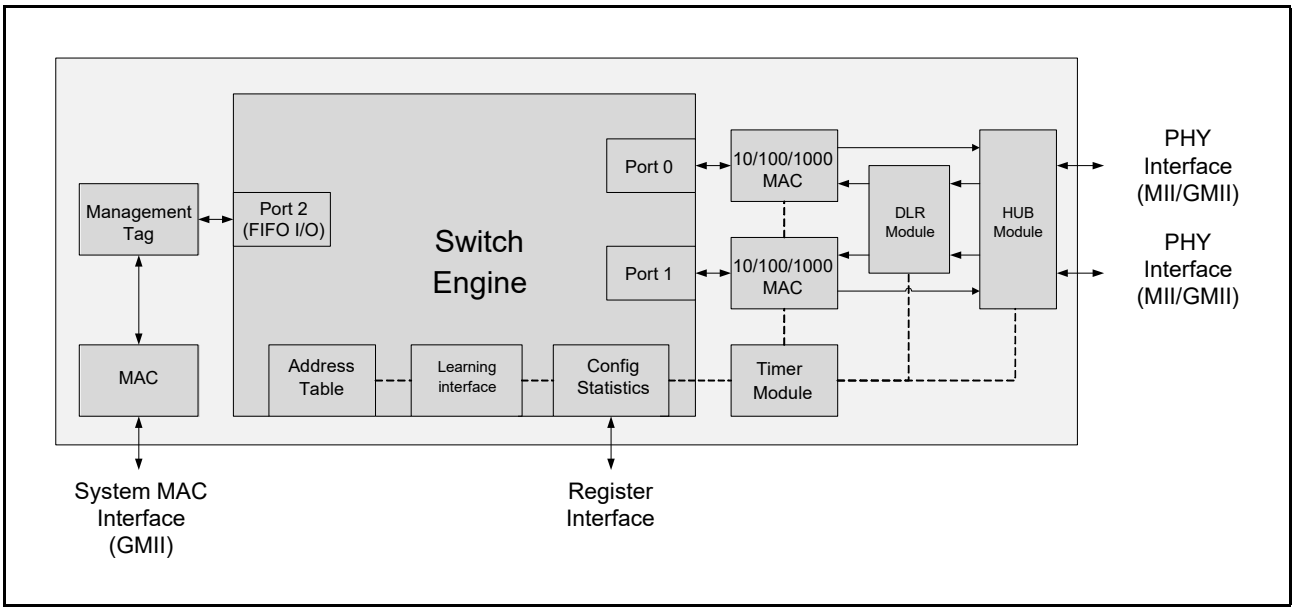

Figure 29.3 Ethernet Switch Overview

29.2 Register Description

29.2.1 Operating Mode Setting Registers

29.2.1.1 Ethernet PHY LINK Mode Register (ETHPHYLNK)

This register is used to specify the active level of the LINK signal of the Ethernet interface.

Note: This register is write-protected and can only be written after being protection-unlocked by using a special instruction sequence initiated through the Ethernet system protection command register (ETSPCMD) (For ETSPCMD, see section 28, Ethernet MAC (ETHERC)). For how to unlock protection, see section 28.2.1.3, Ethernet System Protect Command Register (ETSPCMD). No special instruction sequence is required for reading this register.

Address ETHERSW.ETHPHYLNK A00B F014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Note 1. These bits are only for products incorporating an EtherCAT (optional).

Bit	Symbol	Bit Name	Description	R/W
b0	SWLINK0	PHYLINK0 Pin Active Level Switching in Use with Ethernet Switch	Specify the active level of the PHYLINK0 signal using the Ethernet switch interface. 0: Active-High PHYLINK signal (value after reset). 1: Active-Low PHYLINK signal.	R/W
b1	SWLINK1	PHYLINK1 Pin Active Level Switching in Use with Ethernet Switch	Specify the active level of the PHYLINK1 signal using the Ethernet switch interface. 0: Active-High PHYLINK signal (value after reset). 1: Active-Low PHYLINK signal.	R/W
b2	CATLINK0*1	PHYLINK0 Pin Active Level Switching in Use with EtherCAT	Specify the active level of the PHYLINK0 signal using the EtherCAT interface. 0: Active-High PHYLINK signal. 1: Active-Low PHYLINK signal (value after reset).	R/W
b3	CATLINK1*1	LINK1 Pin Active Level Switching in Use with EtherCAT	Specify the active level of the PHYLINK1 signal using EtherCAT interface. 0: Active-High PHYLINK signal. 1: Active-Low PHYLINK signal (value after reset).	R/W
b31 to b4	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Note 1. These bits are only for products incorporating an EtherCAT (optional). For other products, these bits are reserved. They are read as 0. The write value should always be 0.

29.2.1.2 Ethernet Switch Management TAG Control Register (ETHSWMTC)

This register is used to specify management tag information when Ethernet switching is used.

Note: This register is write-protected and can only be written after being protection-unlocked by using a special instruction sequence initiated by using the Ethernet system protection command register (ETSPCMD) (For ETSPCMD, see section 28, Ethernet MAC (ETHERC)). For how to unlock protection, see section 28.2.1.3, Ethernet System Protect Command Register (ETSPCMD). No special instruction sequence is required for reading this register.

b1	P0HDMODE	Port 0 Transfer Mode Setting	Specifies the transfer mode of port 0. 0: Full-duplex mode 1: Half-duplex mode	R/W
b2	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b3	P1HDMODE	Port 1 Transfer Mode Setting	Specifies the transfer mode of port 1. 0: Full-duplex mode 1: Half-duplex mode	R/W
b31 to b4	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.1.4 Ethernet Switch 10-Mbps/Half-Duplex Mode Setting Register (ETHSW10HDEN)

This register is used to mask inputs on the ETHn_RXDV pins (Read Data Valid) by using the Ethernet switching function.
In transfer of 10-Mbps/half-duplex data, the data are looped back from TX (transmission data) to RX (reception data) by using some Ethernet PHYs. If these PHYs are used with the Ethernet switching function of this device for loop-back operation between two ports, the data are repeatedly transferred between the ports without involving Ethernet.
If the Ethernet PHY you are using is applied to the case described above, make sure to set the bits of this register to 1 (to enable masking).

Address(es): A00F 201Ch
For accesses from the Cortex-M3:
Address 400F 201Ch (products incorporating an R-IN Engine)

b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

29.2.2 Switch Configuration Registers

29.2.2.1 Port Enable Register (PORT_ENA)

This register is used to enable or disable each port of the Ethernet switch. A disabled port does not transmit frames, but can still receive frames.

Address(es): ETHERSW.PORT_ENA A00C 0008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	P0ENA	Port 0 Enable Setting	Enables or disables port 0 0: Disabled 1: Enabled	R/W
b1	P1ENA	Port 1Enable Setting	Enables or disables port 1 0: Disabled 1: Enabled	R/W
b2	P2ENA	Internal Interface Enable Setting	Enables or disables the internal interface port (port 2) 0: Disabled 1: Enabled	R/W
b31 to b3	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.2 Unicast Default Mask Register (UCAST_DEFAULT_MASK)

This register is used to mask unicast frames of each port of the Ethernet switch. When the destination address is unicast and not found in the address table, the frame is transferred to the ports where the mask is enabled.

Address(es): ETHERSW.UCAST_DEFAULT_MASK A00C 000Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	P2UCASTDM	P1UCASTDM	P0UCASTDM
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	P0UCASTDM	Port 0 Unicast Default Mask Setting	Selects the default unicast mask of port 0 0: Invalid 1: Valid When masking is enabled, frames are transferred to port 0 even if the addresses of the frames are not found in the address table.	R/W
b1	P1UCASTDM	Port 1 Unicast Default Mask Setting	Selects the default unicast mask of port 1 0: Invalid 1: Valid When masking is enabled, frames are transferred to port 1 even if the addresses of the frames are not found in the address table.	R/W
b2	P2UCASTDM	Internal Interface Unicast Default Mask Setting	Selects the default unicast mask of the internal interface (port 2). The internal interface does not generally need to receive unnecessary unicast traffic, so in most of cases, a mask setting is not required. Either of the following is required when a mask is not set: statically setting its own unicast address in the table of the switch or letting the interface learn dynamically based on the results of previous transfers. 0: Invalid 1: Valid When masking is enabled, frames are transferred to port 2 even if the addresses of the frames are not found in the address table.	R/W
b31 to b3	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.3 Broadcast Default Mask Register (BCAST_DEFAULT_MASK)

This register is used to mask broadcast frames of each port of the Ethernet switch. When the destination address is broadcast, the frame is transferred to the ports given in this mask.

Address(es): ETHERSW.BCAST_DEFAULT_MASK A00C 0014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	P0MCASTDM	Port 0 Default Multicast Mask Setting	Select the default multicast mask of port 0. 0: Invalid 1: Valid When masking is enabled, frames are transferred to port 0 if the destination addresses of the frames are multicast addresses.	R/W
b1	P1MCASTDM	Port 1 Default Multicast Mask Setting	Select the default multicast mask of port 1. 0: Invalid 1: Valid When masking is enabled, frames are transferred to port 1 if the destination addresses of the frames are multicast addresses.	R/W
b2	P2MCASTDM	Internal Interface Default Multicast Mask Setting	Select the default multicast mask of the internal interface port (port 2). 0: Invalid 1: Valid When masking is enabled, frames are transferred to port 2 if the destination addresses of the frames are multicast addresses.	R/W
b31 to b3	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.5 Input Learning Blocking Register (INPUT_LEARN_BLOCK)

This register is used to set address learning function and frame blocking function of each port of the Ethernet switch. When learning is disabled for a port (bit = 1), only bridge protocol data units (BPDU) are targeted for learning, all other frames are ignored. When blocking is enabled for a port (bit = 1), only bridge protocol data unit frames will be received, while other frames will be discarded on the port and not be transferred to other ports.

Address(es): ETHERSW.INPUT_LEARN_BLOCK A00C 001Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	P2LEARNDIS	P1LEARNDIS	P0LEARNDIS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	P2BLOCKEN	P1BLOCKEN	P0BLOCKEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	P0BLOCKEN	Port 0 Input Port Blocking Setting	Sets the blocking function of port 0 0: Invalid 1: Valid	R/W
b1	P1BLOCKEN	Port 1 Input Port Blocking Setting	Sets the blocking function of port 1 0: Invalid 1: Valid	R/W
b2	P2BLOCKEN	Internal Interface Input Port Blocking Setting	Sets the blocking function of the internal interface port (port 2) 0: Invalid 1: Valid	R/W
b15 to b3	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b16	P0LEARNDIS	Port 0 Address Learning Setting	Sets the address learning of port 0 0: Valid 1: Invalid	R/W
b17	P1LEARNDIS	Port 1 Address Learning Setting	Sets the address learning of port 1 0: Valid 1: Invalid	R/W
b18	P2LEARNDIS	Internal Interface Address Learning Setting	Sets the address learning of the internal interface port (port 2) 0: Valid 1: Invalid	R/W
b31 to b19	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.6 Management Configuration Register (MGMT_CONFIG)

This register is used to configure the bridge management port of the Ethernet switch and to enable the management port that receives bridge protocol frames. It is necessary to set the internal interface port (port 2) in the management port.

Address(es): ETHERSW.MGMT_CONFIG A00C 0020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	P1PORTMASK	P0PORTMASK
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PRIORITY			—	—	—	—	—	DISCARD	ENABLE	MSGTRANS	—	—	—	PORT	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PORT	Management Port Setting	Set the port that should act as a management port. These bits must always be set to 10b since it is necessary to set the internal interface port (port 2) in the management port.	R/W
b4 to b2	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b5	MSGTRANS	Message Transfer Status	This bit is set to 1 when a message is transmitted from the management port to any output port. Write 0 to this bit for a reset.	R/W
b6	ENABLE	Setting of Transfer to Management Port	Sets transfer of the BPDU frame to the management port. 0: Bridge protocol frames are forwarded as any other frame, or discarded if the DISCARD bit is set to 1. 1: All bridge protocol frames are forwarded exclusively	R/W
b7	DISCARD	BPDU Frame Discard Setting	Sets BPDU Frame Discard BPDU frames are always discarded when setting this bit to 1. Always set this bit to 0 if the ENABLE bit is set to 1. 0: Disabled 1: Enabled	R/W
b12 to b8	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b15 to b13	PRIORITY	Management Frame Priority Setting	Set priority of the management frames to be transmitted. Used to transmit a management frame faster than a normal frame. The priority in the output queue can be set to a higher priority level.	R/W
b16	P0PORTMASK*1	Port 0 Management Frame Transfer Mask Setting	Sets mask for transferring management frames from the management port to port 0. Setting this bit to 1 forcibly transfers only BPDU frames to port 0. Any other frames have no effect. 0: Invalid 1: Valid	R/W
b17	P1PORTMASK*1	Port 1 Management Frame Transfer Mask Setting	Sets mask for transferring of management frames from the management port to port 1. Setting this bit to 1 forcibly transfers only BPDU frames to port 0. Any other frames have no effect. 0: Invalid 1: Valid	R/W
b31 to b18	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Note 1. The herein specified PORTMASK takes precedence over the forced forwarding per each frame by management tag when a BPDU frame is forwarded. Hence it should be set to 0 when tag controlled forced forwarding is used.

29.2.2.7 Mode Configuration Register (MODE_CONFIG)

This register is used to reset the statistics counter in the Ethernet switch.

Address(es): ETHERSW.MODE_CONFIG A00C 0024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	STATS RESET	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b31	STATSRESET	Statistics Counter Reset	Resets the statistics counter in the Ethernet switch (A00C 0300h to A00C 0324h). Writing 1 to this bit resets the counter. Afterwards, this bit is cleared to 0.	R/W

29.2.2.8 VLAN Tag ID Register (VLAN_TAG_ID)

This register is used to set a VLAN tag ID to identify a VLAN tagged frame. In valid IEEE802.1Q, a VLAN tag ID is defined as 8100h. The value should not be changed since the value after reset of the register is 8100h.

Address(es): ETHERSW.VLAN_TAG_ID A00C 0034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VLANTAGID															
Value after reset:	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	VLANTAGID	ID Identification Setting	Identify a VLAN tag ID. In valid IEEE802.1Q, VLAN tag ID is defined as 8100h.The value should not be changed from the value after reset.	R/W
b31 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.9 Output Queue Management Status Register (OQMGR_STATUS)

This register is used to indicate the status of output queue of the Ethernet switch.
Writing a given value to the register clears latched bits (bit 1 and bit 3).

Address(es): ETHERSW.OQMGR_STATUS A00C 0080h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CELLAVILABLE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	DEQUEGRANT	—	—	MEMFULL_LT	MEMFULL	NOCELL	BUSYINIT
Value after reset:	0	0	0	0	0	0	0	0	0	1	0	0	1	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	BUSYINIT	Memory Initialization Status	When set to 1, the memory controller in the Ethernet switch indicates the initialization status. This bit is set to 0 when it is asserted after a reset and the initialization of the memory controller is complete. The switch must not be enabled before the initialization of the memory controller has been completed.	R/W
b1	NOCELL	Memory Cell Remaining Status	This bit is set to 1 when no cell remains in the output queue. This bit is always set to 1 after a reset. When initialization is complete, (the BUSYINIT bit is 0), write a given value to the register to clear this bit. When this bit is set to 1 during operation, this is a fatal error. As long as the hardware is in normal operation, this bit is never set to 1. If happens, for any reasons, reset this bit and set a larger value to the output queue minimum memory register (QMGR_MINCELLS).	R/W
b2	MEMFULL	Memory Full Status	Indicates whether or not the memory is currently full. This bit is set to 1 when the number of available memory is less than the minimum memory size specified in QMGR_MINCELLS. This is not an error, unlike the NOCELL, the memory controller operates normally. To avoid an overflow of the memory, the switch stops the operation of the input port.	R/W
b3	MEMFULL_LT	MEMFULL Result	Indicates the latched value of the MEMFULL result. Even when MEMFULL is cleared 0 from 1, the MEMFULL_LT bit retains 1. The bit is cleared when any value is written to the register.	R/W
b5, b4	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b6	DEQUEGRANT	De-queue Status Indication	Indicates whether or not any input is de-queued. This bit is set to 1 generally, but set to 0 once the memory is full.	R/W
b15 to b7	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b31 to b16	CELLAVILABLE	Memory Cell Number Indication	Indicates the number of currently available cells in real-time.	R/W

29.2.2.10 Output Queue Minimum Memory Register (QMGR_MINCELLS)

This register is used to set the minimum ensure value of memory for output queue for the Ethernet switch and must be set with a margin to avoid memory underflow.

Address(es): ETHERSW.QMGR_MINCELLS A00C 0084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	MINCELLS				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	MINCELLS	Available Cell Threshold Setting	Set the threshold of available cells of the output queue memory. The switch stops input port operation and discards received frames when available cells becomes less than this value. The value should be chosen to give enough margin of at least 1 full-sized frame. A memory underflow due to a too low threshold is a fatal error and requires a reset. 1 cell consists of 256 bytes and the value after reset is 9 (2.3 Kbytes).	R/W
b31 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.11 Output Queue Minimum Memory Statistics Register (QMGR_ST_MINCELLS)

This register is used to indicate the minimum number of free cells in the memory for output queue of the Ethernet switch.

Address(es): ETHERSW.QMGR_ST_MINCELLS A00C 0088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	STMINCELLS				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	STMINCELLS	Minimum Free Cell Indication	Indicate the lowest number of free cells reached in the memory during operation after this register is cleared. Writing a given value resets the register value to 0.	R/W
b31 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.12 Output Queue Congestion Status Register (QMGR_CGS_STAT)

This register is used to indicate the congestion status (concentration of access, etc.) of each port of the Ethernet switch.

Address(es): ETHERSW.QMGR_CGS_STAT A00C 008Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	P2CGS	P1CGS	P0CGS
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	P0CGS	Port 0 Congestion Status Indication	Congestion status of the queues of port 0 0: Vacancy 1: Congested	R
b1	P1CGS	Port 1 Congestion Status Indication	Congestion status of the queues of port 1 0: Vacancy 1: Congested	R
b2	P2CGS	Internal Interface Port Congestion Status Indication	Congestion status of the queues of the internal interface port (port 2) 0: Vacancy 1: Congested	R
b31 to b3	—	Reserved	When read, an undefined value is read.	R

29.2.2.13 Internal Queue Interface Status Register (QMGR_IFACE_STAT)

This register is used to indicate the RX and TX FIFO status of each port of the Ethernet switch and to indicate the result of internal interface handshaking.

Address(es): ETHERSW.QMGR_IFACE_STAT A00C 0090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	P2RXFIFOAV	P1RXFIFOAV	P0RXFIFOAV
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	P2TXFIFOST	P1TXFIFOST	P0TXFIFOST
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	1	1	1

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	P0TXFIFOST	Port 0 TX FIFO Status	Indicates whether or not TX FIFO of port 0 is READY 0: Not READY 1: READY	R
b1	P1TXFIFOST	Port 1 TX FIFO Status	Indicates whether or not TX FIFO of port 1 is READY 0: Not READY 1: READY	R
b2	P2TXFIFOST	Internal Interface TX FIFOStatus	Indicates whether or not TX FIFO of the internal interface port (port 2) is READY 0: Not READY 1: READY	R
b15 to b3	—	Reserved	When read, an undefined value is read.	R
b16	P0RXFIFOAV	Port 0 RX FIFO Status	Indicates whether RX FIFO data of port 0 is available 0: Not available 1: Available	R
b17	P1RXFIFOAV	Port 1RX FIFO Status	Indicates whether RX FIFO data of port 1 is available 0: Not available 1: Available	R
b18	P2RXFIFOAV	Internal Interface RX FIFO Status	Indicates whether RX FIFO data of the internal interface port (port 2) is available 0: Not available 1: Available	R
b31 to b19	—	Reserved	When read, an undefined value is read.	R

29.2.2.14 Queue Weight Register (QMGR_WEIGHTS)

This register is used to define weights (priority levels) for the corresponding queues for all ports of the Ethernet switch. Each port has 4 queues and a weight can be set for each queue. The weight settings are common to all ports.
Setting the weights of all queues to 0 implements a strict priority scheme. In this case, queue 3 is the highest priority queue.
If you do not wish to use strict priority, set respective weights of 1, 2, 4, and 8 to queues 0, 1, 2, and 3.

Address(es): ETHERSW.QMGR_WEIGHTS A00C 0094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	QUEUE3					—	—	—	QUEUE2				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	QUEUE1					—	—	—	QUEUE0				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	QUEUE0	Queue0 Weight Setting	Set the weight of queue 0. The valid range is from 0 to 12 (although 5 bits are writable per queue).	R/W
b7 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b12 to b8	QUEUE1	Queue1 Weight Setting	Set the weight of queue 1. The valid range is from 0 to 12 (although 5 bits are writable per queue).	R/W
b15 to b13	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b20 to b16	QUEUE2	Queue2 Weight Setting	Set the weight of queue 2. The valid range is from 0 to 12 (although 5 bits are writable per queue).	R/W
b23 to b21	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b28 to b24	QUEUE3	Queue3 Weight Setting	Set the weight of queue 3. The valid range is from 0 to 12 (although 5 bits are writable per queue).	R/W
b31 to b29	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.2.15 VLAN Priority Register n (VLAN_PRIORITYn) (n = 0 to 2)

These registers are used to set priority of the VLAN tag of the input frames.
The Ethernet switch has an 8-entry programmable priority lookup table for each port. The priority included in the 3 high-order bits of the of the first octet of the VLAN tag is used as an index of the lookup table and can be remapped.
Note: The range of values that can be set is 0 to 3 respectively for each priority. Always write 0 to the third bit.

Address(es): ETHERSW.VLAN_PRIORITY0 A00C 0100h, ETHERSW.VLAN_PRIORITY1 A00C 0104h, ETHERSW.VLAN_PRIORITY2 A00C 0108h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	PRIORITY7			PRIORITY6			PRIORITY5	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PRIORITY5	PRIORITY4			PRIORITY3			PRIORITY2			PRIORITY1			PRIORITY0		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	PRIORITY0	Priority 0 Setting	Priority for priority 0 of VLAN tag of input frames	R/W
b5 to b3	PRIORITY1	Priority 1 Setting	Priority for priority 1 of VLAN tag of input frames	R/W
b8 to b6	PRIORITY2	Priority 2 Setting	Priority for priority 2 of VLAN tag of input frames	R/W
b11 to b9	PRIORITY3	Priority 3 Setting	Priority for priority 3 of VLAN tag of input frames	R/W
b14 to b12	PRIORITY4	Priority 4 Setting	Priority for priority 4 of VLAN tag of input frames	R/W
b17 to b15	PRIORITY5	Priority 5 Setting	Priority for priority 5 of VLAN tag of input frames	R/W
b20 to b18	PRIORITY6	Priority 6 Setting	Priority for priority 6 of VLAN tag of input frames	R/W
b23 to b21	PRIORITY7	Priority 7 Setting	Priority for priority 7 of VLAN tag of input frames	R/W
b31 to b24	—	Reserved	The read value is undefined. When writing, write 0.	R/W

n = 0 to 2
n = 0: port 0, n = 1: port 1, n = 2: internal interface port (port 2)

29.2.2.16 IP Priority Register n (IP_PRIORITYn) (n = 0 to 2)

Each port of the Ethernet switch has class of services (COS) tables for IPv4 and IPv6. In the COS table entries for IPv4, the frame's 6-bit DiffServ field is provided as an index to the lookup table and a 2-bit priority can be set. In the COS table entries for IPv6, the frame's 8-bit COS field is provided as an index to the lookup table and a 2-bit priority can be set. This register is used to make and refer to COS table settings by writing to the COS table or making the settings for reference to a priority level.

Address(es): ETHERSW.IP_PRIORITY0 A00C 0140h, ETHERSW.IP_PRIORITY1 A00C 0144h, ETHERSW.IP_PRIORITY2 A00C 0148h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	READ	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PRIORITY		IPV6SELECT	ADDRESS							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	ADDRESS	COS Table Address Specifying	Specify an address for the index of the COS table. The IPv4 priority table is 6 bits (64 entries) and the IPv6 table is 8 bits (256 entries).	R/W
b8	IPV6SELECT	IPv6 COS Table Selection	Indicates the selection of the IPv6 COS table. 0: The IPv4 table is accessed. The valid range of the ADDRESS bits is from 0 to 63. 1: The IPv6 table is accessed. The valid range of the ADDRESS bits is from 0 to 255.	R/W
b10, b9	PRIORITY	COS Table Priority	When writing, set the priority information to be written to the COS table. When read, the priority information written to the COS table can be read. The address index of the COS table to be read is the address of the last write operation.	R/W
b30 to b11	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b31	READ	COS Table Operation Switching	Switches write or read operation to the COS table. Write operation to the register: 0: Write the priority information to the COS table. 1: Does not write the priority information to the COS table. (unchanged) Read operation from the register: The priority information of the address of the last write operation is read from the table. Follow the procedure below to read the priority information from the COS table. • Perform writing (specification of the address to be read) while this bit being 1 and the IPV6SELECT and ADDRESS bits are set to the desired values. • Execute read operation.	R/W

n = 0 to 2
n = 0: port 0, n = 1: port 1, n = 2: internal interface port (port 2)

29.2.2.17 PRIORITY Configuration Register n (PRIORITY_CFGn) (n = 0 to 2)

This register is used to set each port how received frames are assigned according to the priority of the queues in the switch by using which priority in the frames.
When several types of the priority fields are enabled, priority reassignment is executed according to higher priority (IP priority (DiffServ/COS), VLAN priority, and default priority).

Address(es): ETHERSW.PRIORITY_CFG0 A00C 0180h, ETHERSW.PRIORITY_CFG1 A00C 0184h, ETHERSW.PRIORITY_CFG2 A00C 0188h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	DEFAULTPRI			—	—	IPEN	VLANEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	VLANEN	VLAN Priority Enable	Enables VLAN priority for a frame received on port n. 0: VLAN priority is not used. The priority field of the VLAN tag of a frame is ignored. 1: Priority in the switch is determined by using the priority field of the VLAN tag of a frame according to the VLAN_PRIORITYn setting for the port on which the frame was received.	R/W
b1	IPEN	IP Priority Enable	Enables IP priority for a frame received on port n. 0: IP priority is not used and IP DiffServ/COS fields of the frame are ignored. 1: Priority in the switch is determined by using the IP DiffServ/COS field according to the IP_PRIORITYn setting for the port on which the frame was received.	R/W
b3, b2	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b6 to b4	DEFAULTPRI	Default Priority Enable Setting	Set the default priority of a frame received on port n. When neither of the priorities is used, this priority is applied. The valid range is from 0 to 3 and always write 0 to the 3rd bit.	R/W
b31 to b7	—	Reserved	The read value is undefined. When writing, write 0.	R/W

n = 0 to 2
n = 0: port 0, n = 1: port 1, n = 2: internal interface port (port 2)

29.2.2.18 HUB Control Register (HUB_CONTROL)

This register is used to set the hub operation. High speed cut through will be possible by enabling the hub function.

Address(es): ETHERSW.HUB_CONTROL A00C 01C0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	HUBIPG				BROCAFILEN	DIR1TO0EN	DIR0TO1EN	HUBEN
Value after reset:	0	0	0	0	0	0	0	0	1	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HUBEN	Hub Enable	Enables or disables the hub. 0: Disabled 1: Enabled Note: When set to 0 and the HUB_FLT_MACnhi.FORCEFOW bit is disabled, the hub is reset. Note: Disabling the hub does not disable the forced forwarding that can be enabled within each individual HUB_FLT_MACnhi register.	R/W
b1	DIR0TO1EN	Port 0 Hub Forwarding Enable	Enables or disables a transfer from port 0 to port 1 by the hub. When enabled, all traffic received on port 0 is transferred to port 1 through the hub when the hub is active. 0: Disabled 1: Enabled	R/W
b2	DIR1TO0EN	Port 1 Hub Forwarding Enable	Enables or disables a transfer from port 1 to port 0 by the hub. When enabled, all traffic received from port 1 is transferred to port 0 through the hub when the hub is active. 0: Disabled 1: Enabled	R/W
b3	BROCAFILEN	Broadcast Filter Enable	Enables or disables broadcast filter. If set, the hub will not transfer any broadcast frames (should be set normally). 0: Disabled 1: Enabled	R/W
b7 to b4	HUBIPG	IPG Size Setting	Set the size of the Inter-Packet-Gap (number of octets) to be inserted between frames when the hub transmits frames consecutively. The gap value to be inserted must be given - 2. The default Ethernet IPG is 12 octets, resulting in a value of 10 set in this register. The valid value range is from 6 to 13. Note: The hub must be disabled if either of the ports operates in half-duplex mode.	R/W
b31 to b8	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Note: DIR1TO0EN and DIR0TO1EN can be enabled at the same time. Simultaneous transfers of both directions is possible.

29.2.2.19 HUB Frame Count Register (HUB_STATS)

This register is used to indicate the number of frames transferred through the hub from one port to another. The counter of the channel is cleared when transfer is disabled (bit DIR1TO0EN or DIR0TO1EN of register HUB_CONTROL is set to 0).

Address(es): ETHERSW.HUB_STATS A00C 01C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	NUM1TO0															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	NUM0TO1															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	NUM0TO1	Port 0 Transfer Frame Number Indication	Number of frames transferred through the hub from port 0 to port 1 (the HUB_CONTROL.DIR0TO1EN bit is 1).	R
b31 to b16	NUM1TO0	Port 1 Transfer Frame Number Indication	Number of frames forwarded through the hub from port 1 to port 0 (the HUB_CONTROL.DIR1TO0EN bit is 1).	R

29.2.2.20 MAC Address Low Register For Hub Input Filter (HUB_FLT_MACnlo) (n = 0 to 6)

This register is used to set MAC addresses to be filtered in the hub. The first 4 octets of the MAC address are set to the HUB_FLT_MACnlo register and the remaining 2 octets are set to the HUB_FLT_MACnhi register. Up to 7 MAC addresses can be set. When any of the set MAC addresses matches with the destination address of the incoming frame, the frame is not transferred through the hub. MAC addresses of the unused register should be set to 0.

Address(es): ETHERSW.HUB_FLT_MAC0lo A00C 01C8h, ETHERSW.HUB_FLT_MAC1lo A00C 01D0h, ETHERSW.HUB_FLT_MAC2lo A00C 01D8h, ETHERSW.HUB_FLT_MAC3lo A00C 01E0h, ETHERSW.HUB_FLT_MAC4lo A00C 01E8h, ETHERSW.HUB_FLT_MAC5lo A00C 01F0h, ETHERSW.HUB_FLT_MAC6lo A00C 01F8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MACADD4n								MACADD3n							
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MACADD2n								MACADD1n							
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Note 1. n = 0 to 5: The value after reset is 0000 0000h.
n = 6: The value after reset is 006C 2101h. The destination address of the beacon frame is set for the value after reset. The beacon frame destination address must be held in the register when the DLR function is used.

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MACADD1n	MAC Address n First Byte Setting	Set the 1st byte of MAC address n	R/W
b15 to b8	MACADD2n	MAC Address n Second Byte Setting	Set the 2nd byte of MAC address n	R/W
b23 to b16	MACADD3n	MAC Address n Third Byte Setting	Set the 3rd byte of MAC address n	R/W
b31 to b24	MACADD4n	MAC Address n Fourth Byte Setting	Set the 4th byte of MAC address n	R/W

n = 0 to 6

29.2.2.21 MAC Address High Register For Hub Input Filter (HUB_FLT_MACnhi) (n = 0 to 6)

This register is used to set MAC addresses to be filtered in the hub. The first 4 octets of the MAC address are set to the HUB_FLT_MACnlo register and the remaining 2 octets are set to the HUB_FLT_MACnhi register. Up to 7 MAC addresses can be set. When any of the MAC addresses set matches with the destination address of the incoming frame, the frame is not transferred through the hub. MAC addresses of unused registers should be set to 0 and the MASKCOMP bit should be set to 0xFF.

Address(es): ETHERSW.HUB_FLT_MAC0hi A00C 01CCh, ETHERSW.HUB_FLT_MAC1hi A00C 01D4h, ETHERSW.HUB_FLT_MAC2hi A00C 01DCh, ETHERSW.HUB_FLT_MAC3hi A00C 01E4h, ETHERSW.HUB_FLT_MAC4hi A00C 01ECh, ETHERSW.HUB_FLT_MAC5hi A00C 01F4h, ETHERSW.HUB_FLT_MAC6hi A00C 01FCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b2b. 1	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	FORCE FOW	MASKCOMP							
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MACADD6n								MACADD5n							
Value after reset:	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1	*1

Note 1. n = 0 to 5: The value after reset is 0000 0000h.
n = 6: The value after reset is 01FF 0100h. The destination address of the beacon frame and enabling of forced forwarding are set for the value after reset. The beacon frame destination address must be held in the register when the DLR function is used.

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MACADD5n	MAC Address n Fifth Byte Setting	Set the 5th byte of MAC address n	R/W
b15 to b8	MACADD6n	MAC Address n Sixth Byte Setting	Set the 6th byte of MAC address n Bits of this field that correspond to bits of MASKCOMP for which the setting is 0 must also be set to 0.	R/W
b23 to b16	MASKCOMP	MAC Address Last Byte Mask Setting	The last byte of the MAC address (6th byte) can be masked and filtered in bit units. Of these 8 bits, only the bits set to 1 are compared in the case of filtering. The bits set to 0 are not compared. The logical AND of the last byte of received MAC addresses and these bits is taken and the result is compared with the value of the MACADD6n bits. Thus, the setting of MACADD6n bits corresponding to zero-valued bits of the mask setting should be 0.	R/W
b24	FORCEFOW	Forced Forward Setting	Enables or disables forced forwarding. 0: Disabled 1: Enabled When enabled, a frame whose MAC address matches is not filtered, and transferred through the hub. This frame is not transferred to the switch. The switch does not receive the frame because the frame is forcibly forwarded before being handled in the MAC in the switch. The DLR module will still be able to receive the frame. Forced forwarding is enabled even when the hub function is disabled (the HUB_CONTROL.HUBEN bit is set to 0).	R/W
b31 to b25	—	Reserved	The read value is undefined. When writing, write 0.	R/W

n = 0 to 6

29.2.2.22 Switch Statistics Registers

This LSI stores statistics of the frame to be processed by the Ethernet switch in the following registers.
All registers are 32-bit, read only and the value after reset is 0000 0000h.

Address	Symbol	Description
A00C 0300h	TOTAL_BYT_FRM	Total number of incoming frames processed and not discarded in bytes. (Sum of bytes of frames counted in TOTAL_FRM)
A00C 0304h	TOTAL_BYT_DISC	Total number of incoming frames processed but discarded in the switch in bytes. (Sum of bytes of frames counted in TOTAL_DISC)
A00C 0308h	TOTAL_FRM	Total number of incoming frames processed and not discarded.
A00C 030Ch	TOTAL_DISC	Total number of incoming frames processed but discarded in the switch.
A00C 0310h + 0008h*n	ODISCn	Port n outgoing frames discarded due to output queue congestion.
A00C 0314h + 0008h*n	IDISC_BLOCKEDn	Port n incoming frames discarded (after learning) as port is configured in blocking mode.

n = 0 to 2
n = 0: port 0, n = 1: port 1, n = 2: internal interface port (port 2)

29.2.3 Learning Interface Registers

Source addresses that the switch has learned and port information can be obtained through the learning interface to build a look-up table. The information can be obtained through two registers, but register LRN_REC_A must be read first, followed by a read to register LRN_REC_B.
After accessing register LRN_REC_B, the next learning entry, if available, is presented in registers LRN_REC_A and LRN_REC_B by FIFO.

29.2.3.1 Learning Record A Register (LRN_REC_A)

Address(es): ETHERSW.LRN_REC_A A00C 0500h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SRCADD4								SRCADD3							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRCADD2								SRCADD1							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SRCADD1	Source MAC Address First Octet Indication	Indicate the 1st octet of source MAC address.	R
b15 to b8	SRCADD2	Source MAC Address Second Octet Indication	Indicate the 2nd octet of source MAC address.	R
b23 to b16	SRCADD3	Source MAC Address Third Octet Indication	Indicate the 3rd octet of source MAC address.	R
b31 to b24	SRCADD4	Source MAC Address Fourth Octet Indication	Indicate the 4th octet of source MAC address.	R

29.2.3.2 Learning Record B Register (LRN_REC_B)

Address(es): ETHERSW.LRN_REC_B A00C 0504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	PORT				HASH							
Value after reset:	x	x	x	x	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRCADD6								SRCADD5							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SRCADD5	Source MAC Address Fifth Octet Indication	Indicate the 5th octet of the source MAC address.	R
b15 to b8	SRCADD6	Source MAC Address Sixth Octet Indication	Indicate the 6th octet of the source MAC address.	R
b23 to b16	HASH	Source MAC Address Hash Code Indication	Indicate hash code for the source MAC address.	R
b27 to b24	PORT	Port Number Indication	Indicate port number.	R
b31 to b28	—	Reserved	When read, an undefined value is read.	R

29.2.3.3 Learning Data Status Register (LRN_STATUS)

This register is used to indicate whether the learning data in register LRN_REC_A and register LRN_REC_B are valid.

Address(es): ETHERSW.LRN_STATUS A00C 0508h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LERNAVAL
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	LERNAVAL	Learning Data Status	Indicates learning data status. 0: Invalid 1: Valid	R
b31 to b1	—	Reserved	When read, an undefined value is read.	R

29.2.3.4 Address Table (ADR_TABLE)

The address table consists of blocks of 256 entries and each block contains 8 records which include 64-bit information. The 64-bit length record includes 48-bit MAC addresses and information necessary for transfer information as well as priority or time stamp information. The start address of such an 8-entry block is defined by the hash code derived from the MAC address. For the details, see section 29.3.1.4, Layer 2 Look Up Engine, section (3), Address Table, and section 29.4.3, Address Table Setting.

29.2.4 MAC Port Registers

These registers are related to the MACs of port 0 and port 1 that share most of the registers (COMMAND_CONFIGn and registers except for statistics register). Read and write operation are possible with access to the address configured by each port. The shared registers are indicated as “shared” in the names.

29.2.4.1 Command Configure Register n (COMMAND_CONFIGn) (n = 0, 1)

This register is used to configure and reset the MAC.

Address(es): ETHERSW.COMMAND_CONFIG0 A00C 8008h, ETHERSW.COMMAND_CONFIG1 A00C A008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CNTRESET	—	—	—	—	RXERRDISC	—	NOLGTHCHK	CNTRLREMEN	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	SWRESET	—	—	—	—	—	—	—	—	—	—	—	RXENA	TXENA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXENA	Transmission Enable	Enables or disables a MAC transmit path. 0: Disabled 1: Enabled This bit is cleared to 0 by a software reset.	R/W
b1	RXENA	Reception Enable	Enables or disables a MAC receive path. 0: Disabled 1: Enabled This bit is cleared to 0 by a software reset.	R/W
b3, b2	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b4	—	Reserved	The read value is undefined. When writing, write 1.	R/W
b12 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b13	SWRESET	Software Reset	Self-clearing software reset command. When written with 1, transmission and reception by MAC are disabled and the reception buffer is cleared. After software reset sequence is complete, this bit is automatically cleared to 0. Note: The bit is cleared to 0 only when the clock on the line of both MACs are supplied. When the clock on the line is not supplied, clear this bit by writing 0.	R/W
b22 to b14	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b23	CNTRLREMEN	Control Frame Enable	Enables or disables MAC control frames. 0: MAC Control frames with any Opcode other than 0001h are discarded. 1: MAC Control frames with any Opcode other than 0001h are received and transferred to other port.	R/W
b24	NOLGTHCHK	Payload Length Check Setting	Enables or disables payload length checking. 0: Enabled (debug) 1: Disabled Note: Always write 1 for this LSI.	R/W
b25	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b26	RXERRDISC	Reception Error Frame Discard Setting	Enables or disables receive error frame discard 0: Error frames are transferred to other port when RX_ER is asserted. (debug) 1: Any frame received with an error is discarded in the Core and not transferred to other port. Note: Always write 1 for this LSI.	R/W
b30 to b27	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b31	CNTRESET	Counter Reset	Self-clearing counter reset command When written with 1, the statistic counters are all set to 0. Afterwards, the bit is automatically cleared to 0. Note: This register is not shared between MAC0 and MAC1. However, this bit is an exception. Writing 1 to the bit through the MAC0 or MAC1 register will clear both MAC statistics.	R/W

n = 0, 1
n = 0: MAC port 0, n = 1: MAC port 1

29.2.4.2 Maximum Frame Length Register n (FRM_LENGTHn) (Shared) (n = 0, 1)

This register is used to set maximum frame length and to check frame length in the MAC reception circuit. The value after reset is set to 1522 allowing frames with a single VLAN tag. The value can be set to around 1536 to be more flexible for the tag. The allowed maximum is 1700.

Address(es): ETHERSW.FRM_LENGTH0 A00C 8014h, ETHERSW.FRM_LENGTH1 A00C A014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FRMLEN													
Value after reset:	0	0	0	0	0	1	0	1	1	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	FRMLEN	Maximum Frame Length Setting	Set maximum frame length.	R/W
b31 to b14	—	Reserved	The read value is undefined. When writing, write 0.	R/W

n = 0, 1
n = 0: MAC port 0, n = 1: MAC port 1

29.2.4.3 FIFO Buffer Threshold Register n (Shared) (n = 0, 1)

This register is used to configure the threshold of the FIFO buffer of the MAC and to manage overflow and underflow. It is not necessary to change from the value after reset basically.

Address	Symbol	Initial Value	R/W	Description
A00C 801Ch + 2000h*n	RX_SECTION_EMPTYn	0000 0000h	R	Threshold to indicate that the reception buffer is almost full. Reaching this is typically used as a trigger for transmitting a pause frame. Generation does not proceed when the setting is 0. The value cannot be changed from 0 in this LSI.
A00C 8020h + 2000h*n	RX_SECTION_FULLn	0000 0000h	RW	Threshold to indicate whether there are enough entries for a read from the reception buffer When set to 0, it enters to “Store and Forward”. Always set 0 in this LSI.
A00C 8024h + 2000h*n	TX_SECTION_EMPTYn	0000 0048h	RW	Threshold to indicate that the transmit FIFO is almost full.
A00C 8028h + 2000h*n	TX_SECTION_FULLn	0000 0014h	RW	Threshold to indicate whether there are enough entries for a read from the transmit FIFO.
A00C 802Ch + 2000h*n	RX_ALMOST_EMPTYn	0000 0008h	R	Threshold for unread entries before the reception buffer becomes empty. This is used to avoid any underflow of the FIFO. The value cannot be changed in this LSI.
A00C 8030h + 2000h*n	RX_ALMOST_FULLn	0000 0005h	R	Threshold for unread entries before the reception buffer becomes empty. This is used to avoid an overflow of the FIFO. The value cannot be changed in this LSI.
A00C 8034h + 2000h*n	TX_ALMOST_EMPTYn	0000 0004h	R	Threshold for unread entries before the transmit FIFO becomes empty. This is used to avoid an underflow of the FIFO. The value cannot be changed in this LSI.
A00C 8038h + 2000h*n	TX_ALMOST_FULLn	0000 0010h	R	Threshold for unread entries before the transmit FIFO becomes empty. This is used to avoid an overflow of the FIFO. The value cannot be changed in this LSI.

n = 0, 1
n = 0: MAC port 0, n = 1: MAC port 1

29.2.4.4 MAC Status Register n (MAC_STATUSn) (Shared) (n = 0, 1)

This register is used to indicate communication settings of the MAC.

Address(es): ETHERSW.MAC_STATUS0 A00C 8058h, ETHERSW.MAC_STATUS1 A00C A058h

n = 0: MAC port 0, n = 1: MAC port 1

29.2.4.6 MAC RX/TX Statistic Counters

This LSI stores statistics of the frame processed by the Ethernet switch in the register for each port.
The registers listed below are all 32-bit, read only and the value after reset is 0000 0000h.

(1) MAC RX Statistic Counters

Address	Symbol	Description
A00C 8100h + 2000h*n	etherStatsOctets_n	Total octets of the frames received on port n (including both normal and abnormal frames)
A00C 8104h + 2000h*n	OctetsOK_n	Total octets of the frames received on port n (normal frames only). A substitute of ifInOctets of the MIB counter.
A00C 8108h + 2000h*n	aAlignmentErrors_n	Number of frames received on port n when SDF is not detected even if RX_DV of the frame is deasserted
A00C 810Ch + 2000h*n	aPAUSEMACCtrlFrames_n	Number of normal pause frames received on port n
A00C 8110h + 2000h*n	FramesOK_n	Number of normal frames received on port n
A00C 8114h + 2000h*n	CRCErrors_n	Number of frames with abnormal CRC but normal length received on port n
A00C 8118h + 2000h*n	VLANOK_n	Number of normal frames with VLAN tag received on port n
A00C 811Ch + 2000h*n	ifInErrors_n	Number of frames received on port n with any of receive errors. • FIFO overflow errors • CRC errors • Payload length errors • Jabber and oversized errors • PHY errors (RX_ER asserted)
A00C 8120h + 2000h*n	ifInUcastPkts_n	Number of normal unicast frames received on port n
A00C 8124h + 2000h*n	ifInMulticastPkts_n	Number of normal multicast frames received on port n
A00C 8128h + 2000h*n	ifInBroadcastPkts_n	Number of normal broadcast frames received on port n
A00C 812Ch + 2000h*n	etherStatsDropEvents_n	Number of frames failed to receive on port n due to not enough space in FIFO
A00C 8130h + 2000h*n	etherStatsPkts_n	Total frames received on port n (normal and abnormal)
A00C 8134h + 2000h*n	etherStatsUndersizePkts_n	Number of frames with length of 64 bytes or less and normal CRC (excluding frames with length of 24 bytes or less)
A00C 8138h + 2000h*n	etherStatsPkts64Octets_n	Number of frames with length of 64 bytes received on port n
A00C 813Ch + 2000h*n	etherStatsPkts65to127Octets_n	Number of frames with length from 65 to 127 bytes received on port n
A00C 8140h + 2000h*n	etherStatsPkts128to255Octets_n	Number of frames with length from 128 to 255 bytes received on port n
A00C 8144h + 2000h*n	etherStatsPkts256to511Octets_n	Number of frames with length from 256 to 511 bytes received on port n
A00C 8148h + 2000h*n	etherStatsPkts512to1023Octets_n	Number of frames with length from 512 to 1023 bytes received on port n
A00C 814Ch + 2000h*n	etherStatsPkts1024to1518Octets_n	Number of frames with length from 1024 to 1518 bytes received on port n
A00C 8150h + 2000h*n	etherStatsPkts1519toMax_n	Number of frames with length from 1519 bytes to the value of the maximum frame length register (FRM_LENTGHn) received on port n
A00C 8154h + 2000h*n	etherStatsOversizePkts_n	Number of frames with length exceeding the value of the maximum frame length register (FRM_LENTGHn) and with normal CRC received on port n

Address	Symbol	Description
A00C 8158h + 2000h*n	etherStatsJabbers_n	Number of frames with length exceeding the value of the maximum frame length register (FRM_LENTGHn) and with abnormal CRC received on port n
A00C 815Ch + 2000h*n	etherStatsFragments_n	Number of frames with length of 64 bytes or less and abnormal CRC received on port n (excluding frames with length of 24 bytes or less) DLR beacon frames are also counted.
A00C 8160h + 2000h*n	aMACControlFramesReceived_n	Number of normal frames with type 0x8808 received on port n
A00C 8164h + 2000h*n	aFrameTooLong_n	Total frames with length exceeding the value of the maximum frame length register (FRM_LENTGHn) in received on port n (normal and abnormal)
A00C 816Ch + 2000h*n	StackedVLANOK_n	Number of normal frames with the stacked VLAN tag received on port n

n = 0, 1
n = 0: port 0, n = 1: port 1

(2) MAC TX Statistic Counters

Address	Symbol	Description
A00C 8180h + 2000h*n	TXetherStatsOctets_n	Total octets of the frames transmitted on port n (including both normal and abnormal frames)
A00C 8184h + 2000h*n	TxOctetsOK_n	Total octets of the frames transmitted on port n (normal frames only)
A00C 818Ch + 2000h*n	TXaPAUSEMACCtrlFrames_n	Number of formal pause frames transmitted on port n
A00C 8190h + 2000h*n	TxFramesOK_n	Number of formal frames transmitted on port n
A00C 8194h + 2000h*n	TxCRCErrors_n	Number of frames with abnormal CRC but normal length transmitted on port n
A00C 8198h + 2000h*n	TxVLANOK_n	Number of formal frames with the VLAN tag transmitted on port n
A00C 819Ch + 2000h*n	ifOutErrors_n	Number of frames transmitted on port n with any of receive errors. • TX_ER • Frame length errors
A00C 81A0h + 2000h*n	ifUcastPkts_n	Number of normal unicast frames transmitted on port n
A00C 81A4h + 2000h*n	ifMulticastPkts_n	Number of normal multicast frames transmitted on port n
A00C 81A8h + 2000h*n	ifBroadcastPkts_n	Number of normal broadcast frames transmitted on port n
A00C 81ACh + 2000h*n	TXetherStatsDropEvents_n	Number of undersized frames transmitted on port n. Caused either by FIFO full or collisions during half- duplex communications.
A00C 81B0h + 2000h*n	TXetherStatsPkts_n	Total frames transmitted on port n (normal and abnormal)
A00C 81B4h + 2000h*n	TXetherStatsUndersizePkts_n	Number of frames with length of 64 bytes or less and normal CRC (rarely occurs)
A00C 81B8h + 2000h*n	TXetherStatsPkts64Octets_n	Number of frames with length of 64 bytes transmitted on port n
A00C 81BCh + 2000h*n	TXetherStatsPkts65to127Octets_n	Number of frames with length from 65 to 127 bytes transmitted on port n
A00C 81C0h + 2000h*n	TXetherStatsPkts128to255Octets_n	Number of frames with length from 128 to 255 bytes transmitted on port n
A00C 81C4h + 2000h*n	TXetherStatsPkts256to511Octets_n	Number of frames with length from 256 to 511 bytes transmitted on port n
A00C 81C8h + 2000h*n	TXetherStatsPkts512to1023Octets_n	Number of frames with length from 512 to 1023 bytes transmitted on port n

Address	Symbol	Description
A00C 81CCh + 2000h*n	TXetherStatsPkts1024to1518Octets_n	Number of frames with length from 1024 to 1518 bytes transmitted on port n
A00C 81D0h + 2000h*n	TXetherStatsPkts1519toMax_n	Number of frames with length from 1519 bytes to the value of maximum frame length register (FRM_LENTGHn)
A00C 81D4h + 2000h*n	TXetherStatsOversizePkts_n	Frames with length exceeding the value of the maximum frame length register (FRM_LENTGHn) and with normal CRC transmitted on port n
A00C 81D8h + 2000h*n	TXetherStatsJabbers_n	Frames with length exceeding the value of the maximum frame length register (FRM_LENTGHn) and with abnormal CRC transmitted on port n
A00C 81DCh + 2000h*n	TXetherStatsFragments_n	Frames with length 64 bytes or less transmitted on port n and marked erroneous
A00C 81E0h + 2000h*n	aMACControlFrames_n	Normal frames with type 0x8808 transmitted on port n
A00C 81E4h + 2000h*n	TXaFrameTooLong_n	Total frames with length exceeding the value of the maximum frame length register (FRM_LENTGHn) received on port n (normal and abnormal)
A00C 81ECh + 2000h*n	aMultipleCollisions_n	Number of frames successfully transmitted after multiple collisions occurred on port n Relevant only for half-duplex communications
A00C 81F0h + 2000h*n	aSingleCollisions_n	Number of frames successfully transmitted after one collision occurred on port n Relevant only for half-duplex communications
A00C 81F4h + 2000h*n	aLateCollisions_n	Number of frames sent in error due to late collisions on port n Relevant only for half-duplex communications
A00C 81F8h + 2000h*n	aExcessCollisions_n	Number of frames discarded due to excessive collisions (16 unsuccessful transmissions) on port n Relevant only for half-duplex communications

n = 0, 1
n = 0: port 0, n = 1: port 1

29.2.5 Timer Module Registers

The Ethernet switch incorporates a programmable timer module that is used for all timestamping functions. The timer module registers are used to indicate the settings and status.

29.2.5.1 Timer Module Configuration Register (TSM_CONFIG)

This register is used to control interrupt generation due to any event occurred during use of the timer functions.

Address(es): ETHERSW.TSM_CONFIG A00C C004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	IRQTXENAP1	IRQTXENAP0	—	—	—	—	—	—	—	IRQTEST	IRQTIMOVER	IRQEVTPERD	IRQEVTOFF	IRQENA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IRQENA	Timer Interrupt setting	Enables or disables an timer interrupt. No interrupt is generated unless this bit is set to 1 even when other bits are set to 1. 0: Disabled 1: Enabled	R/W
b1	IRQEVTOFF	Offset Correction Complete Interrupt Setting	Controls interrupt generation when timer offset correction is complete. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b2	IRQEVTPERD	ns Timer Interrupt Setting	Controls interrupt generation when ns timer reaches 1 second. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b3	IRQTIMOVER	Overflow Interrupt Setting	Controls interrupt generation when timer overflows. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b4	IRQTEST	Interrupt Setting for Test	Controls interrupt generation for software testing. 0: Normal operation 1: Interrupt is generated at the same timing of a write operation.	R/W
b11 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b12	IRQTXENAP0	Port 0 Transmit Timestamp Capture Interrupt Setting	Enables or disables transmit timestamp capture interrupt of port 0 0: Disabled 1: Enabled (interrupt is generated) When set, an interrupt is generated when the port's transmit timestamp register has stored a new timestamp.	R/W
b13	IRQTXENAP1	Port 1 Transmit Timestamp Capture Interrupt Setting	Enables or disables an interrupt due to transmit timestamp capture of port 1 0: Disabled 1: Enabled (interrupt is generated) When set, an interrupt is generated when the port's transmit timestamp register has stored a new timestamp.	R/W
b31 to b14	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.5.2 Interrupt Status/ACK Register (TSM_IRQ_STAT_ACK)

This register is used to check status of the interrupt by timer.
Reading the register can check the interrupt status/acknowledge. Interrupt generation is indicated by 1 while no interrupt generation by 0.
Writing 1 to the register clears the interrupt as well as the bit value.

Address(es): ETHERSW.TSM_IRQ_STAT_ACK A00C C008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	IRQTXP1	IRQTXP0	—	—	—	—	—	—	—	IRQTEST	IRQTIMOVER	IRQEVTPERD	IRQEVTOFF	IRQENA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IRQENA	Timer Interrupt Status	Indicates interrupt generation.	R/W
b1	IRQEVTOFF	Offset Addition Interrupt Status	Indicates interrupt generation due to timer offset addition	R/W
b2	IRQEVTPERD	ns Timer Interrupt Status	Indicates interrupt generation when ns timer reaches 1 second.	R/W
b3	IRQTIMOVER	Overflow Interrupt Status	Indicates overflow interrupt generation.	R/W
b4	IRQTEST	Interrupt Status for Test	Indicates interrupt generation for software testing.	R/W
b11 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b12	IRQTXP0	Port 0 Transmit Timestamp Capture Interrupt Status	Indicates interrupt generation of transmit timestamp capture of port 0	R/W
b13	IRQTXP1	Port 1 Transmit Timestamp Capture Interrupt Status	Indicates interrupt generation of transmit timestamp capture of port 1	R/W
b31 to b14	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.5.3 Port Timestamp Control/Status Register (PORTn_CTRL) (n = 0, 1)

This register is used to indicate the storage method of the timestamp acquired on port n to the register and status of the stored timestamp.

Address(es): ETHERSW.PORT0_CTRL A00C C020h, ETHERSW.PORT1_CTRL A00C C028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TSKEEP	TSOVR	TSVALID
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSVALID	Timestamp Status	Indicates the status of stored timestamp. 0: Timestamp is invalid. 1: Timestamp is valid. Writing to the register (with any value) clears the bit.	R/W
b1	TSOVR	Timestamp Overwrite Status	Indicates that a newer timestamp has overwritten the last stored timestamp. 0: Timestamp is not overwritten. 1: Timestamp is overwritten. This bit is set to 1 when a valid timestamp is stored (TSVALID = 1) and another timestamp is received before the software read the value. Writing to the register (with any value) clears the bit. When the configuration bit TSKEEP is set, if a new timestamp is received while TSVALID is 1, this bit indicates that timestamp(s) are ignored.	R/W
b2	TSKEEP	Timestamp Operation Setting	Sets timestamp to be stored in the timestamp register upon reception of a new timestamp. 0: The stored timestamp is overwritten with the new one. 1: The last timestamp is retained. When set, the stored timestamp is retained and a new timestamp is ignored until software has processed the timestamp and the TSVALID bit becomes 0.	R/W
b31 to b3	—	Reserved	The read value is undefined. When writing, write 0.	R/W

n = 0, 1
n = 0: MAC port 0, n = 1: MAC port 1

29.2.5.4 Port Timestamp Register (PORTn_TIME) (n = 0, 1)

This register is used to store time stamps obtained on port n.

Address(es): ETHERSW.PORT0_TIME A00C C024h, ETHERSW.PORT1_TIME A00C C02Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TSREG															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TSREG															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TSREG	Timestamp Store	Timestamp acquired on port n	R

n = 0, 1
n = 0: MAC port 0, n = 1: MAC port 1

29.2.5.5 Timer Control Register (ATIME_CTRL)

This register is used to set timer interrupt events and control timer.

Address(es): ETHERSW.ATIME_CTRL A00C C120h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PLUS1	CAPTR	—	RST	—	—	—	EVTPERIRST	EVTPERIENA	—	EVTOFFENA	—	TMENA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMENA	Timer Operation Control	0: Timer stops at the current value. 1: Timer starts counting.	R/W
b1	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b2	EVTOFFENA	Offset Correction Event Setting	Enables or disables an offset correction event. 0: Offset correction is not executed. 1: Offset correction is executed. When offset correction is complete, and if interrupt generation is set through the TSM_CONFIG register, an offset correction-event interrupt is generated and this bit is cleared to 0. For another offset correction, setting the bit to 1 is required. Note: The timer offset value should be set in advance.	R/W
b3	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b4	EVTPERIENA	Periodical Event Setting	Enables or disables periodical event in 1-second units. 0: No periodical event is generated. 1: A periodical event in 1-second units is generated. When interrupt generation is set through the TSM_CONFIG register, a periodical event due to switch interrupt is also generated. Note: The timer periodical value should be set in advance.	R/W
b5	EVTPERIRST	Periodical Event Timer Reset Setting	Sets a reset of the periodical event timer. 0: Timer counts up till wraparound. 1: Timer is reset to 0 when the count value of the timer reaches 1 second.	R/W
b8 to b6	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b9	RST	Timer Reset	Writing 1 resets the timer. This has no effect on the counter enable. When written with 1 while the counter is enabled, timer is reset to 0 and starts counting from the point.	R/W
b10	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b11	CAPTR	Timer Value Capture	Writing 1 captures the current timer value. When capture is complete, the bit is cleared, and time can be read from the ATIME and ATIME_SEC registers.	R/W
b12	PLUS1	Timer Counter Increment Setting	Writing 1 increments the timer counter by 1. When increment is complete, the bit is cleared.	R/W
b31 to b13	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Note 1. Bits 12, 11, and 9 are for command and can be used to activate the corresponding events directly. It is not necessary to retain any value of other bits set in the register when the command bit is set (i.e. read-modify-write is not required). The bits are read as 0 after the command has completed. If any of the command bits are non-zero, other bits are ignored.

Note 2. The value of timer can not be captured accurately while the timer is stopped. The captured value is invalid.

29.2.5.6 Timer Nanoseconds Register (ATIME)

This register is used to indicate the value of the nanosecond(ns)-timer and set time of the ns timer.

Address(es): ETHERSW.ATIME A00C C124h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMR	ns Timer Setting	Indicate setting value and read value of the timer. When writing to the register: set time to the timer. When read from the register: return the last captured value. To read the current value, a capture command of the ATIME_CTRL register (CAPTR bit) must be issued in advance. The value represents in nanoseconds (ns).	R/W

Note: The seconds value must be programmed into the ATIME_SEC register prior to writing into this register.

29.2.5.7 Timer Offset Correction Register (ATIME_OFFSET)

This register is used to set the value to be used to perform offset corrections. The offset can be corrected in two different methods and different setting values must be set for each method.
Write operation to the register starts offset correction. Thus, the value must be set to the ATIME_OFFS_CORR register in advance to select the correction method.

Address(es): ETHERSW.ATIME_OFFSET A00C C128h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	OFFSET															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OFFSET															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	OFFSET	Offset Correction Value Setting	Set values for performing offset corrections. • When register ATIME_OFFS_CORR is 0: Write the value to be offset. The value represents in nanoseconds. The written value is immediately added to the current timer value when this register is written. When a negative value is written, the value is subtracted. • When register ATIME_OFFS_CORR is not 0: Write the value that defines how many offset corrections will be performed. When written, correction starts. The value is not immediately added to the current timer value When offset correction is performed, the value of the register is decremented by 1. Offset correction and decrementation are repeated until it reaches 0. When it has reached 0, no more offset corrections is performed and the register then is reset to 0. The interval of the offset is specified by the ATIME_OFFS_CORR register while the offset value is specified by the ATIME_INC register.	R/W

29.2.5.8 Generate Timer Periodic Event Register (ATIME_EVT_PERIOD)

This register is used to set the periodical value for generating periodic events. The nanoseconds timer has reached this time, the periodical event occurs and the nanoseconds timer restarts. The value represents in nanoseconds (ns). The value after reset is 10^9 nanoseconds, representing 1 second.

Address(es): ETHERSW.ATIME_EVT_PERIOD A00C C12Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TIMPEREVET															
Value after reset:	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TIMPEREVET															
Value after reset:	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TIMPEREVET	Event Periodical Setting	Period of an periodical event. It is necessary to set 3B9A CA00h (1 sec).	R/W

Note: Cycle events is fixed to 1 second and can not be changed. Otherwise, the timer will not operate normally.

29.2.5.9 Timer Drift Correction Register (ATIME_CORR)

This register is used to set correction period to be applied for drift correction by using clock cycle count. The amount of correction is defined in the ATIME_INC register.

Address(es): ETHERSW.ATIME_CORR A00C C130h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	DRIFCORVAL														
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DRIFCORVAL															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b30 to b0	DRIFCORVAL	Drift Correction Period Setting	Period for drift correction. Set the value by using clock cycles (100 MHz (10 ns)). For example, a drift correction with 1 msec intervals, set 10^5 (0001 86A0h) (set a desirable value for correction interval according to the actual application).	R/W
b31	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Note: The correction value is the reciprocal of the ppm deviation between the master and slave oscillators. This value is given in clock cycles, not in nanoseconds.

29.2.5.10 Timer Increment Register (ATIME_INC)

This register is used to set the correction amount to be used for offset or drift correction.

Address(es): ETHERSW.ATIME_INC A00C C134h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	OFFSCORRINC						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	CORRINC							—	CLKPERD						
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b6 to b0	CLKPERD	Clock Cycle Setting	Clock cycle of the timestamping clock in nanoseconds. Always set 10 ns (001010b). The clock 100 MHz and no other value cannot be set. The timer will increment by this amount with every clock cycle.	R/W
b7	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b14 to b8	CORRINC	Clock Cycle Correction Amount Setting	Set correction amount for clock cycle for drift corrections. This value will be added for each correction cycle specified in register ATIME_CORR. Setting a value smaller than in the CLKPERD bit will slow down the timer. Setting a value larger than in the CLKPERD bit will speed up the timer.	R/W
b15	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b22 to b16	OFFSCORRINC	Offset Correction Amount Setting	Set correction amount for offset correction. This value will be added for each clock cycle specified in register ATIME_OFFS_CORR.	R/W
b31 to b23	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.5.11 Timer Second Register (ATIME_SEC)

This register is used to indicate the seconds timer value. The time of the seconds timer can be set and the captured time can be obtained. The seconds-timer is incremented when the nanoseconds timer has reached 10^9 nanoseconds.

Address(es): ETHERSW.ATIME_SEC A00C C138h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SECTIM															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SECTIM															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	SECTIM	Seconds Timer Setting	Indicate the setting value and read value of the seconds time. When writing to the register: set time to the timer. The register is not updated when written and the value is retained in the local register. Afterwards, the ATIME register is written, the value in the local register is acquired to the register. When read from the register: return the last captured value. To read the current value, the capture command of register ATIME_CTRL (CAPTR bit) must be issued in advance. The unit of the value is in seconds.	R/W

29.2.5.12 Timer Offset Correction Count Register (ATIME_OFFS_CORR)

This register is used to set the interval for offset correction.
It is used in combination with the ATIME_OFFSET register to distribute the time change over a longer time due to additional offsets. It avoids jumps in time and minimizes jitter during offset corrections.

Address(es): ETHERSW.ATIME_OFFS_CORR A00C C13Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	OFFCOR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OFFCOR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	OFFCOR	Offset Correction Interval Setting	Specify the interval of offset correction. The interval will be set with cycle count of a 100 MHz clock.	R/W

29.2.5.13 Timer Output Enable Register (SWTMEN)

This register is used to enable time synchronous timer pulse output (SYNCOUT signal).
This register can be read and written in 32-bit units.
Note: Always enable output after setting the timer output control registers below:
SWTMSTSEC, SWTMSTNS, SWTMPSEC, SWTMPNS, and SWTMWTH.

Address(es): ETHERSW.SWTMEN A00B F200h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	OUTEN
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	OUTEN	SYNCOUT Signal Output Setting	Enables output of the SYNCOUT signal. 0: Disabled 1: Enabled	R/W
b31 to b1	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.5.14 Timer Start Second Register (SWTMSTSEC)

This register is used to set start time of SYNCOUT output in seconds.

Address(es): ETHERSW.SWTMSTSEC A00B F204h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMSTSEC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMSTSEC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMSTSEC	SYNCOUT Signal Output Start Time Setting	Set the start time of SYNCOUT output in seconds.	R/W

29.2.5.15 Timer Start Nanosecond Register (SWTMSTNS)

This register is used to set start time of SYNCOUT output in nanoseconds.

Address(es): ETHERSW.SWTMSTNS A00B F208h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMSTNS															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMSTNS															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMSTNS	SYNCOUT Signal Output Start Time Setting	Set the start time of SYNCOUT output in nanoseconds.	R/W

29.2.5.16 Timer Period Second Register (SWTMPSEC)

This register is used to set the period of SYNCOUT output in seconds.

Address(es): ETHERSW.SWTMPSEC A00B F20Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMPSEC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMPSEC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMPSEC	SYNCOUT Signal Output Period Setting	Set the period of SYNCOUT output in seconds.	R/W

29.2.5.17 Timer Period Nanosecond Register (SWTMPNS)

This register is used to set the period of SYNCOUT output in nanoseconds. Set the value which is to define the cycle when used as a divisor of the value for one second specified in the ATIME_EVT_PERIOD register.

Note 1. Set this register before enabling SYNCOUT signal output.

Note 2. The value must be greater than or equal to 30 ns.

Address(es): ETHERSW.SWTMPNS A00B F210h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMPNS															
Value after reset:	0	0	1	1	1	0	1	1	1	0	0	1	1	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMPNS															
Value after reset:	1	1	0	0	1	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMPNS	SYNCOUT Signal Output Period Setting	Set the period of SYNCOUT output in nanoseconds. The value must be a multiple of 10 ns.	R/W

29.2.5.18 Timer Pulse Width Register (SWTMWTH)

This register is used to set the pulse width of SYNCOUT output in nanoseconds. When the SYNCOUT signal is used as an interrupt signal, do not change the value after reset. When the signal is used as an external signal, appropriate width must be specified.

Note 1. Always set this register before enabling SYNCOUT signal output.

Address(es): ETHERSW.SWTMWTH A00B F214h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMWTH															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TMWTH	SYNCOUT Signal Output Width Setting	Set the pulse width of SYNCOUT output in nanoseconds. The value must be a multiple of 10 ns. The SYNCOUT signal is fixed to 0 in case this register is set to 0h.	R/W
b31 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.5.19 Timer Latch Second Register (SWTMLATSEC)

This register is used to latch the IEEE1588 timer value in seconds when the SYNCOUT signal rises. The value is updated whenever the SYNCOUT signal rises.

Address(es): ETHERSW.SWTMLATSEC A00B F22Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMLATSEC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMLATSEC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMLATSEC	SEC Count Value Latching	Latch the time of rising of SYNCOUT in seconds.	R

29.2.5.20 Timer Latch Nanosecond Register (SWTMLATNS)

This register is used to latch the IEEE1588 timer value in nanoseconds when the SYNCOUT signal rises. The value is updated whenever the SYNCOUT signal rises.

Address(es): ETHERSW.SWTMLATNS A00B F230h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMLATNS															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMLATNS															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	TMLATNS	ns Count Value Latching	Latch the time of rising of SYNCOUT in nanoseconds.	R

29.2.6 DLR Module Registers

29.2.6.1 DLR Control Register (DLR_CONTROL)

This register is used to set the DLR.

Address(es): ETHERSW.DLR_CONTROL A00C E000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CYCMCLK								—	—	—	BECTIMOUT	—	—	—	DLRENA
Value after reset:	0	0	1	1	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DLRENA	DLR Setting	Enables or disables the DLR. 0: Disabled 1: Enabled	R/W
b3 to b1	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b4	BECTIMOUT	Beacon Frame Handling	Ignores the beacon frames with invalid timeout timer value. When timeout timer value not within the range of 200 microseconds to 500 milliseconds, the beacon frames will be ignored and parameters will not locally stored. Invalid timeout timer value will always be stored within register INV_TMOUT irrespective of the value of this bit. Ignored frames will be transferred through the hub normally. 0: Not ignored 1: Ignored	R/W
b7 to b5	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b15 to b8	CYCMCLK	Clock Count Setting	Set the number of cycles required for 1 microsecond. The DLR module of this LSI operates at 75 MHz, thus this register must be set to 4Bh. The value after reset needs to be changed.	R/W
b31 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.6.2 DLR Status Register (DLR_STATUS)

This register is used to indicate the state of the DLR link node.

Address(es): ETHERSW.DLR_STATUS A00C E004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	NETTOPGY								—	—	—	—	—	—	LINSTAP1	LINSTAP0
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	0*1	0*1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CURRSTA								—	—	—	—	—	—	BEAREV1	BEAREV0
Value after reset:	0	0	0	0	0	0	0	0	x	x	x	x	x	x	0	0

x: Undefined

Note 1. When released from the reset state, the latched values of the pin levels of the PHYLINK0 and PHYLINK1 pins are read.

Bit	Symbol	Bit Name	Description	R/W
b0	BEAREV0	Port 0 Beacon Frame Reception Status	Indicates that beacon frames are received from the active supervisor on port 0. 0: No beacon frame received 1: Beacon frame received	R
b1	BEAREV1	Port 1 Beacon Frame Reception Status	Indicates that beacon frames are received from the active supervisor on port 1 0: No beacon frame received 1: Beacon frame received	R
b7 to b2	—	Reserved	When read, an undefined value is read.	R
b15 to b8	CURRSTA	Local Node Status	Indicate current state of local node 0h: IDLE_STATE 1h: NORMAL_STATE 2h: FAULT_STATE Others: Unused	R
b16	LINSTAP0	Port 0 Link Status Indication	Indicates the link status of port 0. 0: Port 0 link is down 1: Port 0 link is up	R
b17	LINSTAP1	Port 1 Link Status Indication	Indicates the link status of port 1. 0: Port 1 link is down 1: Port 1 link is up	R
b23 to b18	—	Reserved	When read, an undefined value is read.	R
b31 to b24	NETTOPGY	Network Topology Indication	Indicate current network topology 0h: Linear topology: when local node is in IDLE state 1h: Ring topology: when local node is not in IDLE state Others: Unused	R

29.2.6.3 DLR Ethernet Type Register (DLR_ETH_TYP)

This register is used to set the Ethernet type for detecting the DLR frame. This value is compared with type field of a received frame to detect DLR frame.

Address(es): ETHERSW.DLR_ETH_TYP A00C E008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ETHTYPDLR															
Value after reset:	1	0	0	0	0	0	0	0	1	1	1	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ETHTYPDLR	Ethernet Type Setting	Specify the Ethernet type for DLR frame detection.	R/W
b31 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.6.4 DLR Interrupt Control Register (DLR_IRQ_CTRL)

This register is used to control interrupt generation due to the DLR.

Address(es): ETHERSW.DLR_IRQ_CTRL A00C E00Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ATOMICAND	ATOMICOR	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	IRQFRMDSP1	IRQFRMDSP0	IRQBECENA1	IRQBECENA0	IRQINVTMREN	IRQIPADDREN	IRQSUPIGENA	IRQLINKENA1	IRQLINKENA0	IRQSUPENA	IRQBECTOUT1	IRQBECTOUT0	IRQSTOPP1	IRQSTOPP0	IRQFLUENA	IRQCHNGENA
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IRQCHNGENA	State Change Interrupt Control	Controls interrupt generation when state change occurs for the local beacon-based DLR ring node. 0: No interrupt is generated. 1: Interrupt is generated. Note: For the interrupt service routine, the beacon frame parameters must be re-read first to clear the bit.	R/W
b1	IRQFLUENA	Learning Table Interrupt Control	Controls interrupt generation when local MAC addresses must be erased from the learning table 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b2	IRQSTOPP0	Port 0 Neighbor Check Timeout Interrupt Control	Controls interrupt generation when neighbor check timeout timer interrupt to port 0 needs to be stopped. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b3	IRQSTOPP1	Port 1 Neighbor Check Timeout Interrupt Control	Controls interrupt generation when neighbor check timeout timer interrupt to port 1 needs to be stopped. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b4	IRQBECTOUT0	Port 0 Beacon Timeout Interrupt Control	Controls interrupt generation when the timeout time for the beacon timeout timer on port 0 has elapsed. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b5	IRQBECTOUT1	Port 1 Beacon Timeout Interrupt Control	Controls interrupt generation when the timeout time for the beacon timeout timer on port 1 has elapsed. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b6	IRQSUPENA	Ring Supervisor Change Interrupt Control	Controls interrupt generation when the ring supervisor changes 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b7	IRQLINKENA0	Port 0 Link Change Interrupt Control	Controls interrupt generation when the link of port 0 changes 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b8	IRQLINKENA1	Port 1 Link Change Interrupt Control	Controls interrupt generation when the link of port 1 changes 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b9	IRQSUPIGENA	Beacon Frame Detection Interrupt Control	Controls interrupt generation when a beacon frame is detected from a ring supervisor with lower priority than that of the current ring supervisor or with a lower MAC address value in case the priority level is the same. 0: No interrupt is generated. 1: Interrupt is generated.	R/W

Bit	Symbol	Bit Name	Description	R/W
b10	IRQIPADDREN	IP Address Change Interrupt Control	Controls interrupt generation when the IP address in a beacon frame output from a ring supervisor changes 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b11	IRQINVTMREN	Beacon Timeout Timer Interrupt Control	Controls interrupt generation when a frame in which beacon timeout timer value is outside of the specified range is detected. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b12	IRQBECENA0	Port 0 Beacon Frame Detection Interrupt Control	Controls interrupt generation when a beacon frame is detected on port 0. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b13	IRQBECENA1	Port 1 Beacon Frame Detection Interrupt Control	Controls interrupt generation when a beacon frame is detected on port 1. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b14	IRQFRMDSP0	Port 0 Frame Discard Interrupt Control	Controls interrupt generation when a frame is discarded due to source address match with the local address on port 0. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b15	IRQFRMDSP1	Port 1 Frame Discard Interrupt Control	Controls interrupt generation when a frame is discarded due to source address match with the local address on port 1. 0: No interrupt is generated. 1: Interrupt is generated.	R/W
b29 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W
b30	ATOMICOR	Register Write OR Operation Setting	When writing to the register, the logical OR of the values for the bits corresponding to enable bits of this register and the value of this bit is taken and the result is written to the register. 0: Normal write operation 1: All bits are set to 1	R/W
b31	ATOMICAND	Register Write AND Operation Setting	When writing to the register, the logical AND of the values for the bits corresponding to enable bits of this register and the value of this bit is taken the result is written to the register. 0: All bits are cleared to 0. 1: Normal write operation	R/W

29.2.6.5 DLR Interrupt Status/ACK Register (DLR_IRQ_STAT_ACK)

This register is used to indicate the status of DLR interrupts.
The status can be checked by reading the register: 1 indicates that an event has occurred whereas 0 indicates that no event has occurred.
Writing 1 to the register clears the interrupt and the bit value.

Address(es): ETHERSW.DLR_IRQ_STAT_ACK A00C E010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FRMDISP1	FRMDISP0	BECFRAP1	BECFRAP0	INVTMR	IPCHANEVET	SUPIGNBEC	LINKSTAP1	LINKSTAP0	SUPRCHAG	BECTMRP1	BECTMRP0	STOPNBCHK1	STOPNBCHK0	FLUEVENT	STACHANGE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	STACHANGE	DLR Ring Node Status	Indicates that the state of local beacon-based DLR node has changed.	R/W
b1	FLUEVENT	Local MAC Address Event	Indicates that local MAC addresses need to be erased from the learning table.	R/W
b2	STOPNBCHK0	Port 0 Neighbor Check Timeout Timer Event	Indicates that the neighbor check timeout timer needs to be stopped on port 0.	R/W
b3	STOPNBCHK1	Port 1 Neighbor Check Timeout Timer Event	Indicates that the neighbor check timeout timer needs to be stopped on port 1.	R/W
b4	BECTMRP0	Port 0 Beacon Timeout Timer Status	Indicates that the timeout time for the beacon timeout timer on port 0 has elapsed.	R/W
b5	BECTMRP1	Port 1 Beacon Timeout Timer Status	Indicates that the timeout time for the beacon timeout timer on port 1 has elapsed.	R/W
b6	SUPRCHAG	Ring Supervisor Change Status	Indicates that when the ring supervisor has been changed.	R/W
b7	LINKSTAP0	Port 0 Link State Status	Indicates that the state of link has changed on port 0.	R/W
b8	LINKSTAP1	Port 1 Link State Status	Indicates that the state of link has changed on port 1.	R/W
b9	SUPIGNBEC	Beacon Frame Detection Indication	Indicates that a beacon frame has been detected from a supervisor with lower priority or with lower value of the MAC address in case the priority level is the same.	R/W
b10	IPCHANEVET	IP Address Change Indication	Indicates that the IP address in the beacon frame output from the ring supervisor has been changed.	R/W
b11	INVTMR	Beacon Timeout Timer Status	Indicates that the beacon timeout timer has detected a frame with a value outside of the specified range.	R/W
b12	BECFRAP0	Port 0 Beacon Frame Status	Indicates that the beacon frame has been detected on port 0.	R/W
b13	BECFRAP1	Port 1 Beacon Frame Status	Indicates that the beacon frame has been detected on port 1.	R/W
b14	FRMDISP0	Port 0 Frame Status	Indicates that a frame has been discarded due to source address match with the local address on port 0.	R/W
b15	FRMDISP1	Port 1 Frame Status	Indicates that a frame has been discarded due to source address match with the local address on port 1.	R/W
b31 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W

Note: When any event described above happens, the corresponding bit is latched to 1, regardless of the DLR_IRQ_CONTROL register setting.

29.2.6.6 DLR Local MAC Address Low Register (LOC_MAClo)

This register is used to specify the local MAC address to be used in loop filter. The first 4 octets of the local MAC address and the remaining 2 octets are set to the LOC_MAClo register and LOC_MAChi register respectively.

Address(es): ETHERSW.LOC_MAClo A00C E014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MACADD4								MACADD3							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MACADD2								MACADD1							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MACADD1	Local MAC Address First Byte Setting	Specify the 1st byte of local MAC address	R/W
b15 to b8	MACADD2	Local MAC Address Second Byte Setting	Specify the 2nd byte of local MAC address	R/W
b23 to b16	MACADD3	Local MAC Address Third Byte Setting	Specify the 3rd byte of local MAC address	R/W
b31 to b24	MACADD4	Local MAC Address Fourth Byte Setting	Specify the 4th byte of local MAC address	R/W

29.2.6.7 DLR Local Mac Address High Register (LOC_MAChi)

This register is used to specify the local MAC address to be used in the loop filter. The first 4 octets of the local MAC address and the remaining 2 octets are set to LOC_MAClo register and LOC_MAChi register respectively.

Address(es): ETHERSW.LOC_MAChi A00C E018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MACADD6								MACADD5							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MACADD5	Local MAC Address Fifth Byte Setting	Specify the 5th byte of local MAC address	R/W
b15 to b8	MACADD6	Local MAC Address Sixth Byte Setting	Specify the 6th byte of local MAC address	R/W
b31 to b16	—	Reserved	The read value is undefined. When writing, write 0.	R/W

29.2.6.8 DLR Supervisor MAC Address Low Register (SUPR_MAClo)

This register is used to indicate the first 4 octets of the active ring supervisor's MAC address extracted from the destination address field of the beacon frame.

Address(es): ETHERSW.SUPR_MAClo A00C E020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MACADD4								MACADD3							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MACADD2								MACADD1							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MACADD1	Active Ring Supervisor MAC Address First Byte Setting	Indicate the 1st byte of active ring supervisor's MAC address	R
b15 to b8	MACADD2	Active Ring Supervisor MAC Address Second Byte Setting	Indicate the 2nd byte of active ring supervisor's MAC address	R
b23 to b16	MACADD3	Active Ring Supervisor MAC Address Third Byte Setting	Indicate the 3rd byte of active ring supervisor's MAC address	R
b31 to b24	MACADD4	Active Ring Supervisor MAC Address Fourth Byte Setting	Indicate the 4th byte of active ring supervisor's MAC address	R

29.2.6.9 DLR Supervisor MAC Address High Register (SUPR_MAChi)

This register is used to indicate the remaining 2 octets of the active ring supervisor's MAC address extracted from the destination address field of the beacon frame as well as priority order of the supervisor.

Address(es): ETHERSW.SUPR_MAChi A00C E024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	SUPRPRE							
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	MACADD6								MACADD5							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	MACADD5	Active Ring Supervisor MAC Address Fifth Byte Setting	Indicate the 5th byte of active ring supervisor's MAC address	R
b15 to b8	MACADD6	Active Ring Supervisor MAC Address Sixth Byte Setting	Indicate the 6th byte of active ring supervisor's MAC address	R
b23 to b16	SUPRPRE	Ring Supervisor Priority Order Value Indication	Indicate priority of the ring supervisor.	R
b31 to b24	—	Reserved	When read, an undefined value is read.	R

29.2.6.10 DLR Ring Status/VLAN Register (STATE_VLAN)

This register is used to indicate the ring state of the DLR and VLAN ID that are extracted from the ring state field and VLAN control information field of the beacon frame.

Address(es): ETHERSW.STATE_VLAN A00C E028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	VLANCI															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	VLANVALID	RINGSTATE							
Value after reset:	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	RINGSTATE	DLR Ring Status	Indicate DLR ring state extracted from the ring state field of the beacon frame. 1h: RING_NORMAL_STATE 2h: RING_FAULT_STATE Others: Unused	R
b8	VLANVALID	VLAN Status	Indicates that VLAN is enabled. When asserted, the VLANCI contains valid VLAN ID. 0: Invalid 1: Valid	R
b15 to b9	—	Reserved	When read, an undefined value is read.	R
b31 to b16	VLANCI	VLAN Tag Control Field Indication	Indicate the 802.1Q VLAN tag control field extracted from the VLAN information field of the beacon frame. VLAN ID of the DLR is included.	R

29.2.6.11 DLR Beacon Timeout Register (BEC_TMOUT)

This register is used to indicate the beacon timeout timer value extracted from the beacon timeout field of the beacon frame.

Address(es): ETHERSW.BEC_TMOUT A00C E02Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BECTMOUT															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BECTMOUT															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	BECTMOUT	Beacon Timeout Timer Indication	Indicate beacon timeout timer value in microseconds (µs). Invalid timeout timer values will be not written to this register when bit 4 of register DLR_CONTROL (BECTIMOUT bit) is set to 1. State transition will not be considered. Normal expected value is in the range between 200 microseconds and 500 milliseconds. Typical value is 1960 microseconds.	R

29.2.6.12 DLR Beacon Interval Register (BEC_INTRVL)

This register is used to indicate the beacon frame interval extracted from the beacon interval field of the beacon frame.

Address(es): ETHERSW.BEC_INTRVL A00C E030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BECINTVAL															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BECINTVAL															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	BECINTVAL	Beacon Frame Interval Indication	Indicate beacon frame interval in microseconds (µ sec). Expected value is in the range between 100 microseconds and 100 milliseconds. Typical value is 400 microseconds.	R

29.2.6.13 DLR Supervisor IP Address Register (SUPR_IPADR)

This register is used to indicate the ring supervisor's IP address extracted from the source IP address field of the beacon frame.

Address(es): ETHERSW.SUPR_IPADR A00C E034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SPVIP															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPVIP															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	SPVIP	Ring Supervisor IP Address Indication	Indicate the ring supervisor's IP address A value of 0h is received when the supervisor has no IP address.	R

29.2.6.14 DLR Sub Type/Protocol Version Register (ETH_STYP_VER)

This register is used to indicate DLR message information extracted from the corresponding field in the beacon frame.

Address(es): ETHERSW.ETH_STYP_VER A00C E038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	SOURP							
Value after reset:	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DLRRINGVER								DLRRINGTPY							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	DLRRINGTPY	Ring Sub Type Indication	Indicate ring sub type of the DLR message. The value is expected to be 02h.	R
b15 to b8	DLRRINGVER	Ring Protocol Version Indication	Indicate ring protocol version of the DLR message. The value is expected to be 01h.	R
b23 to b16	SOURP	Transmit Source Port Indicator	Indicate transmit source port of the DLR message. The value is expected to be 00h.	R
b31 to b24	—	Reserved	When read, an undefined value is read.	R

29.2.6.15 DLR Beacon Timeout Timer Register (INV_TMOUT)

This register is used to indicate a timeout timer value outside of the specified range. When an invalid beacon frame with a timeout timer value outside of the range is received, such timeout value is extracted from the beacon frame and stored in the register.

Address(es): ETHERSW.INV_TMOUT A00C E03Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	INVBECTMOUT															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	INVBECTMOUT															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	INVBECTMOUT	Timeout Timer Value Indication	Indicate a beacon timeout timer value of the frame with invalid timeout timer value outside of the specified range in microseconds (μ sec). The target is outside of the valid range between 200 microseconds and 500 milliseconds. This register will be always overwritten whenever a new frame with an invalid value is received. The value contained in the register is valid when bit 11 of register IRQ_STAT_ACK is asserted to 1.	R

29.2.6.16 DLR Sequence ID Register (SEQ_ID)

This register is used to indicate the sequence ID of the beacon frame extracted from the sequence ID field of the beacon frame.

Address(es): ETHERSW.SEQ_ID A00C E040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SEQID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SEQID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	SEQID	Sequence ID Indication	Indicate the sequence ID of the last beacon frame received on port 0 or port 1. When a frame is ignored due to an invalid timeout timer value, the sequence ID of the ignored frame is not stored.	R

29.2.6.17 DLR MAC Statistics Counters

This LSI stores statistics of the beacon frame to be processed by the DLR module in the following registers.
All registers are 32-bit, read only and the initial value is 0000 0000h.

Address	Symbol	Description
A00C E060h + 0010h*n	RX_STATn	Number of beacon frames received on port n: The counter will increment with the beacon frames which match the destination address, Ether type, DLR frame type and CRC, and will not with type mismatch. The counter is cleared if the DLR module is disabled.
A00C E064h + 0010h*n	RX_ERR_STATn	Number of beacon frames received with CRC error on port n: The counter will increment with the beacon frames which match the destination address, Ether type, DLR frame type but with CRC error. The counter is cleared if the DLR module is disabled.
A00C E068h + 0010h*n	TX_STATn	Number of beacon frames forwarded through the hub from port n to port m: The counter is cleared if the DLR module is disabled.

n = 0, 1

n = 0: MAC port 0, n = 1: MAC port 1

m = 1 when n = 0, m = 0 when n = 1

29.3 Functional Description

29.3.1 Switching Engine

29.3.1.1 Overview

The Ethernet switch incorporates the following main functions:

- Input frame parsing and priority extraction
- Output port(s) judgment
- Frame queuing
- Output queue scheduling

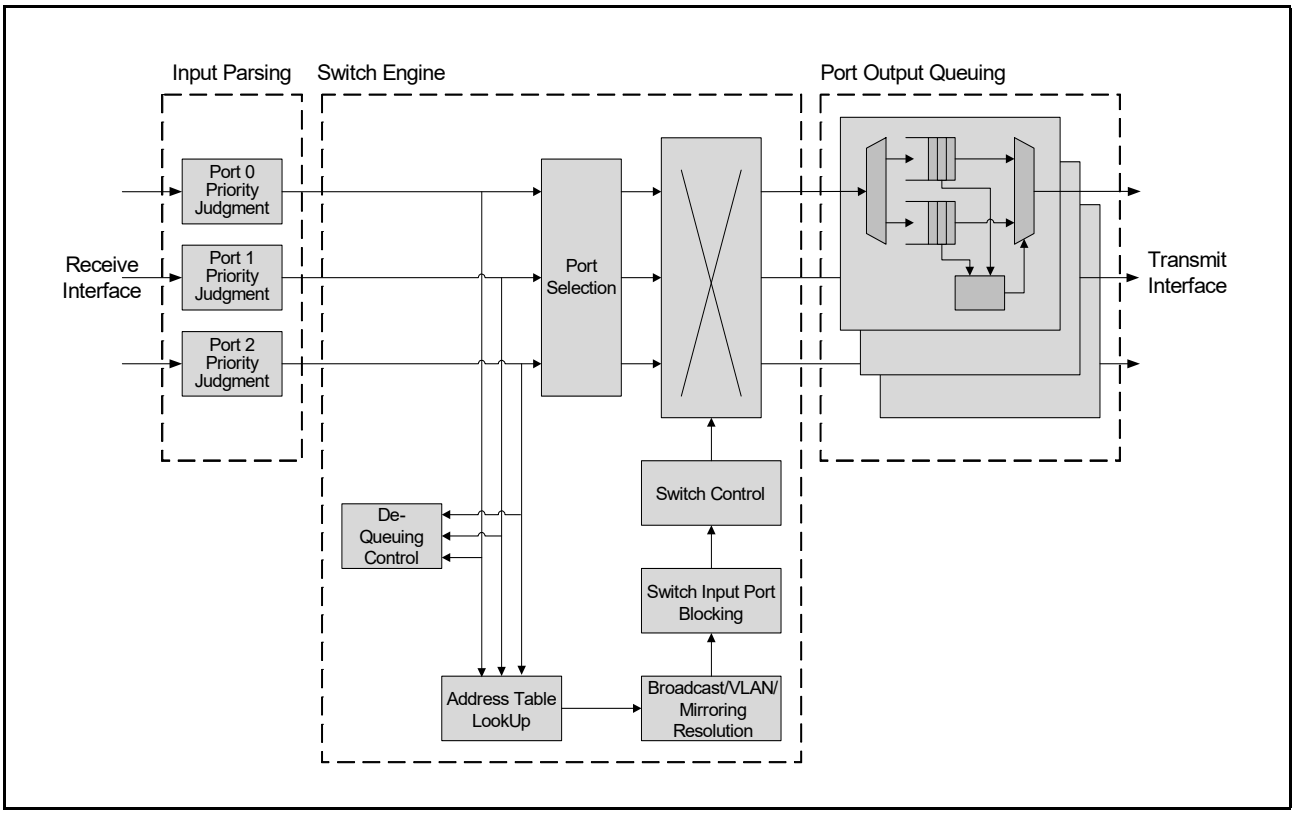

Figure 29.4 Switching Engine Overview

29.3.1.2 Frame Classification and Priority Processing

(1) Overview

When a frame is received on an input port, several pieces of information are extracted from the frame as the Ethernet MAC address, VLAN tag, and IP Headers to determine the frame type and classify the types.
The frame is classified with up to 8 different priorities (for VLAN) which can be remapped into any output priority. The frame is stored in the corresponding queue on the output port. If a frame is classified to a higher priority than available output queues of a port, it is stored into the queue with the highest priority.

(2) VLAN Priority Look-Up

On each port, an 8 entry programmable priority table is implemented. The registers VLAN_PRIORITYn contain the priority mapping for port n (n = 0 to 2). The function uses the 3-bit VLAN priority and maps it to the final priority.
The index in the mapping table consists of 3 bits (bit 7 to 5) of the first octet of the VLAN tag data with bit 5 as the LSB and bit 7 as the MSB.
Mapped value has 4 priorities. A value of 0 is interpreted as the lowest priority. A value of 3 is interpreted as the highest priority.

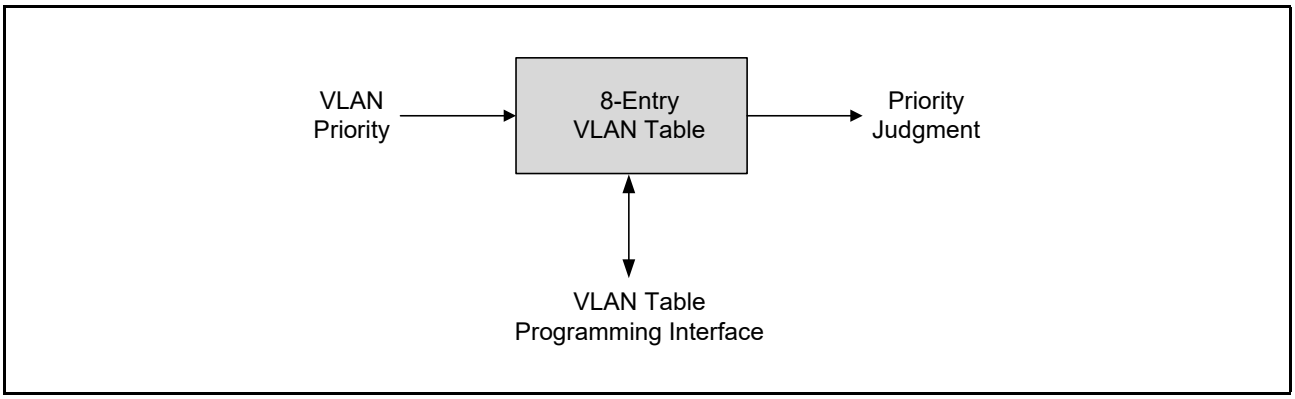

Figure 29.5 VLAN Priority Table Overview

(3) IPv4 and IPv6 Priority Look Up

The switch can classify priorities of both IPv4 and IPv6 frames: A 64-entry table is implemented per port to classify the IPv4 frames and a 256-entry table is implemented per port to classify IPv6 frames. The look-up table is set through the IP_PRIORITYn register.

On the IPv4 COS table entry, the 6-bit DiffServ field is provided as input and the table returns the 2-bit priority information.

On the IPv6 COS table entry, the 8-bit Class of Service field is provided as input and the table returns the 2-bit priority information.

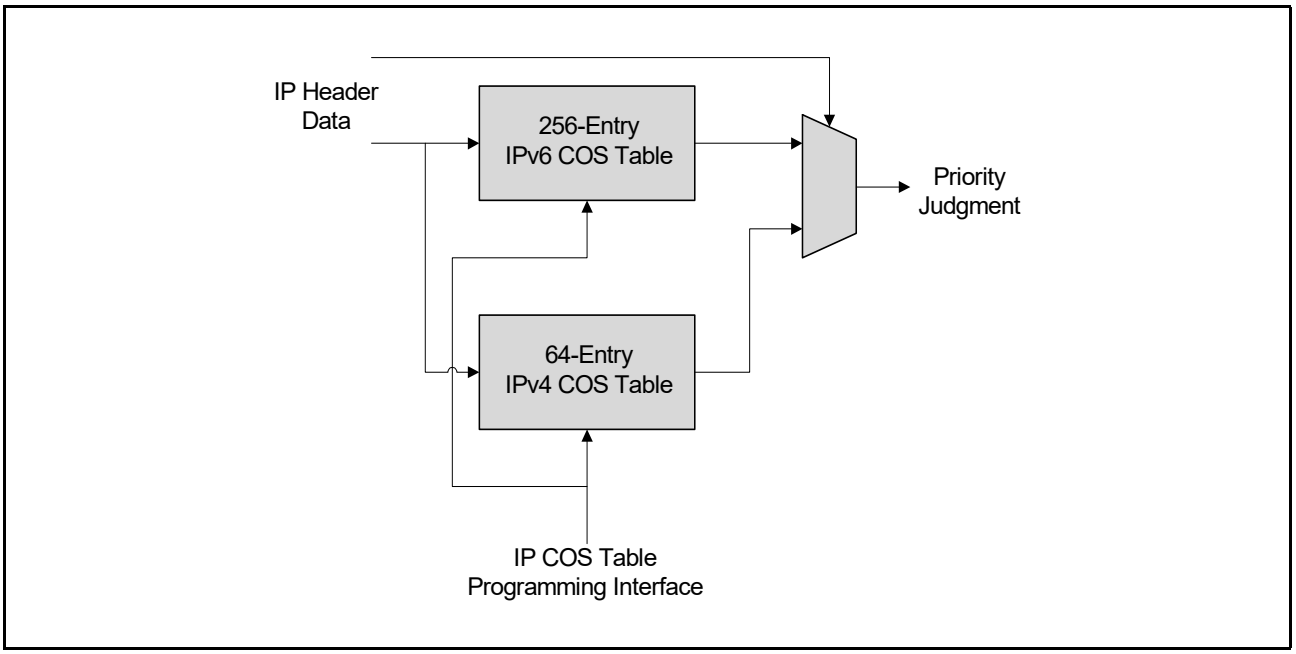

Figure 29.6 IP COS Tables Overview

(4) Priority Judgment

Priority can be judged on each port independently by programming registers PRIORITY_CFGn to enable or disable priority classification based on VLAN, IP, or MAC address.

The priority is judged according to the rules below depending on enabled classification method and fields found in the frame:

(1) When priority judgment by IP classification is enabled and an the IP header is found, priority is mapped by register IP_PRIORITYn.

(2) If not (1) above, when priority judgment by VLAN_PRIORITY is enabled and a VLAN tag is found, priority is mapped by register VLAN_PRIORITYn.

(3) If neither of (1) or (2) above, the default priority specified in register PRIORITY_CFG is used.

29.3.1.3 Input Port Selection

The port selection circuit constantly checks all input ports by polling for available data. If any data is available, a port is selected and frame data is read from the port. After one frame has been read, another port is selected, even if further data is available on the current port.
This means for the application on a port FIFO input interface (e.g MAC), that it is not allowed to perform consecutive frame transfers to the switch. Instead the application must wait for a new selection after one frame has been transferred.

29.3.1.4 Layer 2 Look Up Engine

(1) Overview

A hash code is calculated by using the frame destination MAC address. It is used as an entry (address) to a table, which contains MAC addresses, destination port number, and validity information for each hash value.
As one hash code value can represent multiple MAC address, the memory implements for each pointer, up to eight MAC address entries (8-entry block), which are searched linearly.

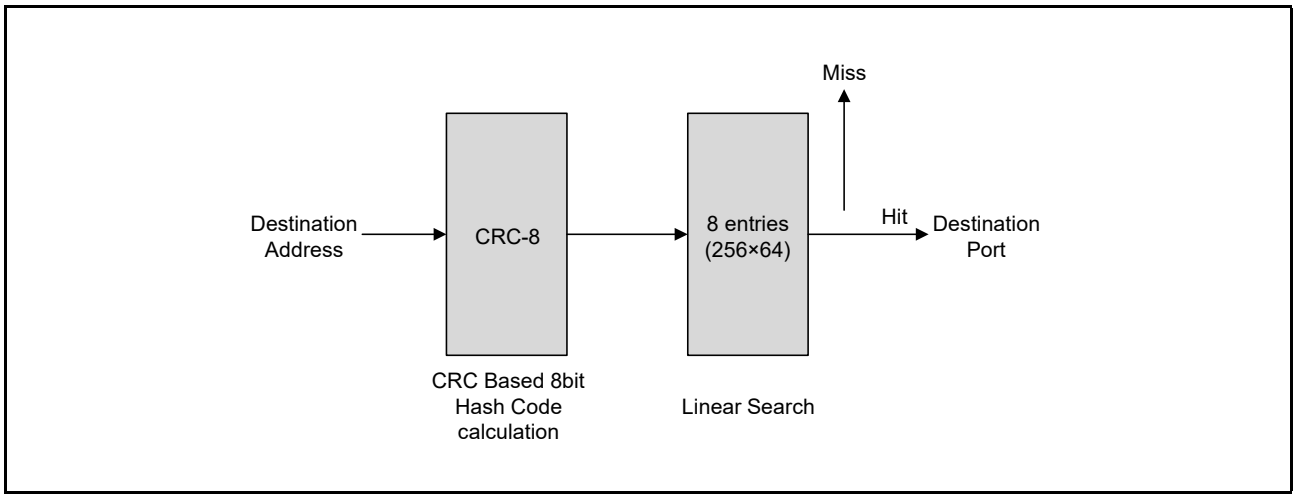

Figure 29.7 Port Look-Up Overview

(2) Hash Code

A MAC address table with up to 2048 entries is used in calculating 8-bit hash values from the least significant 24 bits (or all 48 bits) of the MAC addresses. The hash codes are calculated by using a CRC-8 polynomial: $x^8 + x^2 + x + 1$ (07h)
The 8-bit CRC is used also for all smaller address tables down to 256 entries. In this case, every hash value directly points to one entry in the memory and the 8-entry blocks overlap.
Note: The address table size of this LSI is 256 entries.

(3) Address Table

The address table is divided into blocks. Each block contains 8 records, which contain 64-bit of information each. Each record contains the 48-bit MAC address and provides the necessary forwarding information as well as priority or time stamp information. The start address of such an 8-entry block is defined by the hash value calculated from the MAC address. Two types of records are defined.

- Dynamic Record: The dynamic entry provides the MAC address together with a 10-bit timestamp and destination port number. These entries are created by the learning function based on received frames and this enables forwarding of frames to specific ports. Dynamic entries are deleted by aging function if not updated.
- Static Multiport/Priority Record: static entries can be written in the address table and include priority information as well as multiple destination port numbers (port bit mask). The MAC address can be unicast or multicast. These records can be used to e.g. specify the ports to participate in a specific multicast domain or to assign a MAC address-based priority to a frame. The aging and learning functions ignore static records.

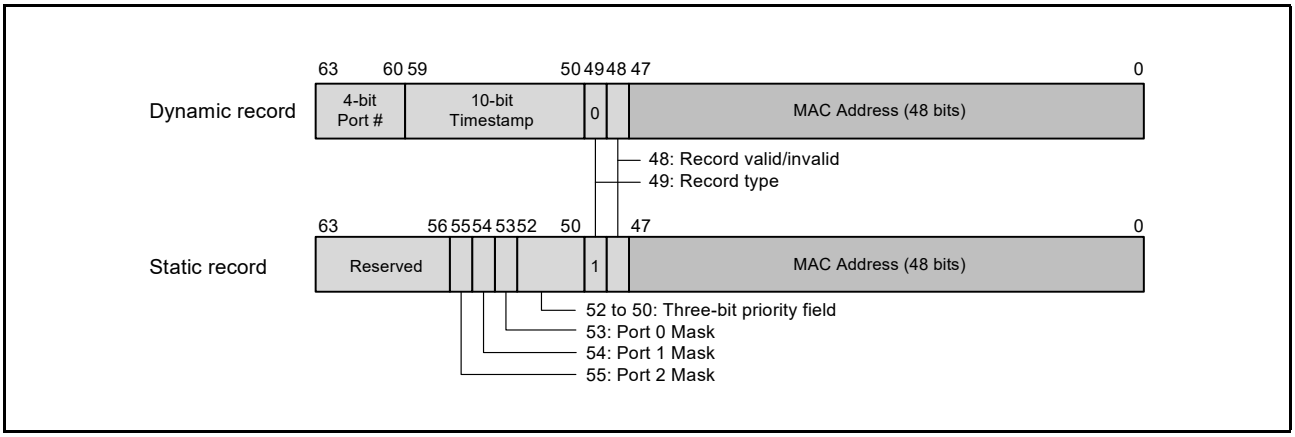

Figure 29.8 Record Types of Address Table

Bit 49 of the record indicates the type of records in the table.
The value 0 indicates that the entry is dynamic, so the higher-order bits of the record will consist of a 10-bit timestamp and 4-bit port number.
The value 1 indicates that the entry is static and has a 3-bit priority field and 3-bit port bit masks. Of the port bit masks, bits 53, 54, and 55 of the record correspond to ports 0, 1, and 2 (the internal port). The frame will be forwarded to each of the ports for which the value of the bit mask is 1. However, a frame is never forwarded to the source port even if the value of its port bit mask is 1.

29.3.1.5 Learning Interface

The learning interface provides to software the information required to build the look-up tables. The interface implements a FIFO buffer that stores multiple entries.

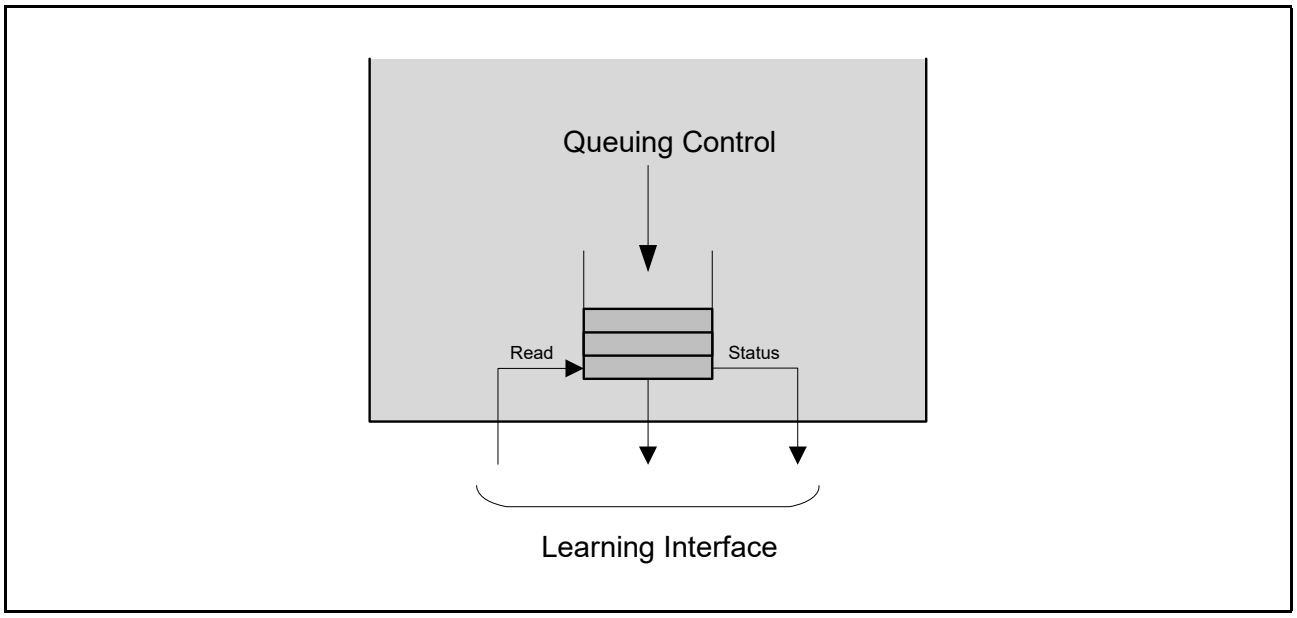

Figure 29.9 Learning Interface Overview

For each frame received by the switch, two 32-bit records (records A and B) are written in the FIFO, record A is written first, then record B.
Records A and B include the MAC address of frame transmit source, 8-bit hash code calculated based on the address, and port number of the transmission source. For the MAC address, the 1st octet is in bits 7:0 of the record A, and 6th octet is in bits 15:8 of the record B.

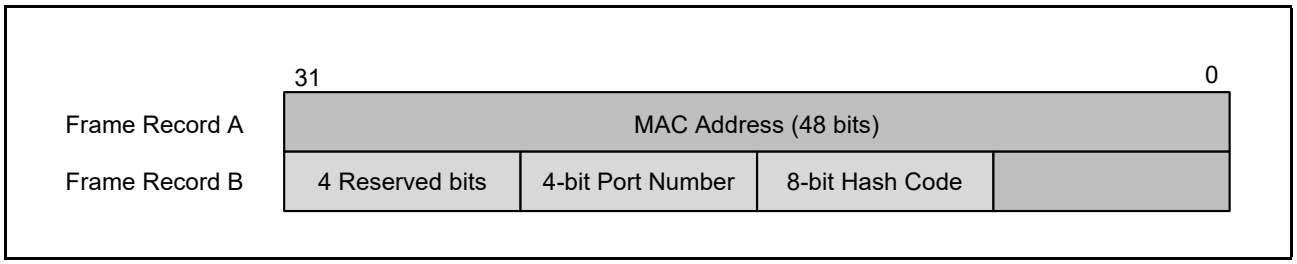

Figure 29.10 Format of Records

Software can read the records through registers LRN_REC_A and LRN_REC_B.

29.3.1.6 Frame Forwarding Tasks

(1) Overview

When a frame is processed, its 48-bit source and destination MAC addresses are extracted. The address table is searched for the destination MAC address. The following rules apply in the order from top to bottom:

(1) If the destination address is found, the frame is forwarded to the port(s) given by the address table entry.
(2) When (1) is not satisfied, but if the destination address is a unicast frame, the frame is forwarded to all ports identified by register UCAST_DEFAULT_MASK.
(3) When (1) is not satisfied, but if the destination address is a broadcast frame, the frame is forwarded to all ports identified by register BCAST_DEFAULT_MASK.
(4) When (1) is not satisfied, but if the destination address is a multicast frame, the frame is forwarded to all ports identified by register MCAST_DEFAULT_MASK.
(5) When (1) to (4) are not satisfied, the frame is forwarded to all ports identified by register BCAST_DEFAULT_MASK.

Note that the address table can hold static entries, and multicast addresses can be registered to static entries. Therefore, specific multicast addresses can be forwarded by using static entries without setting register MCAST_DEFAULT_MASK.

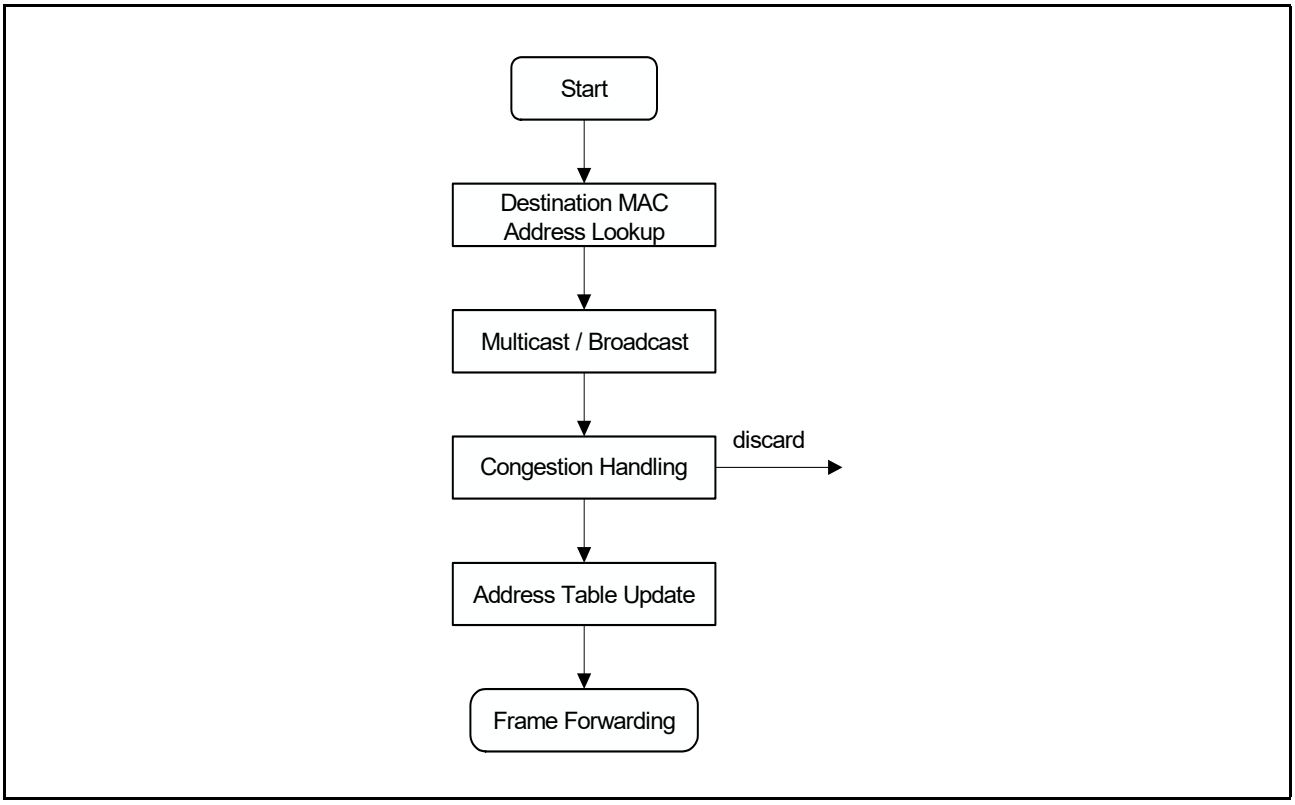

Figure 29.11 Frame Forwarding Tasks Overview

(2) Congestion Handling

(a) Overview

The congestion handling function is used whenever an output port is not available and data needs to be sent to the port. “Available” is defined as a state if the port is enabled through the PORT_ENA register and the corresponding output queue has enough room to store a full sized frame. In congestion handling, the frame should be processed further or discarded according to the following rules:

(b) Single Destination (one input to one output)

If the output port is enabled and can accept a frame, the frame will be forwarded normally. In any other case, the frame will be discarded.

(c) Multiple Destinations (Flooding)

After broadcast, multicast, or flooding handling, a frame needs to be forwarded to multiple output ports.

- Output disabled:
  All disabled ports are removed from the list of outputs.
- Output congested:
  If any of the output ports cannot accept a frame (as indicated by the output queue management for the port) due to output congestion, the port is removed from the list of outputs.

After the removal of the output list, if no available output port is left in the list, if the frame is read from the input and discarded. The port's corresponding discard counter (ODISCn) is incremented.

(3) Bridge Protocol Frame Handling

To implement bridge control protocols like the spanning tree protocol, the following control functions are performed by protocol frame handling function:

(a) Input Port Blocking

Input port blocking function is used to avoid forwarding of frames after address learning. Enabling or disabling of the function can be set through the INPUT_LEARN_BLOCK register. If a frame is received on a port which should block and the frame is not a bridge protocol frame, the frame will be targeted for discard and will not be forwarded to any output port.

(b) Input Port Learning Disabling

To reduce processing load of software, a port can be configured for exclusion from learning (see the INPUT_LEARN_BLOCK register). When learning is disabled on a port, no source address is extracted for incoming frames. BPDU frames, as exception, the source addresses are always extracted and forwarded to the learning interface.

(c) Management Port (Internal Port) Forwarding

When bit 6 of the MGMT_CONFIG register is enabled, the bridge protocol frames are always forwarded to the management port (internal port), independent of any address lookup or other handling functions.
The bridge protocol frames are identified by its destination address of the following:

- 01-80-c2-00-00-00 to 01-80-c2-00-00-0F (Spanning Tree, IEEE 802.1d)
- 01-80-c2-00-00-10 (Bridge Management Address, 802.1d)
- 01-80-c2-00-00-20 to 01-80-c2-00-00-2F (Generic Attribute Registration Protocol, 802.1d)

(d) Management Frame Forwarding

If the management port (internal port) transmits frames, they are forwarded according to the port mask settings of bits 17 and 16 configured in register MGMT_CONFIG. A handshaking mechanism is implemented (bit 5 in register MGMT_CONFIG) that can be used to change the port mask configuration on a frame-by-frame basis for management frames.

(4) Forced Forwarding

The switch has the capability to disable the forwarding method specified by the forwarding processing and to forward a frame to a specific port forcibly. This is typically used for management frames that use multicast addresses but still need to be forwarded only to specific output ports.
Depending on the switch application, two methods exist:

- When a BPDU is forwarded, the mask defined in the MGMT_CONFIG register can be used. The application needs to set the register prior to transferring the BPDU frame to the switch. Afterwards, bit 5 that notifies completion of the transfer is set, the port mask can be cleared.
- Forced forwarding can be set per frame by using the management tag which can be used between the internal port and the Ethernet switch. This is the preferred method as it does not need any handshaking with the MGMT_CONFIG register.

A difference between two methods above is target frames for forced forwarding: the former is only for BPDU frames and the latter is for all frames.

Note: For forced forwarding by the management tag, bits 17 and 16 in MGMT_CONFIG must always be set to 0. Otherwise, the setting of the management tag will be overwritten due to precedence of the setting of MGMT_CONFIG.

29.3.1.7 Output Frame Queuing

(1) Overview

The memory controller implements a shared memory architecture to store frames of arbitrary size for multiple output ports.
Each output port can have multiple (up to 4) priority queues. The memory controller offers a single write input port (write port) and multiple output ports with the capability to perform virtual frame duplication on the output ports (multiple read ports).
A single large memory is partitioned in small cells to efficiently share the available memory for small and large frames without leaving large unused space when storing small frames.

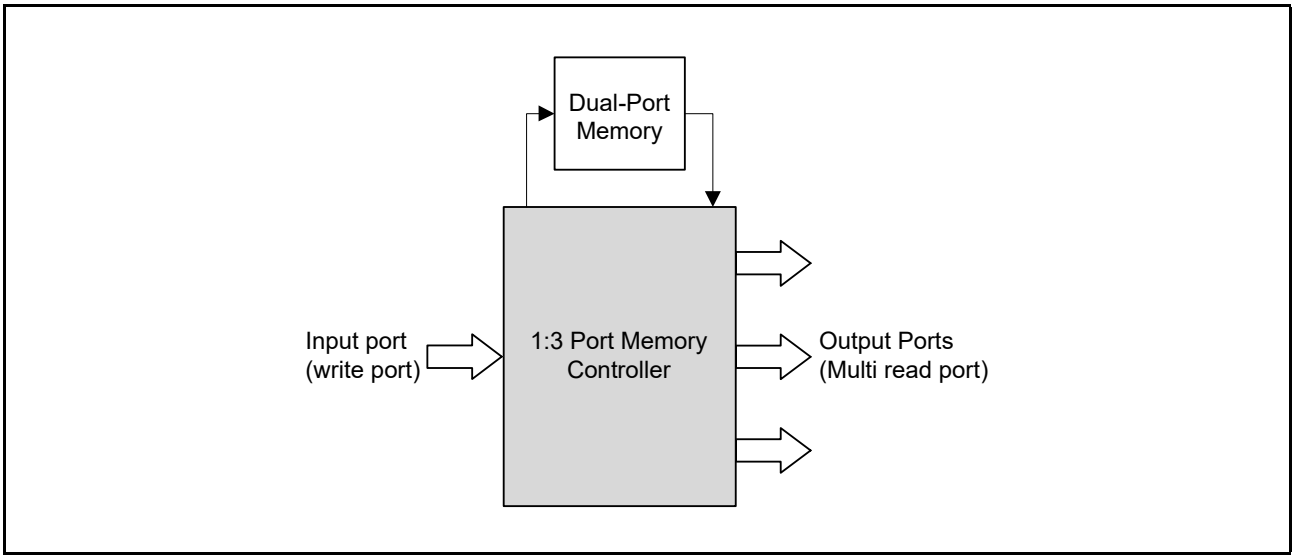

Figure 29.12 Overview of Output Port Memory Controller

(2) Functions

- Memory controller with single write port and multiple read ports
- Shared memory (8 Kbytes) partitioned in 256-byte cells
- Simultaneous write to multiple destinations during writing to memory from input port (virtual frame duplication)
- Multiple read ports using time-division multiplexing for simultaneous output serving to multiple output ports
- Multiple queues (4 stages) per output port
- Function to use congestion information for protection of backpressure and overflow
- Memory status statistics

(3) Implementation

The memory manager implements a shared 8-Kbyte storage for all queues on output ports 0 and 1 only. Port 2 (internal port) has a single FIFO queue, which operates independently of the shared memory. Therefore, even if the local port is congested due to slow processing by software, the forwarding between ports 0 and 1 is not affected.

29.3.2 Hub Module for Cut-Through

The Ethernet switch incorporates hub module for cut-through. This module enables high-speed frame transfer without using the switch engine between port 0 and port 1.
The hub module operates between the MAC and PHY at the MII level. The hub can operate on packets coming from both port 0 and port 1, or only one port. When the hub is enabled for only one port, in one direction cut-through can occur while store and forward is implemented in the other direction. The direction and enabling/disabling of the hub module can be controlled by software.
When the hub module is enabled, all frames received are immediately forwarded to the opposite port before the frame has been received (cut-through transfer). The filters in the module can be configured to avoid cut-through forwarding for specific management frames that must always be routed through the switch with the normal store and forward behavior.

29.3.2.1 Operation of Normal Switch Mode

In normal switching mode, the MAC is directly connected to the Ethernet PHY and data are transmitted and received in the switch. The switch engine is responsible for forwarding all frames between the individual ports.

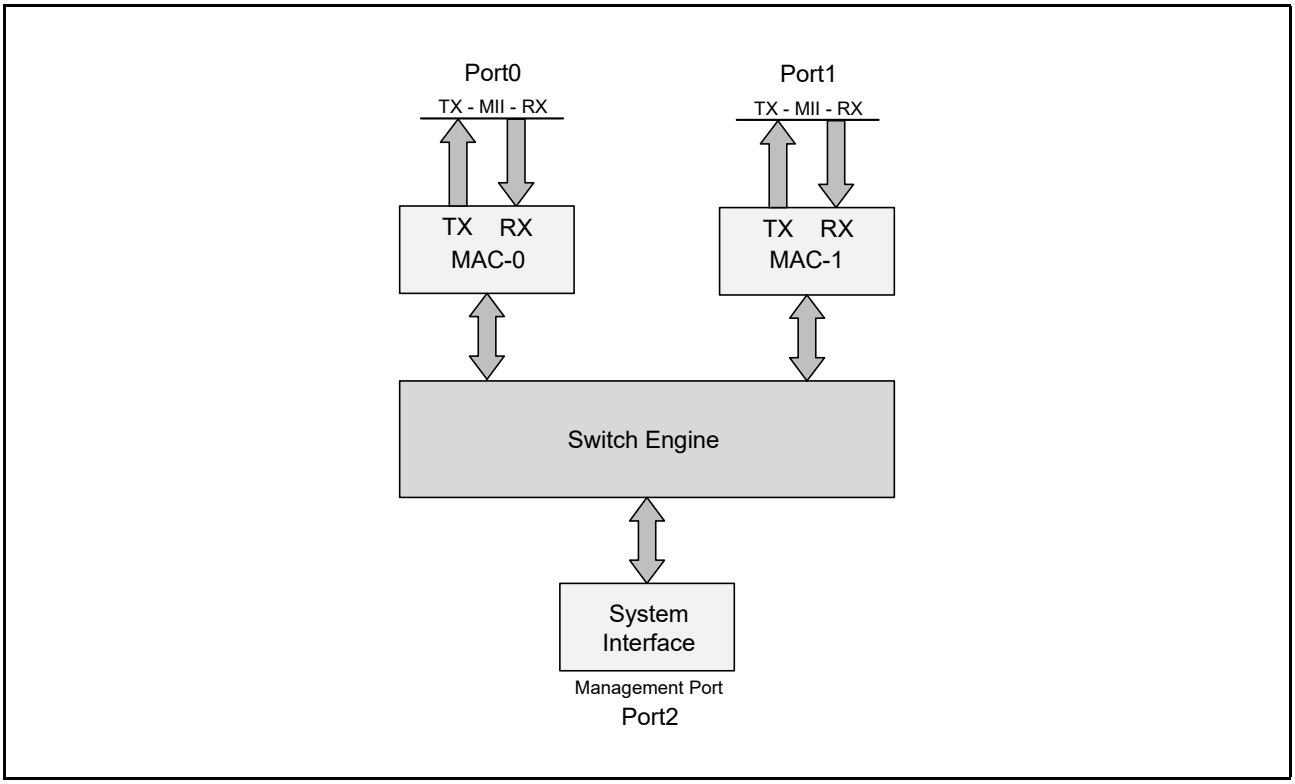

Figure 29.13 Normal Operation of Switch Mode

29.3.2.2 Hub Mode from Port 0 to Port 1

When hub mode is active in the direction from port 0 to port 1, the datapathes are changed at the PHY interface level as follows:

- The port 0 receive interface is connected to both the switch and the hub receive sides. The hub will transmit received frames to the port 1 transmit interface. A filtering mechanism is implemented to avoid frame duplication.
- The switch can transmit frames to port 0 normally and will continue to receive all traffic from port 0.
- The switch will receive frames from port 1 normally.
- For transmission to port 1 by the switch, it is necessary to avoid frame duplication as it must be ensured that it does not repeat frames that were already forwarded or are queued for transmission through the hub. The address filter table is used for this purpose.
- IEEE 1588 frames must never pass through the hub to ensure proper operation of the protocol (correction field updates).

When the hub mode is active in the direction from port 0 to port 1, the datapathes are changed at the PHY interface level as follows:
Even when hub mode is enabled, the frame received is transmitted to the switch and its transfer method of the frame will be determined in the switch. However, in case forwarding takes place to the same port as the port to which the hub already transmitted, the frame is discarded. Data transfer to the internal port (port 2) can occur. A FIFO is used for arbitration of frames transmitted from both the switch and the hub.

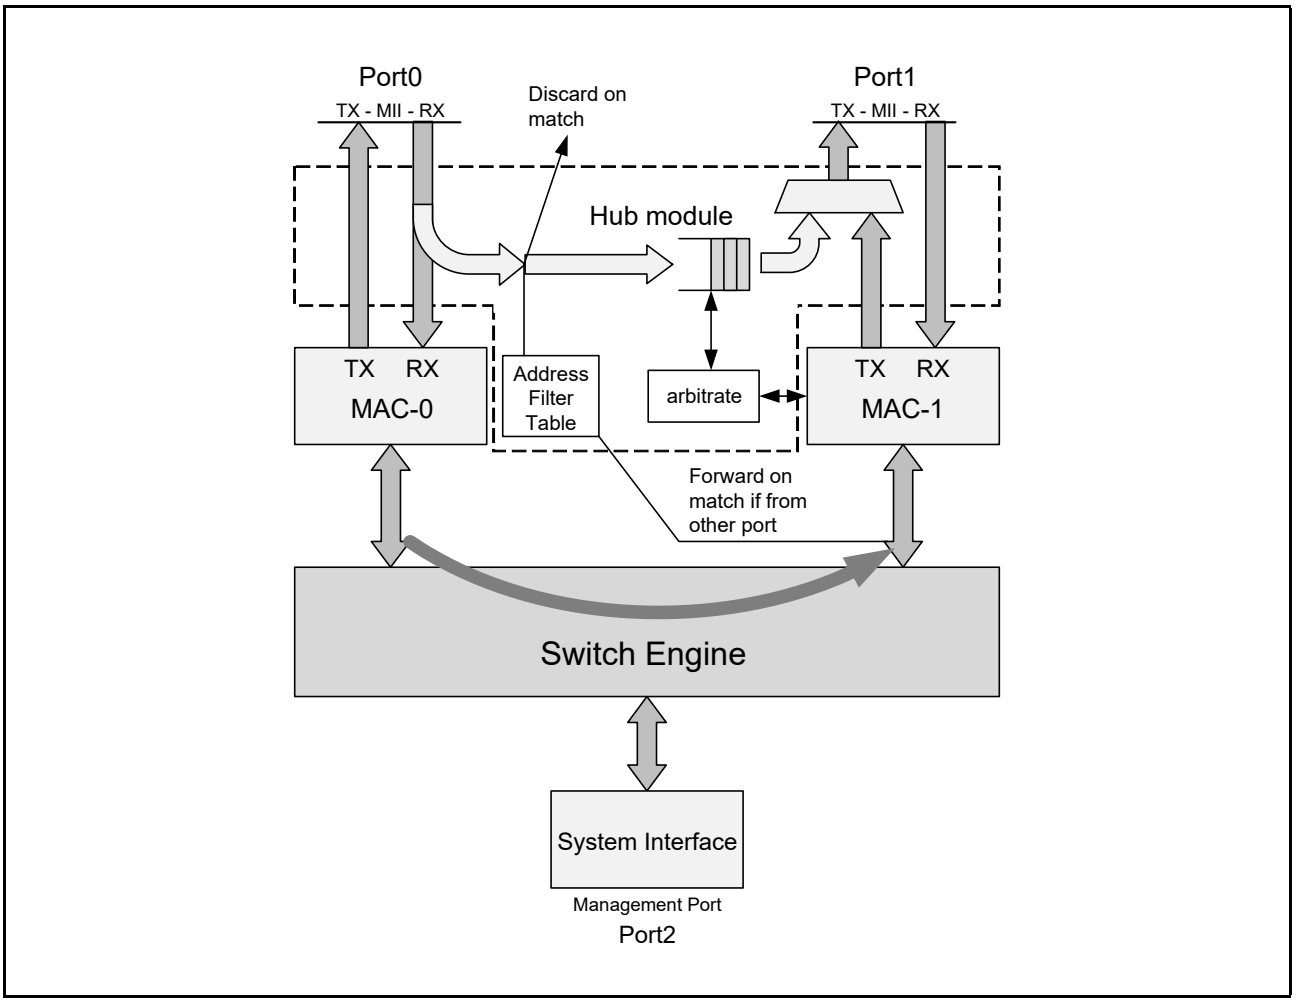

Figure 29.14 Hub Mode from Port 0 to Port 1

29.3.2.3 Hub Mode from Port 1 to Port 0

When the hub mode is enabled in the direction from port 1 to port 0, the datapathes are changed at the PHY interface level to receive from port 1 and transmit to port 0 directly. Now the transmission from both the switch and the hub to port 0 is arbitrated. The operation is the same as that of the hub mode in the direction from port 0 to port 1.
Note that both directions can be enabled separately and also both can be enabled at the same time.

29.3.2.4 Hub Receive Filtering

When the hub mode is enabled, the hub receive interface must not forward the following frames through the hub:

- Frames having a unicast MAC destination address matching the local system's unicast MAC address
- IEEE 1588 frames
- Any local management frames (e.g. MAC pause frames) that should not be transmitted through a switch

The hub receive filter operates on MAC destination addresses. Up to 7 addresses can be registered for filtering with the ability to use a mask on the last byte to cover address ranges and to perform forced forwarding instead of filtering (see sections of the HUB_FLT_MACnlo and HUB_FLT_MACnhi registers).
Forwarding operation of the hub and switch differs due to the setting of the filter.

Table 29.2 Operations of the Hub and Switch by Filter Settings

Forced Forwarding		**Disabled**		**Enabled*1**	
Address Match/Mismatch		**Match**	**Mismatch**	**Match**	**Mismatch**
Hub function enabled	Hub	Not forward	Cut-through	Cut-through	Filter behavior of invalid forced forwarding
	Switch	Store and forward*2	Not forward	—*3	
Hub function disabled	Hub	Not forward	Not forward	Cut-through	
	Switch	Store and forward*2	Store and forward*2	—*3	

Note 1. Use of the DLR for beacon frames is assumed.
Note 2. Forwarding frames between the PHY ports. May not be forwarded, depending on the settings of the address table and the default mask.
Note 3. Frames will be discarded before they enter the switch.

- When frame forced forwarding is disabled

When the destination address of a received frame matches with the one registered in the filter, the hub does not forward the frame to other port. When transfer between port 0 and port 1 in the switch occurs, the hub forwards the frame to the other port.
When the destination address of a received frame does not match with the one registered in the filter, the hub forwards the frame to the other port. On the other hand, the switch does not forward the frame to other port. This prevents any frame duplication.

- When frame forced forwarding is enabled

When the destination address of a received frame matches with the one registered in the filter and even when the hub mode is disabled, the hub always forwards the frame to other port. Generally, forced forwarding is applied to the beacon frames. When DLR mode is enabled, the DLR module can process the beacon frame, but the frame is discarded before acquiring by the switch. This prevents any frame duplication.

The management port (port 2) is not affected by any frame filtering and will always receive frames from both MAC ports.
The system must set up the filter address to contain the local system unicast MAC address as well as any destination (multicast) addresses of the IEEE 1588 frames and of the frames that should not be forwarded through the hub with forced forwarding bit disabled. The following tables give typical examples of relevant addresses. For the details, see relevant specifications.

Table 29.3 PTPv2 Multicast Domains for Layer 2

Name	MAC Address Mapping
Normal messages	01-1b-19-00-00-00
Peer delay messages	01-80-c2-00-00-0e

Table 29.4 PTP Multicast Domains for UDP/IP

Name	IP Address	MAC Address Mapping
Default PTP domain	224.0.1.129	01-00-5e-00-01-81
Alternate PTP domain1	224.0.1.130	01-00-5e-00-01-82
Alternate PTP domain2	224.0.1.131	01-00-5e-00-01-83
Alternate PTP domain3	224.0.1.132	01-00-5e-00-01-84

Table 29.5 Management Frame Domains

Name	IP Address	MAC Address Mapping Mapping
Generic Switch Management	224.0.0.0	01-00-5e-00-00-00
IGMP	224.0.0.1	01-00-5e-00-00-01

Table 29.6 Switch Management Frame Domains

Name	MAC Address Mapping
Spanning Tree, IEEE 802.1d	01-80-c2-00-00-00 to 01-80-c2-00-00-0F
Bridge Management Address, 802.1d	01-80-c2-00-00-10
GARP	01-80-c2-00-00-20 to 01-80-c2-00-00-2F
MAC Layer Control Frames (Pause)	01-80-c2-00-00-01

Table 29.7 DLR Multicast Domains

Name	MAC Address Mapping
Beacon Frame	01-21-6C-00-00-01
Neighbor Check Request, Neighbor Check Response, Sign ON	01-21-6C-00-00-02
Announce, Locate Fault	01-21-6C-00-00-03

Based on the above, filter initialization for the hub module should cover at least the addresses listed in Table 29.8.
The address and mask values are programmed using the HUB_FLT_MACnlo and HUB_FLT_MACnhi registers. Note that the first byte of the MAC address must be set in bits 7 to 0 of the HUB_FLT_MACnlo register. The logical AND of values of the mask and the last byte of the address of the received frame is taken and the result is compared with the specified address.
The forced forwarding bit should be set to 1 only when the frame should always be forwarded through the hub. Note that forced forwarding operates regardless of the hub setting (enabling or disabling). That is, when the hub module is disabled, the forced forwarding can still be used for cut-through forwarding of only specific frames.
Broadcast frames should not be forwarded through the hub without any clear request by application. Broadcast addresses are needed to be input to the filter table. Filtering can be enabled through the control bit in the HUB_CONTROL.

Table 29.8 Typical HUB MAC Filter Setup

MAC Address	Mask	Forced Forwarding	Notes
01-80-c2-00-00-00	C0h	0	Filters all frames in range 01-80-c2-00-00-{00..3F} The register settings for MAClo and MAChi would be: HUB_FLT_MACnlo = 00C2 8001h HUB_FLT_MACnhi = 00C0 0000h
01-1b-19-00-00-00	FFh	0	Filters only this address (PTPv2)
01-00-5e-00-01-80	F8h	0	Filters 01-00-5e-00-01-{80..87}(224.0.1.{128..135})
01-00-5e-00-00-00	FCh	0	Filters 01-00-5e-00-00-{00..03} (224.0.0.{0..3})
<Local node unicast address>	FFh	0	Must be entered to avoid unnecessary forwarding of frames that are directed to the local node only.
01-21-6C-00-00-01	FFh	1	Must be forced-forwarded through the hub. The register settings for MAC6lo/ MAC6hi would be: HUB_FLT_MAC6lo = 006C 2101h HUB_FLT_MAC6hi = 01FF 0100h

29.3.2.5 Hub Module Forced Forwarding

Forced forwarding bit (bit 24 in HUB_FLT_MACnhi) can be set for each filter entry. The bit changes the filter function not to frame filtering, but to frame forced forwarding. When an address match occurs and forced forwarding bit is set for the address entry, a frame is forwarded through the hub (cut-through). On the other hand, a frame to be forwarded to the MAC or switch will be discarded before the MAC or switch receives. The forced forwarding takes place always, independent of the hub's enable control (bit 0 of HUB_CONTROL).
Due to the discard behavior in this mode of operation, a forced-forwarded frame is not processed by the switch. Hence no address learning can take place on such frames. It also cannot be forwarded to the local application through port 2. This is different from the normal hub operation, where all frames are still passed up to the switch normally and then discarded by the switch only at the line port to avoid duplication to the line.
As described in the next section, the DLR module will receive forced forwarded frames normally. This is because the module is located before the MAC or switch and is not affected by the discard. Thus, generally, the forced forwarding is expected to be used for DLR beacon frames. DLR module processing of the beacon frames enables to reduce load for application.

29.3.2.6 Loop Filtering

The hub module includes a loop filter that is capable of discarding frames with defined source addresses arriving at the receiving ports to prevent frames from the given addresses passing through the hub or switch. This is typically required within applications that are connected to the ring.
Frames transmitted from the local node may be received again after they passed through the ring, so once the loop filter has discarded a frame, it is completely removed from the network and never processed again by the hub or switch.
The MAC address local node for processing by the loop filter can be set in the LOC_MAClo and LOC_MAChi registers of the DLR module.

29.3.3 DLR Module

The Device Level Ring (DLR) module offers beacon frame processing on receive path of both port 0 and port 1 of the switch core.
The DLR module is inserted between the hub module and switch module. Beacon frames on receive paths are detected and discarded by the DLR module before entering the switch from both external ports. All the beacon frame parameters are interpreted and stored locally for software access.
Any ring status change for beacon based node implementation is notified to the CPU through the interrupt. This enables to read the received beacon frame parameters at any time. Statistics counters are implemented for the count of beacon frames received and transmitted.

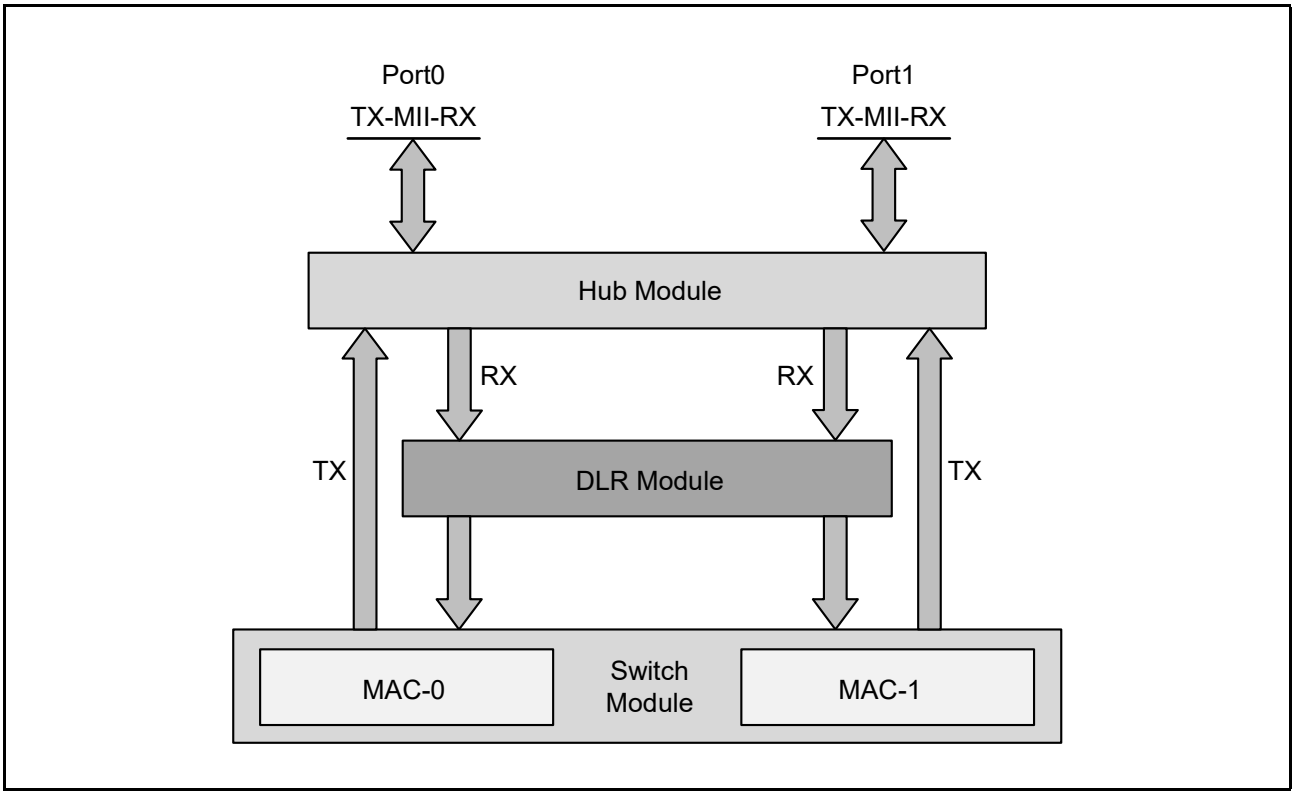

Figure 29.15 Connection Image of Hub Module and DLR Module

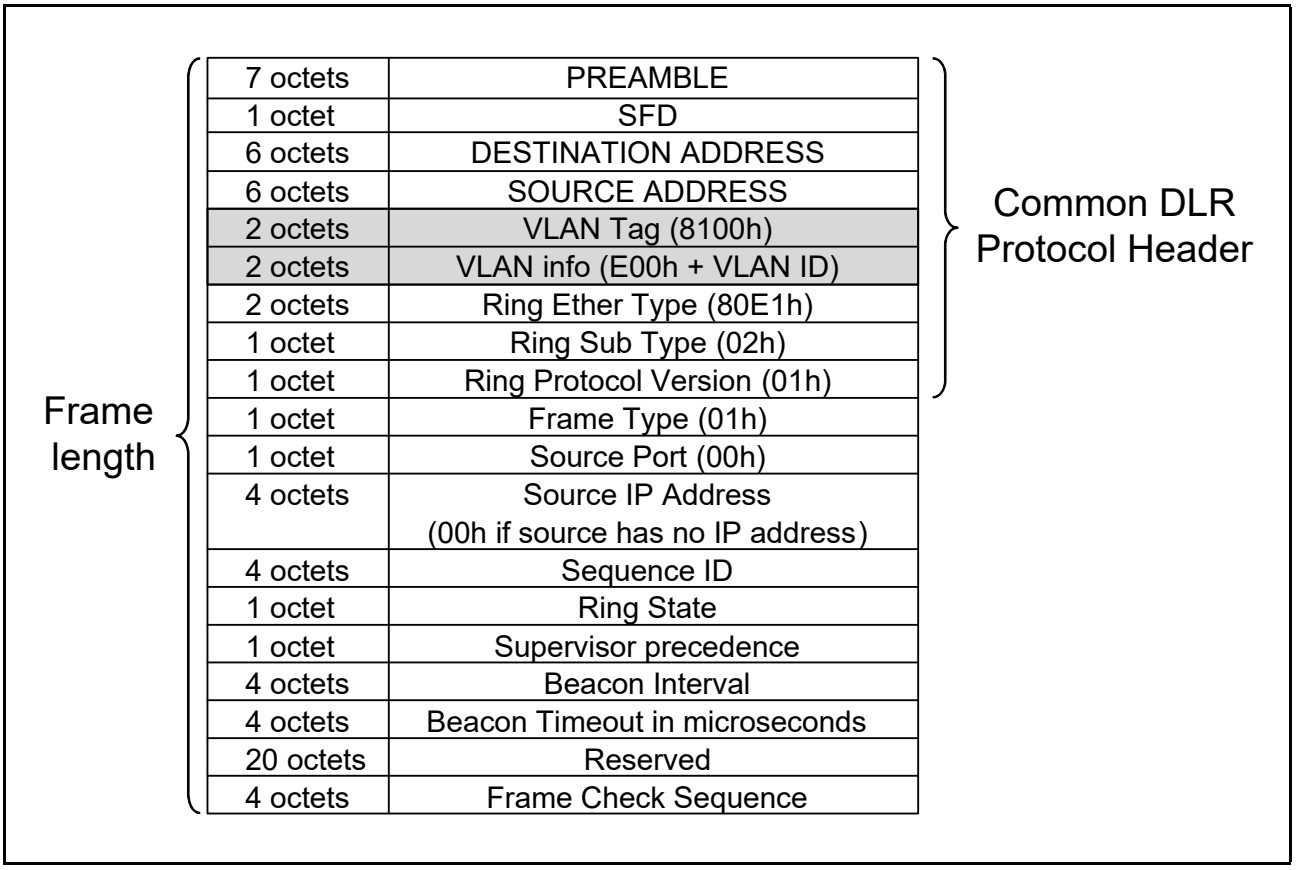
29.3.3.1 Beacon Frame Format

Within a DLR Network, the active ring supervisor transmits a beacon frame through both of its Ethernet ports in the beacon interval (400 microseconds by default). DLR frames use the frame format of 802.1Q. Frames are transmitted with highest priority (7). A beacon frame is the DLR frame with length of 64 bytes, excluding the preamble and the SFD. A beacon frame consists of the following fields:



7 octets	PREAMBLE
1 octet	SFD
6 octets	DESTINATION ADDRESS
6 octets	SOURCE ADDRESS
2 octets	VLAN Tag (8100h)
2 octets	VLAN info (E00h + VLAN ID)
2 octets	Ring Ether Type (80E1h)
1 octet	Ring Sub Type (02h)
1 octet	Ring Protocol Version (01h)
1 octet	Frame Type (01h)
1 octet	Source Port (00h)
4 octets	Source IP Address (00h if source has no IP address)
4 octets	Sequence ID
1 octet	Ring State
1 octet	Supervisor precedence
4 octets	Beacon Interval
4 octets	Beacon Timeout in microseconds
20 octets	Reserved
4 octets	Frame Check Sequence

Figure 29.16 Beacon Frame Format

Beacon frames are processed and parameters are stored in the local registers for the software access. Table 29.9 lists the fields of beacon frames and the names of the relevant registers which hold the values for the ring node.

Table 29.9 Beacon Frame Field Definitions

Term	Description	Register Name
Destination Address	The destination MAC address for the beacon frame is a fixed multicast address of 01-21-6C-00-00-01. This is an exclusive MAC address used only for beacon frames. Cut-through forwarding can be used based on this address match.	—
Source Address	Source MAC address of the supervisor. 48-bit address is stored in two separate registers.	SUPR_MAClo/ SUPR_MAChi
VLAN TAG	DLR messages contain 2 octets VLAN tag (8100h) after the source MAC address according to 802.1Q.	—
VLAN information	16-bit information field contains the priority field and the VLAN_ID. VLAN ID is configured at the ring supervisor and received by the ring nodes. The default value for the VLAN ID is 0 when there is no VLAN ID available. The default VLAN ID does not need to be changed unless a commercial switch is being used within the ring.	Bits 31 to 16 of STATE_VLAN When bit 8 is set to 1, the value is valid.
Ring Ether Type	Ether type for DLR frames is 80E1h	—
Ring Sub Type	Ring Sub type value is always 02h for the DLR messages	Bits 7 to 0 in ETH_STYP_VER
Ring Protocol Version	Protocol version for the DLR messages	Bits 15 to 8 of ETH_STYP_VER
Frame Type	Frame Type value for the beacon frame is always 01h	—
Source Port	Source port value is always 0h for the beacon frame	Bits 23 to 16 of ETH_STYP_VER
Source IP address	IP address of the supervisor. The default value for the IP address is 0 when there is no IP address available.	SUPR_IPADR
Sequence ID	Sequence identification number of the frame	SEQ_ID
Ring State	State of the ring network transmitted by the ring supervisor.	Bits 7 to 0 of STATE_VLAN
Supervisor priority	The ring supervisor priority value contains the priority value assigned to the ring supervisor. When multiple supervisors are enabled, the priority value enables the user to select a single supervisor with the highest priority. The ring supervisor’s priority value can be any value within the range from 0 to 255, with numerically higher values indicating higher priority.	Bits 23 to 16 of SUPR_MAChi
Beacon Interval	Interval in microseconds at which the ring supervisor sends beacon frames. The valid value is in the range between to minimum 100 microseconds and maximum 100 milliseconds. The typical value is 400 microseconds.	BEC_INTRVL
Beacon Timeout	Amount of time in microseconds, nodes shall wait before timing out reception of beacon frames and taking appropriate action. The valid value is in the range between minimum 200 microseconds and maximum 500 milliseconds. The typical value is 1960 microseconds.	BEC_TMOUT
Frame Check Sequence	CRC value for the frame	—

29.3.3.2 Functional Description of Ring Node

Beacon frames are detected and interpreted by the ring module, so that the CPU is not burdened with processing the beacon frames for ring node implementation. Any ring status change for beacon-based node structure is notified to the CPU through the interrupt.
It is also possible to read the received beacon frame parameters at any time. Statistics counters are also implemented to view the number of beacon frames received and transmitted.

(1) Initial Settings

The following are the steps to configure the DLR module:

- Set the 4 low-order bytes of the beacon destination address (006C 2101h) for register HUB_FLT_MAC6lo which is also the value after reset.
- Set the 2 high-order bytes of the beacon destination address and enable forced forwarding (01FF 0100h) for register HUB_FLT_MAC6hi which is also the value after reset. The mask bit is FFh.
- Set the 4 low-order bytes of the MAC address of the local device to the DLR module register LOC_MAClo which is used by the loop filter.
- Set the 2 high-order bytes of the MAC address of the local device to the DLR module register LOC_MAChi which is used by the loop filter.
- Set the DLR Ethernet frame type value of 80E1h to register DLR_ETH_ TYP which is also the value after reset.
- Enable the DLR module through the control register DLR_CONTROL. Number of cycles required to count 1 microsecond should also be set by this register. The DLR module of this LSI is 75 MHz, hence resister DLR_CONTROL needs to be set to 4Bh, which needs to be changed from the value after reset.
- Any interrupt source can be enabled or disabled through register DLR_IRQ_CTRL as required by the software.

(2) Start Up

Upon start up, the ring node will be in IDLE_STATE and presumes the network is in linear topology mode. The current state of the local ring node and other status bits are stored within the status register for software access.
An invalid timer value should be ignored by setting bit 4 of the DLR_CONTROL register. The beacon frame with invalid timeout timer value is received, the frame is ignored. On the other hand, an invalid timer value is stored in the INV_TMOUT register irrespective of the setting of bit 4 of DLR_CONTROL. An interrupt will also be generated by enabling through bit 11 of DLR_IRQ_CTRL.
Upon receiving a beacon frame through either port, the ring node shall transition to FAULT_STATE, which presumes the network is in ring topology mode. An interrupt will be generated by enabling bit 1 of DLR_IRQ_CTRL and this interrupt generation notifies the CPU of a need for flushing the MAC address learning table as well as a change in the state. All ring supervisor parameters will be saved within the register for software access. The following parameters will be saved only during transition from IDLE_STATE to FAULT_STATE:

- Supervisor's MAC address and will be stored in registers SUPR_MAClo and SUPR_MAChi.
- Supervisor's priority value will be stored in register SUPR_MAChi.
- VLAN ID will be stored in register STATE_VLAN.
- Beacon timeout timer value will be stored in register BEC_TMOUT.

The supervisor IP address is accepted to change at any time. A new IP address will always replace the old one and interrupt will be generated indicating a change in the IP address if enabled through bit 10 of register DLR_IRQ_CTRL.
If a beacon frame received from a different supervisor with a higher priority value or higher numeric value for MAC address even with the same priority level, new beacon frame parameters will replace all the old values. An interrupt will be generated indicating change of supervisor if enabled through bit 6 of register DLR_IRQ_CTRL. The ring node will stay in FAULT_STATE.
If a beacon frame received from a different supervisor with a lower priority value or lower numeric value for MAC address with same priority value, the beacon frame will be ignored. An interrupt will be generated indicating an ignored beacon frame if enabled through bit 9 of register DLR_IRQ_CTRL. The ring node will stay in FAULT_STATE.
The ring supervisor is not expected to change parameters within the beacon frame. If parameters need to be changed, the supervisor stops transmitting the beacon frame for at least two beacon timeout periods before transmitting beacon frames with new parameters.
If the local node state changes back to IDLE_STATE due to the elapse of the beacon timeout timer on both ports, it will generate an interrupt if enabled through bits 4 and 5 of register DLR_IRQ_CTRL. Current interrupt status is available for software access showing beacon timeout has occurred on both ports, need to erase the MAC address learning table and to change the state of register DLR_IRQ_STAT_ACK.
Upon receiving beacon frames through both ports and after receiving a beacon frame from the active ring supervisor with ring state field set to RING_STATE_NORMAL on either one of its ports, the local node shall transition to NORMAL_STATE. Interrupt status bits will show the change in the state, need to erase the unicast MAC address learning table and to stop neighbor check timeout timer when enabled within the software.

Note: Neighbor check time out timer (100 milliseconds) for neighbor check process should be implemented by the software. Software can use bits 3 and 2 of register DLR_IRQ_STAT_ACK to stop the timer.

(3) Fault Detection

Any of the following events shall cause the ring node to transition from NORMAL_STATE to other states:

- Receipt of a beacon frame with a state parameter set to RING_FAULT_STATE:
  Bit 0 of register DLR_IRQ_STAT_ACK is set indicating a change in the node state.
  An interrupt is generated when interrupt generation is enabled.
- Receipt of a beacon frame with a different MAC address or higher priority than the current active ring supervisor:
  In addition to state change, bit 6 of register DLR_IRQ_STAT_ACK is set indicating a change in the supervisor.
- A case that both ports failed to receive a beacon frame for a period specified by the beacon timeout value:
  The node state transitions to IDLE_STATE. In addition to the state change, bits 5 and 4 of register DLR_IRQ_STAT_ACK are set indicating timeout of the beacon timeout timer on the both ports.
- A case that one of the ports failed to receive beacon frame for a period specified by the beacon timeout period:
  The node state transitions to FAULT_STATE. In addition to the state change, bit 5 or 4 of register DLR_IRQ_STAT_ACK is set indicating timeout of the beacon timeout timer on the port.

(4) Error Handling

The DLR node is able to handle several error conditions:

- CRC errors detected in beacon frames:
  When a CRC error is detected in a beacon frame, the beacon frame in not processed in the DLR node and discarded before entering the switch. The parameters of the beacon frame with an error are not stored in the register. On the other hand, even with a beacon frame with an error Beacon frames with CRC errors are forwarded through the hub module since the hub does not check for CRC. Beacon frames with CRC error are counted by the statistics counter RX_ERR_STAT0 and RX_ERR_STAT1.
- Beacon frame timeout timer value in the invalid range:
  The valid range for the beacon frame time out timer value is between 200 microseconds to 500 milliseconds. When a beacon frame from the supervisor has an invalid value of the beacon timeout and if bit 4 of register DLR_CONTROL is set, the frame will be ignored and discarded before entering the switch. Regardless of this setting, beacon frames with an invalid timeout timer value are always detected and the invalid timeout value is stored within register INV_TMOUT. An interrupt is also generated if bit 11 of register DLR_IRQ_CTRL is set.

This document describes the DLR module incorporated in this LSI. For details of the DLR, see the relevant ODVA specifications.

29.3.4 IEEE 1588 Timer and Control Module

29.3.4.1 Overview

The timer and control module (TSM) implements an adjustable timer for IEEE 1588 implementations allowing synchronizing the local time of the timer to a remote master clock (through some protocol specific application software such as PTP).
In addition, the module provides the time base for all frame timestamping performed at the MAC/PHY interfaces of all external ports. The timestamps enable use of time synchronization protocols (e.g. IEEE 1588 Precision-Time-Protocol, PTP) to synchronize distributed clocks in the network to a common master clock.

29.3.4.2 IEEE 1588 Message Formats

(1) Transport Encapsulation

The Precision-Time-Protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or, in addition to UDP/IP, with PTPv2, directly described in Ethernet frames (Layer 2). Typically multicast addresses are used to allow efficient distribution of the synchronization messages.

- UDP/IP

The 1588 messages (v1 and v2) can be transmitted using UDP/IP multicast messages. The following IP multicast groups in Table 29.10 are defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112.

Table 29.10 UDP/IP Multicast Domains

Name	IP Address	MAC Address Mapping
Default PTP domain	224.0.1.129	01-00-5e-00-01-81
Alternate PTP domain1	224.0.1.130	01-00-5e-00-01-82
Alternate PTP domain2	224.0.1.131	01-00-5e-00-01-83
Alternate PTP domain3	224.0.1.132	01-00-5e-00-01-84

Table 29.11 UDP Port Numbers

Message Type	UDP Port	Note
Event	319	Used for SYNC and DELAY_REQUEST messages.
General	320	Any messages other than the above (e.g. follow-up, delay-response)

- Native Ethernet (Layer 2)

In addition to the usage of UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses EtherType = 88F7h. The payload of the Ethernet frame directly contains the PTP datagram, starting with the PTPv2 header.
Besides, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are additionally defined in PTPv2.

Table 29.12 PTPv2 Multicast Domains

Name	MAC Address
Normal messages	01-1b-19-00-00-00
Peer delay messages	01-80-c2-00-00-0e

(2) PTP Header

All PTP frames contain a common header, which is used to determine the protocol version as well as the type of message, which defines the further content of the message. All multi-octet fields are transmitted in big-endian order. The version field's last 4 bits are at the same position for both PTPv1 and PTPv2 headers, allowing a correct identification by inspecting the first 2 bytes of the message.

Note: For details on the meaning of the PTP frame contents, see the IEEE 1588 specification. The following sections only describe some of the relevant information that may be useful to help the reader to understand some of the terms used in the documentation. PTPv1 refers to the version 1 of the IEEE 1588 standard specification. PTPv2 refers to version 2 of the standard.

- PTPv1 Header

Table 29.13 Common PTPv1 Message Header

Bits									
7	**6**	**5**	**4**	**3**	**2**	**1**	**0**	**Octets**	**Offset**
versionPTP = 0x0001								2	0
versionNetwork								2	2
subdomain								16	4
messageType								1	20
sourceCommunicationTechnology								1	21
sourceUuid								6	22
sourcePortId								2	28
sequenceId								2	30
control								1	32
0x00								1	33
flags								2	34
reserved								4	36

The type of message is encoded in the messageType and control fields as follows:

Table 29.14 PTPv1 Message Type Identification

messageType	Control	Message Name	Message
0x01	0	SYNC	Event message
0x01	1	DELAY_REQ	Event message
0x02	2	FOLLOW_UP	General message
0x02	3	DELAY_RESP	General message
0x02	4	MANAGEMENT	General message
Others	Others		Reserved

- PTPv2 Header

Table 29.15 Common PTPv2 Message Header

Bits								Octets	Offset
7	6	5	4	3	2	1	0		
ransportSpecific				messageId				1	0
reserved				versionPTP = 0x2				1	1
messageLength								2	2
domainNumber								1	4

flags								2	6
correctionField								8	8
reserved								4	16
sourcePortIdentity								10	20
sequenceId								2	30
control								1	32
logMeanMessageInterval								1	33

The type of message is encoded in the messageId field as shown in Table 29.16.

Table 29.16 PTPv2 Message Type Identification

messageId	Message Name	Message
0x0	SYNC	Event message
0x1	DELAY_REQ	Event message
0x2	PATH_DELAY_REQ	Event message
0x3	PATH_DELAY_RESP	Event message
0x4 to 0x7		Reserved
0x8	FOLLOW_UP	General message
0x9	DELAY_RESP	General message
0xa	PATH_DELAY_FOLLOW_UP	General message
0xb	ANNOUNCE	General message
0xc	SIGNALING	General message
0xd	MANAGEMENT	General message

The PTPv2 flags field contains further details on the type of message, especially if one-step or two-step implementations are used. The flags field consists of two octets with the following meanings for the bits. Reserved bits are set to 0.

Table 29.17 PTPv2 Message Flags Field Definitions

Octet Offset	Bit	Name	Description
6 (first)	0	ALTERNATE_MASTER	See IEEE 1588 Clause 17.4
	1	TWO_STEP	0: One-step clock 1: Two-step clock
	2	UNICAST	0: Multicast Address 1: Unicast Address
	3, 4	Reserved	
	5	Profile specific	
	6	Profile specific	
	7	Reserved	

Note: See the IEEE 1588 specification for details on frame formats and these fields.

29.3.4.3 Adjustable Timer Module

(1) Overview

The adjustable timer module (TSM) implements the Free Running Counter (FRC), the timer, which is used to generate the timestamps for received and transmitted frames. The FRC operates with the clock (100 MHz), whose time resolution is 10 ns.

Through a dedicated correction circuit, the timer can be adjusted allowing synchronization to a remote master and provide a synchronized timing reference to the local system. The timer consist of a nanosecond-timer and second-timer. When the nanosecond-timer reaches 10^9, an interrupt is generated.

It is possible to generate the synchronous pulse signal which is arbitrary period based on the current time of the FRC. Time reference can be provided to the external system of this LSI.

(2) Adjustable Timer Implementation

The adjustable timer consists of a programmable counter/accumulator and two correction counters. The periods of the counters and its increment rate are freely configurable allowing very fine tuning of the timer.

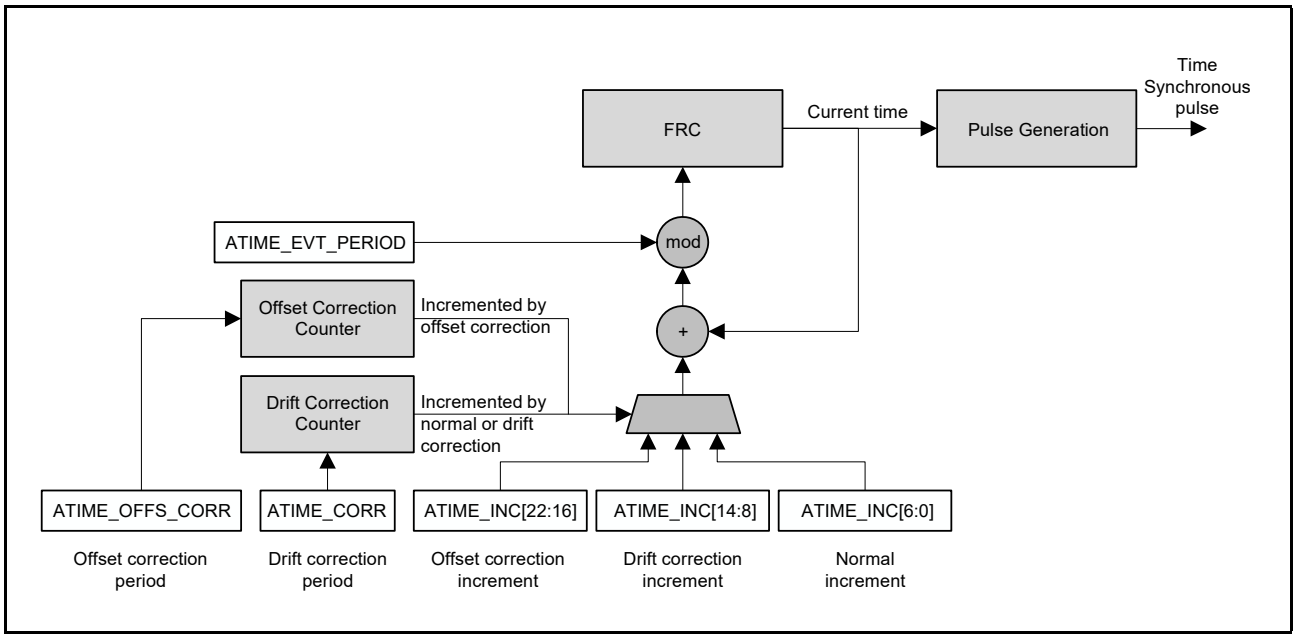

Figure 29.17 Adjustable Timer Structure

(3) Normal Timer Operation

The Free Running Counter (timer) continues to produce the current time. A constant value is added to the current time per clock cycle as programmed in bits 6 to 0 of the ATIME_INC register. To obtain accurate time, the ATIME_INC bits 6 to 0 always need to be set to 001010b, which represents in 10 ns.

The period, configured in register ATIME_EVT_PERIOD, defines the modulo and is used when the counter has to wrap around. The period must always be set to 10^9. By this setting, all timestamps can be used in nanoseconds.

(4) Drift Correction

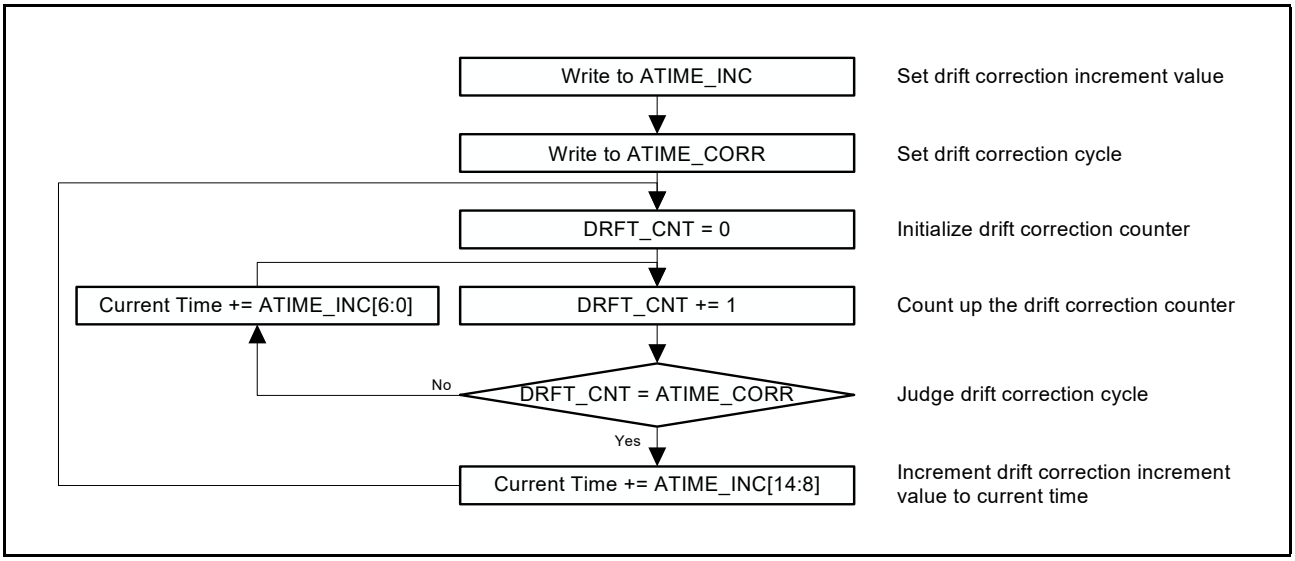

Figure 29.18 Drift Correction

The drift correction counter operates fully independently of the FRC (timer) and increments by 1 with each clock cycle. When it reaches the value configured in ATIME_CORR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value. The normal and correction increments are configured in register ATIME_INC. To speed up the timer, the correction increment would be larger than the normal increment value. To slow down the timer, the correction increment would be smaller than the normal increment value. Note that the correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections (low jitter) happening in the range of 1 ns independently from the clock frequency.

(5) Offset Correction

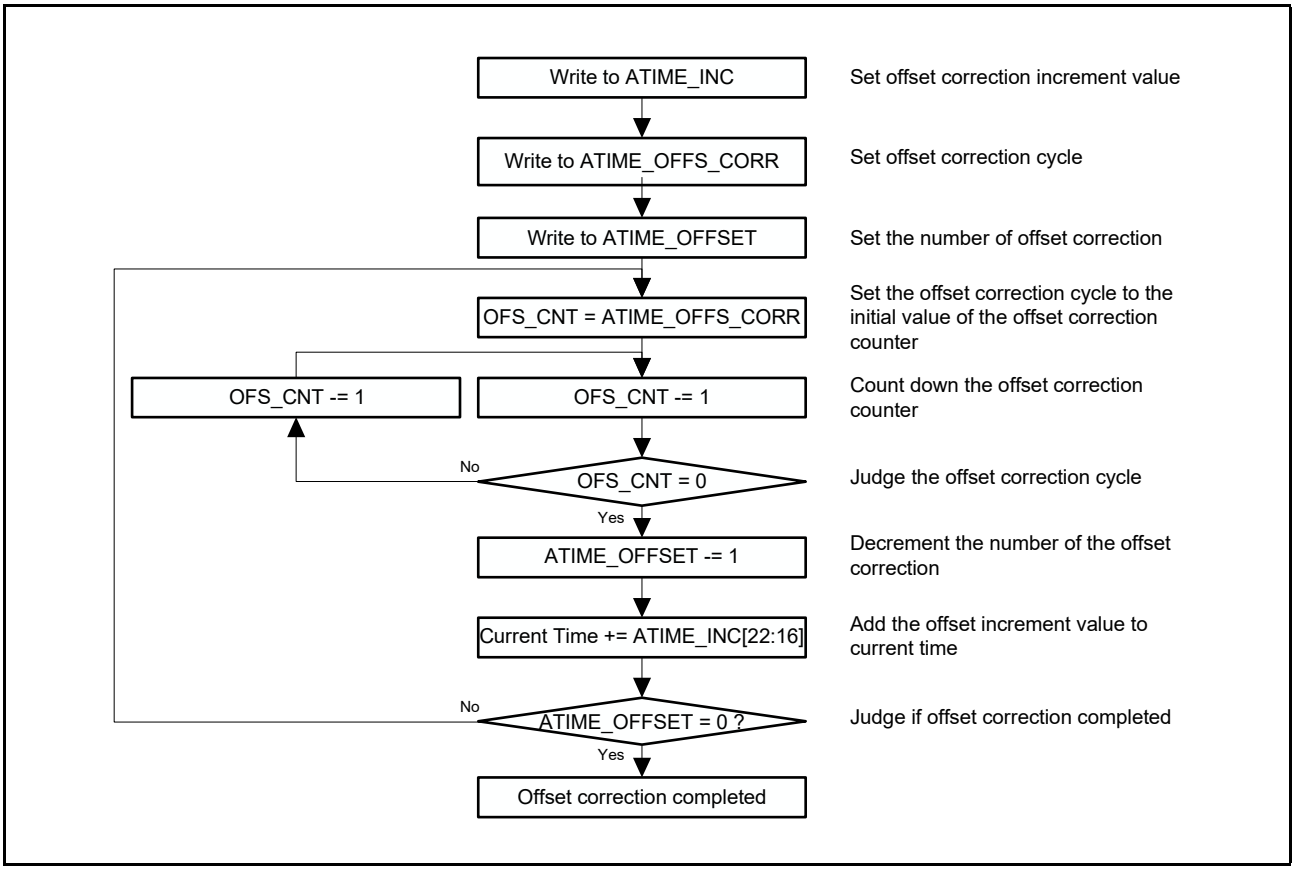

Figure 29.19 Offset Correction (When ATIME_OFFS_CORR is not 0)

The offset correction counter operates fully independently of the FRC (timer) and decrements by 1 with each clock cycle, when a value is loaded. It can be loaded with a value by writing register ATIME_OFFS_CORR. The timer does not start until an offset correction has been written into ATIME_OFFSET (i.e. the ATIME_OFFS_CORR must be written before writing the ATIME_OFFSET value).

When a value is written into ATIME_OFFSET, the offset correction counter is loaded with ATIME_OFFS_CORR and starts counting. When it reaches 0, it decrements the ATIME_OFFSET value and applies the offset correction increment as defined in bits [22:16] of ATIME_INC to the time counter. If the ATIME_OFFSET value is not 0 after it was decremented, the counter is reloaded with ATIME_OFFS_CORR value and the cycle repeats. This will repeat until the value in ATIME_OFFSET has reached 0, after which no more corrections will be performed.

With this correction, it is possible to shift the timer to another time without causing an immediate jump in time. When the offset correction has completed, the ATIME_OFFSET register will read out 0 and the offset event interrupt can be triggered as needed.

Instead of distributing the offset correction over time using the offset correction timer, it is possible to immediately change the current time by the offset amount. This leads to a jump of the timer to the time *current-time + offset*. Setting ATIME_OFFS_CORR to 0 and then writing the offset into ATIME_OFFSET achieves this. A positive or negative value can be written to adjust the timer accordingly.

(6) Pulse Signal Generation

This LSI chip is capable of generating desired periodic pulse signals (SYNCOUT signals) based on the current time values output by the timer.

Table 29.18 Parameter List of Pulse Signal Generation

Parameter	Registers	Description
Pulse generation enable	SWTMEN	Enables or disables to output pulse signal
Pulse output start time	SWTMSTSEC SWTMSTNS	Set the start time of the output signal in seconds and nanoseconds. After set the start time and set 1 to the SWTMEN register in order to enable to output the pulse signal, the pulse output starts when current time is over the start time set. If pulse output is enabled after the set start time, no pulse is output.
Pulse period	SWTMPSEC SWTMPNS	Set the pulse period of the output signal in seconds and nanoseconds. The value set in the SWTMPNS register must produce an integer when used as a divisor for the value for one second which is set in the ATIME_EVT_PERIOD register and be a multiple of 10 ns. The value must be set before pulse output is enabled.
Pulse width	SWTMWTH	Set the pulse high level width in nanoseconds. The value must be a multiple of 10 ns. If the pulse width set in the SWTMWTH register is greater than pulse period, output is fixed to high level. If the pulse width is set to 0, no pulse is generated and output is fixed to low level. The value must be set before pulse output is enabled.
Pulse rising time latch	SWTMLATSEC SWTMLATNS	The pulse output rising time is latched into the registers. The value is updated whenever pulse output rises.

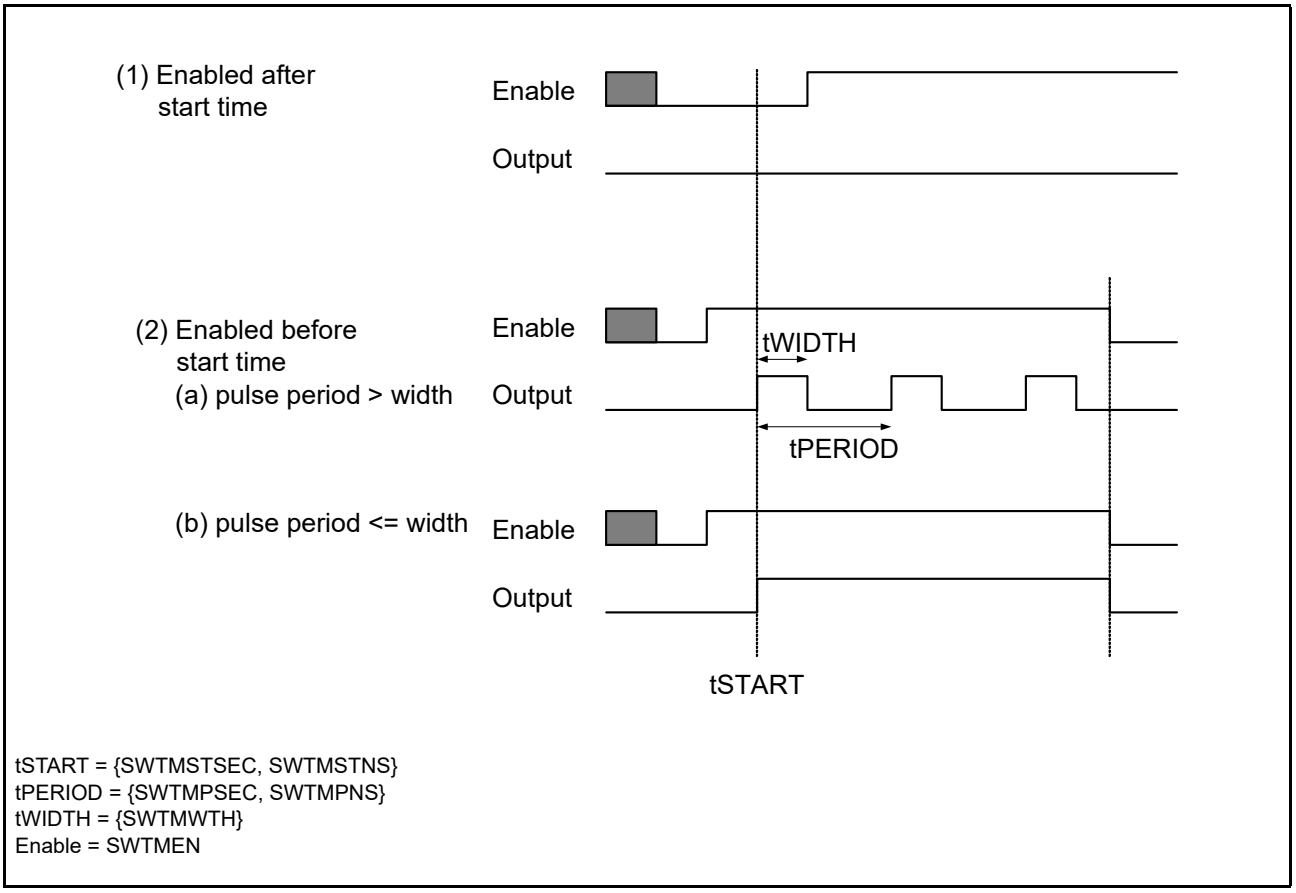

Figure 29.20 Timing Chart of Pulse Signal Generation Function

29.3.4.4 Timestamp Processing

(1) Receive Timestamp Processing

When port 0 or port 1 receives a frame, the timestamp, based on the current time from the timer, is captured when the start of frame delimiter (SFD) is detected at the PHY interface. The timestamp is forwarded together with the frame to the switch module and can be accessed by the internal port (management port) to implement e.g. the Precision-Time-Protocol (PTP). The timestamp information is encapsulated in the dedicated tag in the frames.

(2) Transmit Timestamp Processing

When a frame is transmitted from port 0 or port 1 to the PHY, the timestamp is also captured. The outgoing timestamp can be stored in the port specific timestamp register (PORTn_TIME) for each port. The internal port adds special control information to each frame to limit frames for outgoing timestamp capture, as timestamps must only be captured for dedicated event frames, not for all frames.

29.3.4.5 Transparent Clock Support

(1) General

The hardware implements the necessary functions to implement so-called transparent clocks (TC) for the end-to-end variant.

(2) Implementation of Correction Field Update

The correction field within outgoing Layer 2 PTP frames (i.e. frames with type 0x88F7) can be updated automatically. PTP messages within UDP/IP frames are not automatically updated.
The module that updates the correction field only processes event messages. To detect event messages, frames with the message type field found within the PTP header (type < 4) are extracted. This means that follow-up frames which are not event frames are not processed. Therefore, any correction field detected in the corresponding SYNC frame will be updated automatically. This allows supporting correction field update by one-step as well as two-step master and slave nodes.
For an end-to-end implementation, the correction field of SYNC and DELAY_REQ messages is updated only with the transient time (output time - input time).
Correction field updates occur only on frames that are exchanged between port 0 and port 1. Any frame transmitted from and to the internal port will not be modified.

29.3.5 Frame Tag Dedicated to Management Port (Internal Port)

Information related to frames such as control and timestamp information needs to be delivered between the Ethernet switch and internal Ethernet MAC. Such information can be added to frames as a management tag. The frames with the tag can be transmitted between the Ethernet switch and internal Ethernet MAC. The frames with the tag are used only for transfers between the Ethernet switch and internal Ethernet MAC and once accepted on the receiving side, the information in the tag is acquired. Then the tag is removed.

29.3.5.1 Format of Management Tag

The information of control and timestamp is added into a frame right after the frame source address field as a frame type tag (programmable with a given value). If the tag is added to the position before any other tag (VLAN tag), if exists. The tag includes the following information:

- ControlTag: Identifier that indicates the additional control data is present within the frame. Defined by the ETHSWMTC register and its size is 2 octets.
- ControlData: Control information of the frame. The size is 2 octets.
- ControlData2: Specifies timestamp information on reception and transmit port on transmission. The size is 4 octets.

The original frame follows the ControlData2. For example, any VLAN tags will be found after ControlData2.

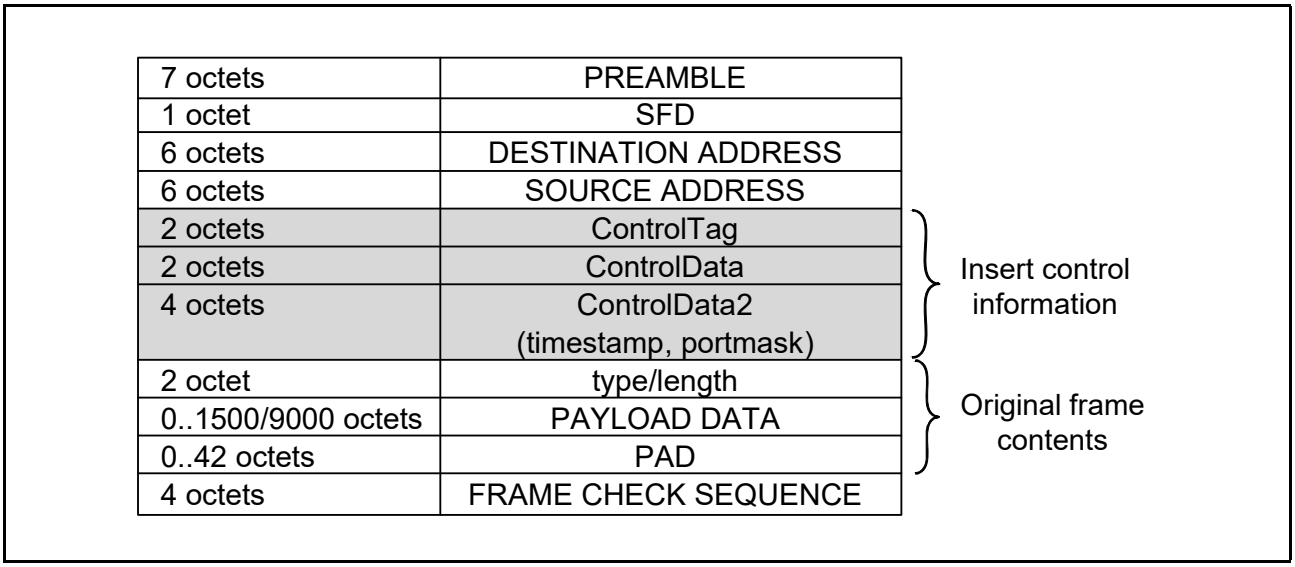

Figure 29.21 Format of Frame with Management Tag in Internal Port

Once a tag is added to a frame, the CRC is recalculated and a new CRC replaces the original CRC received with the frame.
The first octet of ControlData is the more significant byte (bits 15:8) and the 2nd octet of ControlData is the less significant byte (7:0). The first octet of ControlData2 is the more significant byte (bits 31:24) and the 4th octet of ControlData2 is the less significant byte (7:0).

29.3.5.2 Transmit Processing (from Switch to Internal Ethernet MAC)

When the switch forwards a frame to the internal Ethernet MAC, the following information is added into all frames when the tag function has been enabled through bit 31 in register ETHSWMTC.

Table 29.19 Management Frame Tag (During Transfer from Switch to Internal Ethernet MAC)

Field	Bit	Description
ControlData	0	Indicates the number of the external port from which the frame was received. 0: Port 0 1: Port 1
	15 to 1	Reserved
ControlData2	31 to 0	Indicate received timestamp of the frame. The 32-bit nanoseconds value when the SFD of the frame was detected on the port from which the frame was received.

29.3.5.3 Receive Processing (from Internal Ethernet MAC to Switch)

When the internal Ethernet MAC forwards a frame to the switch, the internal Ethernet MAC adds the following information to all frames when the tag function has been enabled through bit 31 in register ETHSWMTC. Once the switch receives the frame with a management tag, it removes the tag from the frame after acquiring the tag contents.

Table 29.20 Management Frame Tag (During Transfer from Switch to Internal Ethernet MAC)

Field	Bit	Description
ControlData	0	Specifies forced forwarding. 0: Forced forwarding is disabled: The frame is forwarded normally. 1: Forced forwarding is enabled: The frame is forwarded to all ports defined in bits 1 and 0 in ControlData2.
	1, 2	Reserved
	3	Marks frame for outgoing timestamping. When set, the frame transmit timestamp will be latched into the corresponding port's transmit timestamp register PORTn_TIME, when the frame is transmitted.
	15 to 4	Reserved
ControlData2	1, 0	Set a destination port mask. Relevant only if ControlData forced forwarding bit (bit 0) is set. Specify the port to which the frames are transferred. Simultaneous forced forwarding to multiple ports is possible. Bit 0 is for port 0 and bit 1 is for port 1. The bits can set: 0: Frame is not forwarded forcibly to the port. 1: Frame is forwarded forcibly to the port.
	31 to 2	Reserved

29.3.5.4 Setting Management Tag Function

The tag insertion or removal function is enabled with register ETHSWMTC. When enabled, a tag inserted automatically to all frames transferred from the switch to the internal Ethernet MAC as well as those transmitted from the internal Ethernet MAC to the switch. When the switch finds any tag, it acquires the tag information and removes the tag for normal transmit processing.

Note: The tag identifier must be configured to a value (e.g. value after reset: E001h) which is not used in the network. For handling management tags in the internal Ethernet MAC, see section 28, Ethernet MAC (ETHERC).

29.4 Overview of Control Software

29.4.1 Overview

The Ethernet switch is the hardware to forward frames between ports. During the forwarding processing, MAC destination address is searched and frames that requires special specific forwarding such as BPDU are filtered. Software needs to initialize the switch and executes tasks to operate the switch.
The software that operates the IEEE1588 timestamp and the DLR is necessary, when they are used. In addition, the higher protocol such as spanning tree needs to be implemented as required.
This section describes the most basic procedures required for switch initialization and learning table management to operate the switch.

29.4.2 Switch Initialization

Initialization of the Ethernet switch includes the following steps.

- Make settings in the MSTPCRB register for release from the module-stop state and reset the Ethernet switch.
- Clear the address table.
- Configure the management (internal) port
- Enable switch ports.
- Enable the MACs on ports.
- Configure the hub module.
- Configure the timer module.
- Configure the DLR module.

Table 29.21 shows examples of initial settings of the address table. Table 29.22 shows examples of initial settings at least required for switch operation. As to the timer module, correction is not performed, the DLR module is also in disable state. For these, set appropriate values in higher-level protocols such as PTP and DLR.

Table 29.21 Examples of Initial Settings of Address Table

Address	Register	Setting Example	Description
A00C 4000h to A00C 47FCh (4-byte units)	ADR_TABLE	0000 0000h	Initializes all entries to 0 in the address table.
A00C 4000h + Hash value of Unicast MAC address×8h	ADR_TABLE	0403 0201h	Sets a unicast address as a static entry. The setting example is when the MAC address is 01-02-03-04-05-06. Only mask port 2 with priority 0. Setting is not required when set dynamically.
Address above +4h	ADR_TABLE	0083 0605h	

Table 29.22 Examples of Initial Settings of Switch Engine

Address	Register	Setting Example	Description
A00B F110h	ETHSWMTC	0000 E001h	Does not use a management tag. Set the register to 8000 E001h when use it. Release the protection using the system protect command register when writing to this register.
A00B F114h	ETHSWMD	0000 0000h	Sets the mode of 10/100 Mbps full-duplex. Release the protection using the system protect command register when writing to this register.
A00B F118h	ETHSFTRST	0000 0006h	Releases the Ethernet switch module and the PHYRESET# pin from the reset state. When writing to this register, protection must be unlocked by using the protect command register.
A00C 000Ch	UCAST_DEFAULT_MASK	0000 0007h	Set the forwarding mask for unknown unicast traffic. When an unknown unicast is received on any port, it is forwarded to all ports set by this mask. When the address table has been initialized, it may be removed from the management (internal) port from the list, which will prevent any unnecessary transfer of unknown unicast the local system. However, this requires the local system's unicast address is set in the address table (i.e. either set during initialization statically, or change the mask setting after at least one frame was sent from the local system and dynamically activate the learning function).
A00C 0014h	BCAST_DEFAULT_MASK	0000 0007h	Specifies all ports to which a broadcast frame will be forwarded.
A00C 0018h	MCAST_DEFAULT_MASK	0000 0007h	Specifies all ports to which a multicast frame will be forwarded, if the address is not found in the address table.
A00C 0020h	MGMT_CONFIG	000 0042h	Enables reception of BPDU frames (bit 6 = 1) and forward the frames to the management port (port 2). If management frames should be discarded, bit 7 should be set.
A00C 0100h A00C 0104h A00C 0108h	VLAN_PRIORITY0 VLAN_PRIORITY1 VLAN_PRIORITY2	006D B688h	Map VLAN priority into the 4 queues available for each port. In this setting, priorities 0 to 3 into queues 0 to 3 and priorities 4 to 7 all into queue 3.
A00C 0180h A00C 0184h A00C 0188h	PRIORITY_CFG0 PRIORITY_CFG1 PRIORITY_CFG2	000 0001h	Enable mapping of the output queue by VLAN priority classification for each port and set default port priority to 0.
A00C 0080h	OQMGR_STATUS	0000 0000h	Enables the output queue. Since bit 1 is set to 1 during the initialization of the memory cell, if bit1 becomes 0, the register should be cleared to 0.
A00C 0088h	QMGR_ST_MINCELLS	0000 0000h	Clears the minimum information of memory free state.
A00C 0094h	QMGR_WEIGHTS	0804 0201h	Sets the weight on the output queue.
A00C 0008h	PORT_ENA	0000 0007h	Enables all ports of the switch.

Table 29.23 Examples of Initial Settings of MAC

Address	Register	Setting Example	Description
A00C 801Ch A00C A01Ch	RX_SECTION_EMPTY0 RX_SECTION_EMPTY1	0000 0000h	The value cannot be changed.
A00C 8020h A00C A020h	RX_SECTION_FULL0 RX_SECTION_FULL1	0000 0000h	The value cannot be changed.
A00C 8024h A00C A024h	TX_SECTION_EMPTY0 TX_SECTION_EMPTY1	0000 0048h	128-stage FIFO has been included in MAC. If an entry to the transmit FIFO exceeds the threshold, the transfer of data from internal to the transmit FIFO stops. It is the threshold to prevent TX overflow. Set the value to 65 or higher.
A00C 8028h A00C A028h	TX_SECTION_FULL0 TX_SECTION_FULL1	0000 0014h	Set the number of entries required for the transmit FIFO to start transmission. Set the value to 17 or higher.
A00C 802Ch A00C A02Ch	RX_ALMOST_EMPTY0 RX_ALMOST_EMPTY1	0000 0008h	The value cannot be changed.
A00C 8030h A00C A030h	RX_ALMOST_FULL0 RX_ALMOST_FULL1	0000 0005h	The value cannot be changed.
A00C 8034h A00C A034h	TX_ALMOST_EMPTY0 TX_ALMOST_EMPTY1	0000 0004h	The value cannot be changed.
A00C 8038h A00C A038h	TX_ALMOST_FULL0 TX_ALMOST_FULL1	0000 0010h	The value cannot be changed.
A00C 8014h A00C A014h	FRM_LENGTH0 FRM_LENGTH1	0000 05F2h	Set the maximum allowable value of the received frame size. For example, set 1522 to respond to a frame with 1 VLAN tag. Also can be set to around 1536 with a margin.
A00C 8008h A00C A008h	COMMAND_CONFIG0 COMMAND_CONFIG1	0580 0013h	Enable the transmission and reception of MAC.

Table 29.24 Examples of Initial Settings of Hub

Address	Register	Setting Example	Description
A00C 01C8h	HUB_FLT_MAC0lo	00C2 8001h	A setting example of the switch management frame such as spanning tree. Filters MAC addresses in 01-80-c2-00-00-{00.3F}.
A00C 01CCh	HUB_FLT_MAC0hi	00C0 0000h	
A00C 01D0h	HUB_FLT_MAC1lo	0019 1B01h	A setting example of normal message of PTPv2. Filters MAC addresses in 01-1b-19-00-00-00.
A00C 01D4h	HUB_FLT_MAC1hi	00FF 0000h	
A00C 01D8h	HUB_FLT_MAC2lo	005E 0001h	A setting example of UDP/IP of PTP. Filters MAC addresses in 01-00-5e-00- 01-{80..87}.
A00C 01DCh	HUB_FLT_MAC2hi	00F8 8001h	
A00C 01E0h	HUB_FLT_MAC3lo	005E 0001h	A setting example of management frame. Filters MAC addresses in 01-00-5e-00- 00-{00..03}.
A00C 01E4h	HUB_FLT_MAC3hi	00FC 0000h	
A00C 01E8h	HUB_FLT_MAC4lo	0403 0201h	Set unicast address. A setting example is for 01-02-03-04-05-06.
A00C 01ECh	HUB_FLT_MAC4hi	00FF 0605h	
A00C 01F0h	HUB_FLT_MAC5lo	0000 0000h	A setting example when not in use.
A00C 01F4h	HUB_FLT_MAC5hi	00FF 0000h	
A00C 01F8h	HUB_FLT_MAC6lo	006C 2101h	A setting example of the beacon frame of the DLR. Frames of the MAC address (01-21-6C-00- 00-01) are forced forwarded.
A00C 01FCh	HUB_FLT_MAC6hi	01FF 0100h	
A00C 01C0h	HUB_CONTROL	0000 00AFh	Enables the hub. Set it to 0000 00A0h when not using the hub.

Table 29.25 Examples of Initial Settings of Timer Module

Address	Register	Setting Example	Description
A00C C004h	TSM_CONFIG	0000 300Bh	Enables one second arrival interrupt (bit 2) of the nanosecond-timer and interrupt generation except for test interrupt (bit 4).
A00C C008h	TSM_IRQ_STAT_ACK	0000 301Fh	Clears all interrupts.
A00C C138h	ATIM_SEC	0000 0000h	Initializes the timer. Should be set before ATIME.
A00C C124h	ATIME	0000 0000h	Initializes the timer.
A00C C12Ch	ATIME_EVT_PERIOD	3B9A CA00h	Sets to 1 second.
A00C C134h	ATIME_INC	0000 0808h	Sets the clock period. Correction is not applied.
A00C C130h	ATIME_CORR	0000 0000h	Drift correction is not applied.
A00C C120h	ATIME_CTRL	0000 00A1h	Starts the timer. Correction is not applied.
A00C C020h A00C C028h	PORT0_CTRL PORT1_CTRL	0000 0000h	Clear the timestamp control and status registers.

Table 29.26 Examples of Initial Settings of DLR Module

Address	Register	Setting Example	Description
A00C E000h	DLR_CONTROL	0000 6400h	Sets the clock period of the timeout timer. Disables the DLR function.
A00C E008h	DLR_ETH_TYP	0000 80E1h	Sets EtherType of DLR frame.
A00C E00Ch	DLR_IRQ_CTRL	0000 0000h	Does not generate DLR interrupt.
A00C E010h	DLR_IRQ_STAT_ACK	0000 FFFFh	Clears all interrupt.
A00C E014h	LOC_MAClo	0403 0201h	Set unicast address. A setting example is for 01-02-03-04-05-06.
A00C E018h	LOC_MAChi	0000 0605h	

29.4.3 Address Table Setting

29.4.3.1 Definition of Block Entry of Address Table

When the hardware receives frames, it searches the address table to find the destination port(s) the frame should be forwarded to. Software is not involved in the forwarding process and all frame processing is performed in hardware. Software, however, takes care of the address table initialization and management. This software task does not require a high priority. However, during operations, a low priority software task is required to continually check for learning data and add MAC addresses to the table or delete old entries when they are out of use for a longer time.
The hardware operates on hash values for an immediate search for the address table. A hash value is used directly as starting address to the address table to search for entries. The next 8 entries starting address are targeted for a linear search to find the MAC address. This is a system called “block entry”.
When the address table is small, the individual per-hash blocks of 8 entries do overlap. The hardware however does not distinguish and will always search all 8 entries starting with the first entry that is pointed to by the hash value. This allows efficient storage in a smaller table without the need to reduce the per hash entries available in a block.
Figure 29.22 shows the principle of the address table layout. The software designer needs to understand this when writing the learning and aging functions.

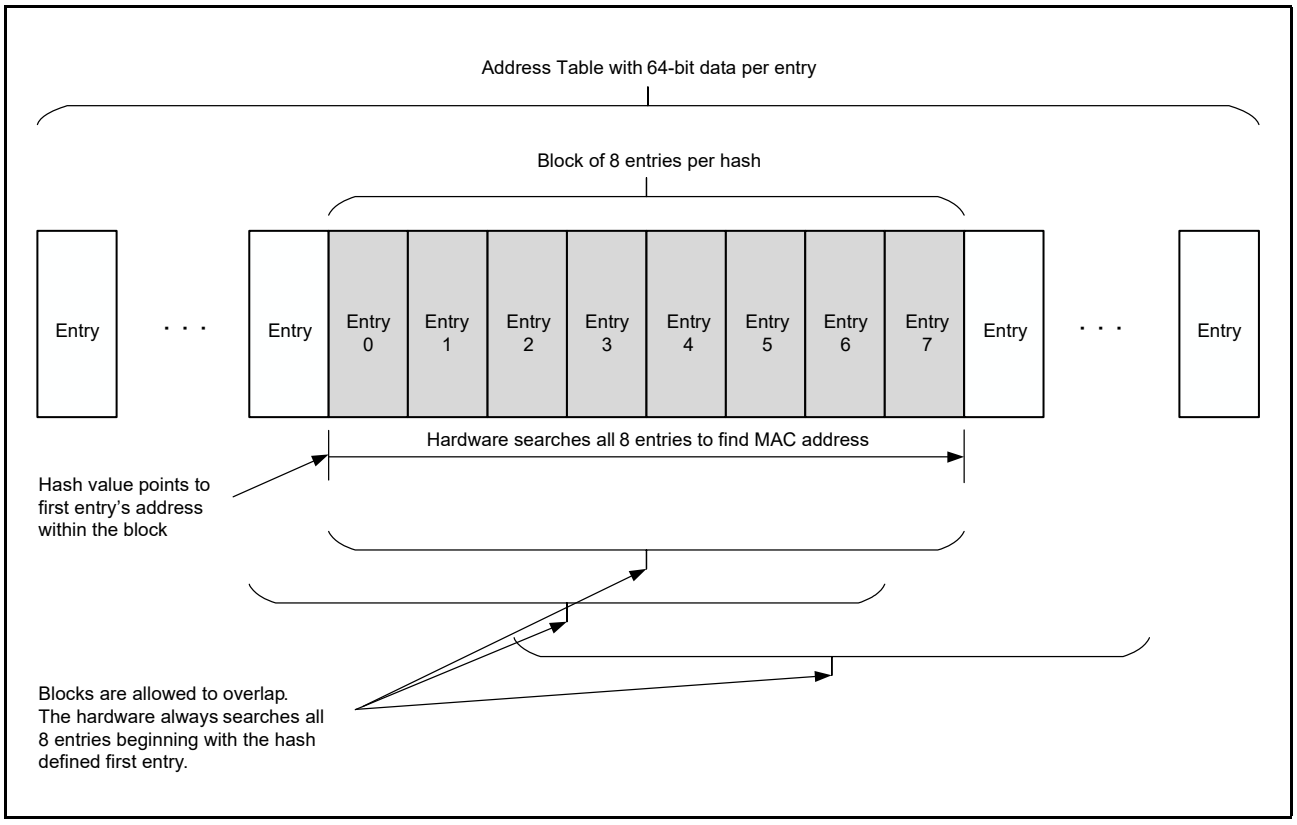

Figure 29.22 Entries of Address Table and Definition of Hash Block

29.4.3.2 Address Learning

The address table is used by the switch forwarding hardware to understand at which destination ports the frame must be transmitted. The hardware automatically looks into the table when it receives frames to determine its destinations. The software is responsible for keeping the table current and inserting the forwarding information that is then used by the hardware.

The software learning function is a low priority background task, which continuously keeps inspecting the learning data (retrieving source address and port number of received frames) and updates the address table whenever a new address is found.

Learning includes the following steps:

- Read data from the learning interface (through registers LRN_REC_A and LRN_REC_B): The data records include a hash value, which is used as the start address where the entries in the address table should be found.
- From the hash-generated start address, search through the 8 entries and update the aging time if the entry is already in the table (or update the port number to implement migration).
- If the entry is not found in any of the 8 entries in the address table, the entry is a new entry that must be added. Adding a new entry is either done into an unused position of the 8 entries, or overwriting a current entry (e.g. random, or the oldest).

Figure 29.23 shows the individual steps in learning and how an address table control function should be implemented. Implement the address learning task with reference to this flowchart.

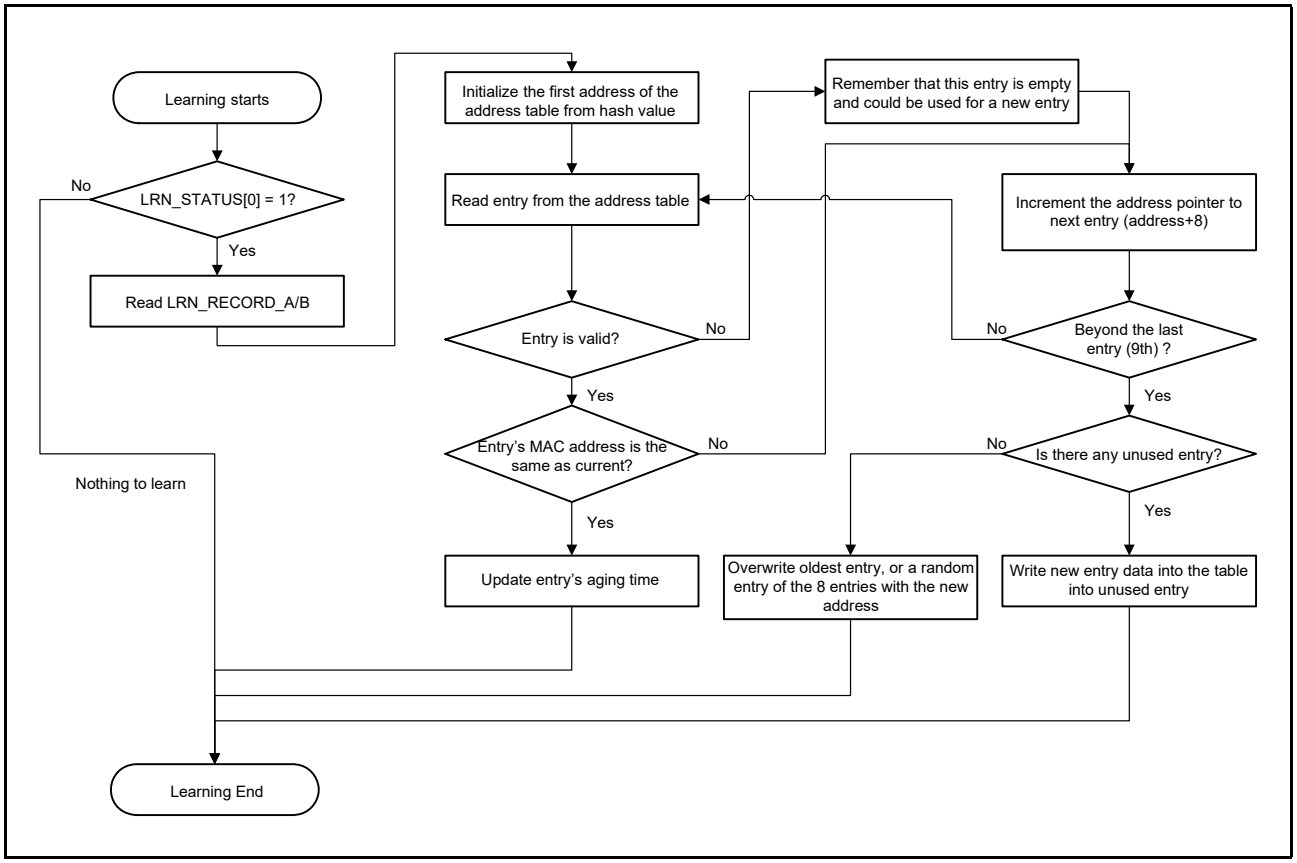

Figure 29.23 Address Learning Flow

29.4.4 Setting of Module Stop Function

Ethernet switch functions are stopped at the initial state. To use any of these functions, set the MSTPCRB.MSTPCRB14 bit and release the module stop function. Note that setting the module stop function again after releasing the function is prohibited. Operations after the second release of the function is not guaranteed. It is possible to release the module stop function after returning to the initial state (stop state) by a reset.

30. EtherCAT Slave Controller (optional)

30.1 Overview

The EtherCAT slave controller (ESC) uses an EtherCAT Slave Controller IP Core made by Beckhoff Automation GmbH, Germany.
The ESC handles EtherCAT communications as an interface between the EtherCAT field bus and slave applications.

Table 30.1 Specification of the EtherCAT Slave Controller

Item	Description
Number of ports	2
FMMU	8
SyncManager	8
Process data RAM [Kbyte]	8
Distributed clocks	64 bits
EBus	No
Process data interfaces (PDI)	
Digital I/O	No
SPI slave	No
Host MPU interface	On-chip bus

Figure 30.1 is a block diagram of the EtherCAT slave controller.
This section describes the function of the registers and modules in white. The registers and modules in gray are described in section 28, Ethernet MAC (ETHERC) and section 29, Ethernet Switch. Refer to the related sections regarding the registers and modules which are needed to operate the EtherCAT slave controller.

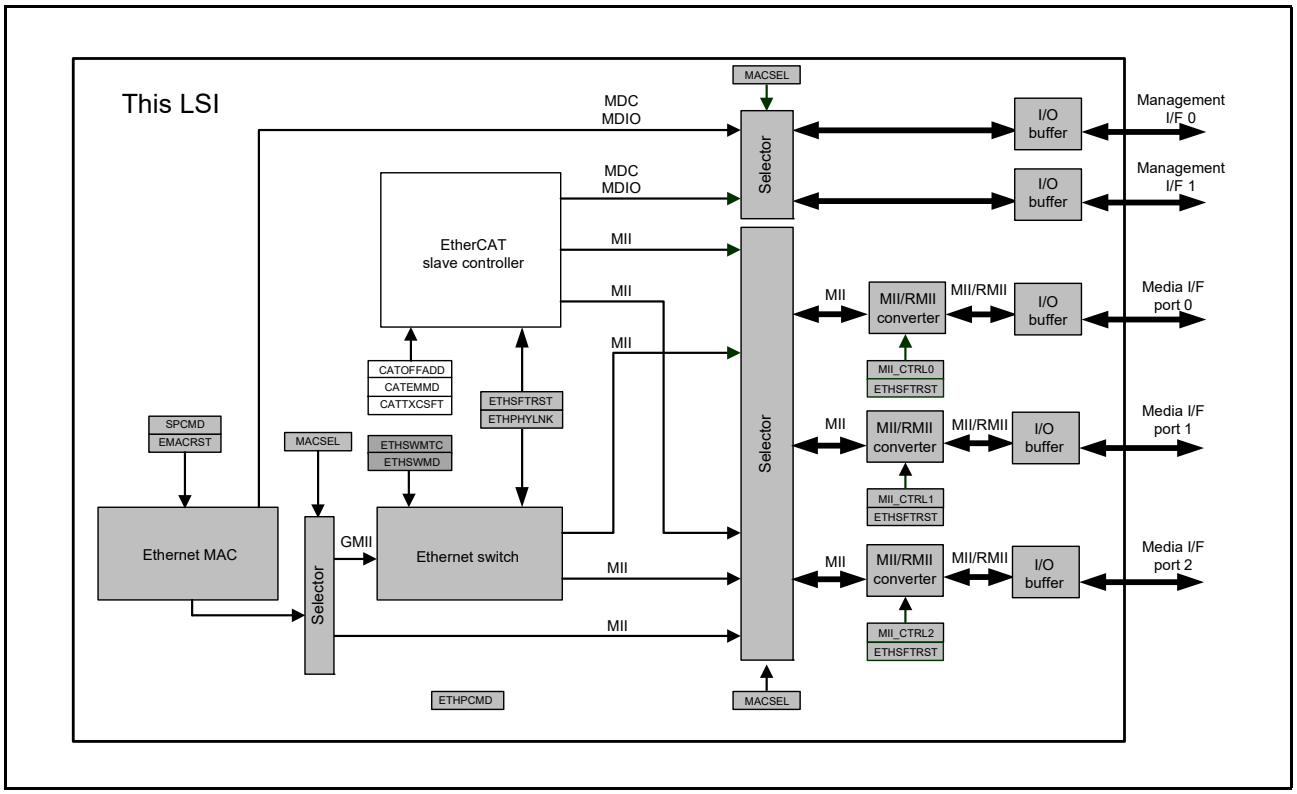

Figure 30.1 Block Diagram of the EtherCAT Slave Controller

Table 30.2 lists the input/output pins of the EtherCAT controller.

Table 30.2 Input/Output Pins of the EtherCAT Slave Controller (excluding PHY MII pins)

Pin Name	I/O	Function	Active
CATLEDRUN	O	EtherCAT RUN LED signal output port	High
CATIRQ	O	EtherCAT IRQ signal output port	High
CATLEDSTER	O	EtherCAT Dual-color State LED signal output port	High
CATLEDERR	O	EtherCAT Error LED signal output port	High
CATLINKACT0	O	EtherCAT link / Activity LED signal output port (port 0)	High
CATLINKACT1	O	EtherCAT link / Activity LED signal output port (port 1)	High
CATSYNC0	O	EtherCAT SYNC0 signal output port	High
CATSYNC1	O	EtherCAT SYNC1 signal output port	High
CATLATCH0	I	EtherCAT LATCH0 signal input port	High
CATLATCH1	I	EtherCAT LATCH1 signal input port	High
CATI2CCLK	O	EtherCAT EEPROM I2C clock output port	—
CATI2CDATA	I/O	EtherCAT EEPROM I2C data signal I/O port	—

30.2 Functional Overview

Typical functions of the EtherCAT slave controller and supported functions by this LSI are shown below. Regarding the detailed specification of EtherCAT and ESC, refer to the documentation (ETG.1000 EtherCAT Specification, etc.) provided by EtherCAT Technology Group (ETG) and the EtherCAT Slave Controller IP Core (v2.04) data sheet provided by Beckhoff Automation.

Table 30.3 Typical Functions of EtherCAT Slave Controller and Supported Functions by this LSI (1 / 3)

Features	Functions	Support
EtherCAT protocol	Handling the following frames: • Ethernet frames with Ether type 88A4h • EtherCAT frames encapsulated in UDP/IP • EtherCAT frames with VLAN Tag • Normal Ethernet frames	√
Addressing modes	Device addressing • Auto increment address • Configured station address • Broadcast address	√
	Logical addressing	√
Working counter	Counting the number of read/write from/to the device	√
EtherCAT command type	Processing the command that master requests slaves to address each addressing mode	√
Loop control	Loop control and loop state in ESC	√
Shadow buffer	Shadow buffers function when register is read/written	√
Circulating frames	Processing of circulating frames during the failure	√
Link detection	Link MII signal (PHY link signal) (monitoring the PHY register via the management interface)	√
	MI Link detection and configuration	—
	Enhanced link detection (monitoring the state of transfer by MII RX error monitor)	√
FIFO size reduction	RX FIFO size reduction because of reduction of propagation delay	√
Ethernet physical layer	MII	√
	EBUS	—
	Back-to-Back MII connection	√
	MII management interface	√
	Read/write of the PHY register via MII management interface	√
	PHY address offset	√
	Manual TX clock shift compensation	√
	Automatic TX clock shift compensation	√
FMMU	Mapping between logical address and physical address	√
SyncManager	Buffer mode	√
	Mailbox mode	√
	Interrupt and latch event generation when a buffer was completely and successfully written or read.	√
	Repeating mailbox communication	√
	SyncManager deactivation by the PDI	√

Table 30.3 Typical Functions of EtherCAT Slave Controller and Supported Functions by this LSI (2 / 3)

Features	Functions	Support
Distributed clocks	Clock Synchronization considering propagation delay and drift compensation	√
	Generation of synchronous output signals (SYNC0 and 1 signals) • Cyclic mode • Single shot mode • Cyclic acknowledge mode • Single shot acknowledge mode	√
	Precise time stamping of input events (LATCH0 and 1 signals) • Single event mode • Continuous mode • SyncManager event mode (for debugging)	√
	Generation of synchronous interrupts	√
	Synchronous digital output updates / Synchronous digital input sampling	—
	Exclusive control for the SYNC and LATCH signals of the ECAT and PDI	√
	System time control by the PDI	—
	Communication Timing • Free run • Synchronized to output event • Synchronized to SYNC signal	√
EtherCAT state machine	Control of state machine / Indication of the status and error code	√
	Device emulation	—
SII EEPROM	SII EEPROM commands	√
	SII EEPROM error indication	√
	SII EEPROM access interface	√
	EEPROM size selection	√
	EEPROM emulation	—
Interrupt	AL event request (PDI interrupt)	√
	ECAT event request (ECAT interrupt)	√
Watchdog	Process data watchdog	√
	PDI watchdog	√
Error counters	Port error counters	√
	Forwarded RX error counter	√
	ECAT processing unit error counter	√
	PDI error counter	√
	Lost link counter	√
	Watchdog counter process data	√
	Watchdog counter PDI	√
LED signals	RUN LED signal	√
	ERR LED signal	√
	STATE LED and STATE_RUN LED signals	√
	LINK/ACT LED signals	√
	Port error LED signal	—
	RUN/ERR LED override	√

Table 30.3 Typical Functions of EtherCAT Slave Controller and Supported Functions by this LSI (3 / 3)

Features	Functions	Support
Process data interface (PDI)	Digital I/O	—
	SPI slave	—
	8-bit/16-bit synchronous/asynchronous microcontroller interface	—
	On-chip bus	√
	General purpose I/O	—
Write protection	Write protection for the register area (0000h to 0FFFh)	√
	Write protection for the whole area including the user RAM and process data RAM (0000h to 2FFFh)	√
ESC reset	ESC reset from the master or PDI	√

30.3 Description of Registers

30.3.1 EtherCAT PHY Offset Address Setting Register (CATOFFADD)

This register sets the offset address of the Ethernet PHY in case of using the EtherCAT.

This register can be read/written in 32-bit units.

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet system protect command register (ETSPCMD). For the ETSPCMD register, see section 28, Ethernet MAC (ETHERC). For the protection unlock procedure, see section 28.2.1.3, Ethernet System Protect Command Register (ETSPCMD). The special sequence is not necessary in case of reading the value of this register.

Address(es): A00B F100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	OADD4	OADD3	OADD2	OADD1	OADD0
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	OADD4 to OADD0	PHY Offset Address Setting	Set the offset address of PHY of using the EtherCAT.	R/W
b31 to b5	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R/W

30.3.2 EtherCAT Operation Mode Setting Register (CATEMMD)

This register sets the EEPROM memory size in case of using the EtherCAT.

This register can be read/written in 32-bit units.

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet system protect command register (ETSPCMD). For the protection unlock procedure, see section 28.2.1.3, Ethernet System Protect Command Register (ETSPCMD). The special sequence is not necessary in case of reading the value of this register.

Address(es): A00B F104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	EEPROMSIZE
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	EEPROMSIZE	EEPROM Memory Size Specification	Sets the size of the EEPROM memory of the EtherCAT. 0: 16 Kbits or less 1: 32 Kbits to 4 Mbits	R/W
b31 to b1	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R/W

30.3.3 EtherCAT TXC Shift Setting Register (CATTXCSFT)

This register controls the delay time of TXC. This register can be read/written in 32-bit units.

Note: This register can only be written when protection is unlocked by the specific sequence using the Ethernet system protect command register (ETSPCMD). For the protection unlock procedure, see section 28.2.1.3, Ethernet System Protect Command Register (ETSPCMD). The special sequence is not necessary in case of reading the value of this register.

Address(es): A00B F10Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b1 to b0	TXSFT01, TXSFT00	ETH0_TXC Delay Time Setting	Set the delay time for ETH0_TXC of the EtherCAT. 00: 0 ns 01: 10 ns 10: 20 ns 11: 30 ns	R/W
b3 to b2	TXSFT11, TXSFT10	ETH1_TXC Delay Time Setting	Set the delay time for ETH1_TXC of the EtherCAT. 00: 0 ns 01: 10 ns 10: 20 ns 11: 30 ns	R/W
b31 to b4	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R/W

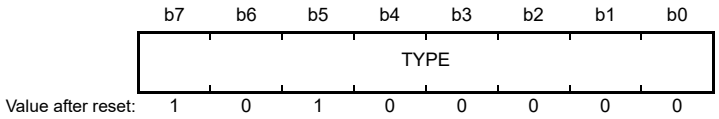
30.4 ESC Information Register

In the tables, ECAT indicates access by the EtherCAT master controller and PDI indicates access by the local CPU.

30.4.1 Type Register (TYPE)

This register indicates the type of the EtherCAT slave controller.

Address(es): A00D 0000h

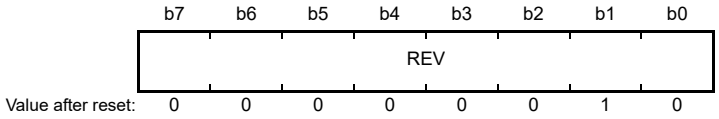


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	TYPE	Slave Controller Type Indication	Type of the EtherCAT slave controller	R	R

30.4.2 Revision Register (REVISION)

This register indicates the revision of the EtherCAT slave controller.

Address(es): A00D 0001h

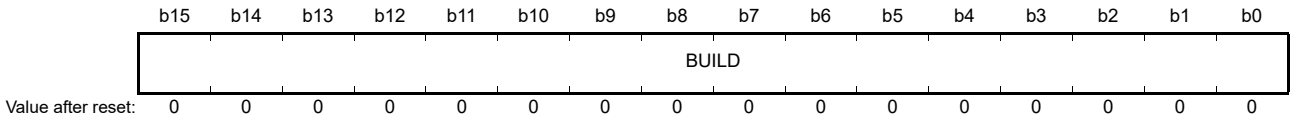


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	REV	Slave Controller Type Indication	Revision of the EtherCAT slave controller	R	R

30.4.3 Build Register (BUILD)

This register indicates the build number of the EtherCAT slave controller.

Address(es): A00D 0002h

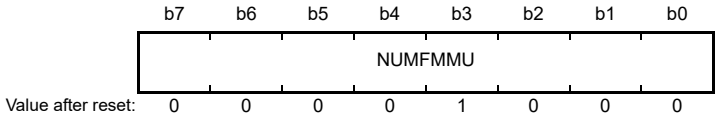


Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	BUILD	Slave Controller Build Number Indication	Build number of the EtherCAT slave controller	R	R

30.4.4 FMMU Supported Register (FMMU_NUM)

This register indicates the number of FMMU channels supported in the EtherCAT slave controller.

Address(es): A00D 0004h

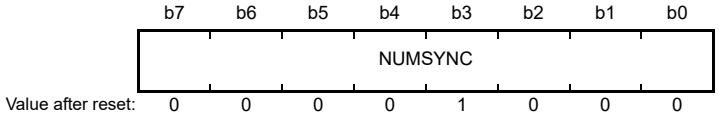


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	NUMFMMU	FMMU Channel Number Indication	Number of FMMU channels supported in the EtherCAT slave controller.	R	R

30.4.5 SyncManager Supported Register (SYNC_MANAGER)

This register indicates the number of SyncManager channels supported in the EtherCAT slave controller.

Address(es): A00D 0005h

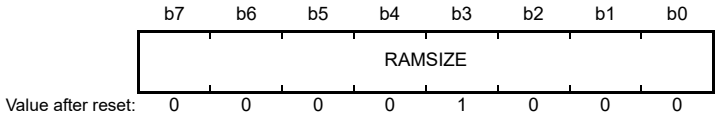


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	NUMSYNC	SyncManager Channel Number Indication	Number of SyncManager channels supported in the EtherCAT slave controller	R	R

30.4.6 RAM Size Register (RAM_SIZE)

This register indicates the process data RAM size supported in the EtherCAT slave controller in Kbyte.

Address(es): A00D 0006h

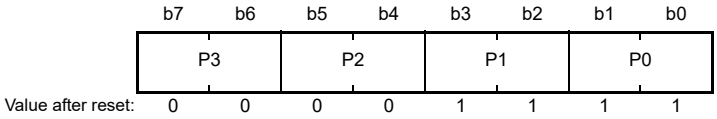


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	RAMSIZE	Process Data RAM Size Indication	Process data RAM size supported in the EtherCAT slave controller (unit: Kbyte)	R	R

30.4.7 Port Descriptor Register (PORT_DESC)

This register indicates the port configuration.

Address(es): A00D 0007h



Bit	Symbol	Bit Name	Description	PDI	ECAT
b1, b0	P0	Port 0 Configuration	Port 0 configuration: Fixed to the setting for MII connection (11) in this LSI. 00: Not implemented 01: Not configured (SII EEPROM) 10: EBUS 11: MII	R	R
b3, b2	P1	Port 1 Configuration	Port 1 configuration: Fixed to the setting for MII connection (11) in this LSI. 00: Not implemented 01: Not configured (SII EEPROM) 10: EBUS 11: MII	R	R
b5, b4	P2	Port 2 Configuration	Port 2 configuration: This LSI does not implement port 2. Fixed to (00). 00: Not implemented 01: Not configured (SII EEPROM) 10: EBUS 11: MII	R	R
b7, b6	P3	Port 3 Configuration	Port 3 configuration: This LSI does not implement port 3. Fixed to (00). 00: Not implemented 01: Not configured (SII EEPROM) 10: EBUS 11: MII	R	R

30.4.8 ESC Features Supported Register (FEATURE)

This register indicates the features supported in the EtherCAT slave controller.

Address(es): A00D 0008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	FSCONFIG	RWSUPP	LRW	DCSYNC	FCS	LINKDECMII	—	—	DCWID	DC	—	FMMU
Value after reset:	x	x	x	x	0	0	0	1	1	1	x	x	1	1	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	FMMU	FMMU Operation Specification	FMMU operation 0: Bit oriented 1: Byte oriented	R	R
b1	—	Reserved	When read, the value returned is undefined.	R	R
b2	DC	Distributed Clock Specification	Distributed clocks 0: Not available 1: Available	R	R
b3	DCWID	Distributed Clock Width Specification	Distributed clocks (width) 0: 32 bits 1: 64 bits	R	R
b5, b4	—	Reserved	When read, the value returned is undefined.	R	R
b6	LINKDECMII	Enhanced Link Detection Specification	Enhanced link detection in MII 0: Not available 1: Available	R	R
b7	FCS	FCS Error Specification	Separate handling of FCS errors 0: Not supported 1: Supported. Frames with wrong FCS and additional nibble will be counted separately in forwarded RX error counter.	R	R
b8	DCSYNC	DC SYNC Specification	Enhanced DC SYNC activation 0: Not available 1: Available	R	R
b9	LRW	LRW Command Support Specification	EtherCAT LRW command support 0: Supported 1: Not supported	R	R
b10	RWSUPP	Command Support Specification	EtherCAT read/write command support (BRW, APRW, FPRW) 0: Supported 1: Not supported	R	R
b11	FSCONFIG	FMMU/SyncManager Specification	Fixed FMMU/SyncManager configuration 0: Variable configuration 1: Fixed configuration	R	R
b15 to b12	—	Reserved	When read, the value returned is undefined.	R	R

30.5 Station Address Registers

30.5.1 Configured Station Address Register (STATION_ADR)

This register indicates the address used for node addressing.

Address(es): A00D 0010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	NODADDR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	NODADDR	Node Addressing Address Indication	Address used for node addressing (FPxx commands)	R	R/W

30.5.2 Configured Station Alias Register (STATION_ALIAS)

This register indicates the alias address used for node addressing (FPxx commands).

Address(es): A00D 0012h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	NODALIADDR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	NODALIADDR	Alias Address Indication	Alias address used for node addressing (FPxx commands). The use of this alias is activated by setting bit 8 of the extended ESC DL control register (ESC_EX_DL_CONTROL at 0102h) to 1.	R/W	R

Note: The initial value, 0, is retained until the EEPROM is loaded. After that, the value becomes the value at address 0004h in the EEPROM. This value is only taken over from the EEPROM the first time the EEPROM is loaded after a power-on or reset.

30.6 Write Protection Registers

30.6.1 Write Register Enable Register (WR_REG_ENABLE)

This register is used to unlock the write protection temporarily while registers are write-protected.

Address(es): A00D 0020h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ENABLE
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ENABLE	Register Write Protection Unlock	When registers are currently being protected against writing (bit 0 is 1 in the write register protection register, WR_REG_PROTECT, at 0021h) and freely writing to registers of the given node is to be permitted, the operation to do so by writing to this register has to proceed in the same Ethernet frame and preceding the other desired writing to registers. Write protection will be reactivated once the frame period elapses (unless the value in the write register protection register is changed).	R	R/W
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

30.6.2 Write Register Protection Register (WR_REG_PROTECT)

This register is used to protect registers against writing. The registers in the area A00D 0000h to A00D 0FFFh are write-protected (except for the WR_REG_ENABLE register (0020h) and ESC_WR_ENABLE register (0030h)).

Address(es): A00D 0021h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PROTECT
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	PROTECT	Register Write Protection Specification	Protection of registers against writing 0: Protection disabled 1: Protection enabled	R	R/W
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

30.6.3 ESC Write Enable Register (ESC_WR_ENABLE)

This register is used to unlock the write protection temporarily while registers and memories are write-protected by ESC write protection.

Address(es): A00D 0030h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ENABLE
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ENABLE	Register/Memory Write Protection Unlock	When registers are currently being protected against writing by ESC write protection (bit 0 is 1 in the ESC write protection register, ESC_WR_PROTECT, at 0031h) and freely writing to registers of the given node is to be permitted, the operation to do so by writing to this register has to proceed in the same Ethernet frame and preceding the other desired writing to registers. Write protection will be reactivated once the frame period elapses (unless the value in the ESC write protection register is changed).	R	R/W
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

30.6.4 ESC Write Protection Register (ESC_WR_PROTECT)

This register is used to protect registers against writing. Registers and memories in the area A00D 0000h to A00D 2FFFh including the process data RAM are write-protected (except for the WR_REG_ENABLE register (0020h) and ESC_WR_ENABLE register (0030h)).

Address(es): A00D 0031h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PROTECT
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	PROTECT	Register/Memory Write Protection Specification	Protection of registers and process memories against writing 0: Protection disabled 1: Protection enabled	R	R/W
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

30.7 Data Link Layer Registers

30.7.1 ESC Reset ECAT Register (ESC_RESET_ECAT)

This register is used to reset the EtherCAT slave controller from the ECAT (master) by software.

When written: ESC_RESET_ECAT_W

Address(es): A00D 0040h

	b7	b6	b5	b4	b3	b2	b1	b0
	RESET_ECAT							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	RESET_ECAT	Software Reset Setting	A reset is enabled after writing 52h (“R”), 45h (“E”) and 53h (“S”) consecutively to this register.	R	R/W

When read: ESC_RESET_ECAT_R

Address(es): A00D 0040h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RESET_ECAT	
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b1, b0	RESET_ECAT	Reset Progress Status	Progress of the reset procedure 01: After writing 52h 10: After writing 45h (if 52h was written before) 00: Others	R	R/W
b7 to b2	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R	R/W

30.7.2 ESC Reset PDI Register (ESC_RESET_PDI)

This register is used to reset the EtherCAT slave controller from the PDI (slave) by software.

When written: ESC_RESET_PDI_W

Address(es): A00D 0041h

	b7	b6	b5	b4	b3	b2	b1	b0
	RESET_PDI							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	RESET_PDI	Software Reset Setting	A reset is enabled after writing 52h (“R”), 45h (“E”) and 53h (“S”) consecutively to this register.	R/W	R

When read: ESC_RESET_PDI_R

Address(es): A00D 0041h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RESET_PDI	
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b1, b0	RESET_PDI	Reset Progress Status	Progress of the reset procedure 01: After writing 52h 10: After writing 45h (if 52h was written before) 00: Others	R/W	R
b7 to b2	—	Reserved	When read, the value returned is undefined.	R	R

30.7.3 ESC DL Control Register (ESC_DL_CONTROL)

This register is used to control loop in the EtherCAT slave controller and configure the RX FIFO size and station alias.

Address(es): A00D 0100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	STAALIAS	—	—	—	—	—	RXFIFO		
Value after reset:	x	x	x	x	x	x	x	0	x	x	x	x	x	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LP3		LP2		LP1		LP0		—	—	—	—	—	—	TEMPUSE	FWDRULE
Value after reset:	1	1	0	0	0	0	0	0	x	x	x	x	x	x	0	1

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	FWDRULE	Forwarding Rule Specification	Forwarding rule 0: EtherCAT frames are processed. Non-EtherCAT frames are forwarded without processing. 1: EtherCAT frames are processed. Non-EtherCAT frames are destroyed. The source MAC address is changed for every frame (SOURCE_MAC[1] is set to 1 (locally administered address)) regardless of the forwarding rule.	R	R/W
b1	TEMPUSE	Temporary Use of Bits 15 to 8	Temporary use of bits 15 to 8 settings 0: Permanent use 1: Use for about 1 second, then revert to previous settings	R	R/W
b7 to b2	—	Reserved	When read, the value returned is undefined.	R	R
b9, b8	LP0	Loop Port 0 Configuration	Loop port 0 configuration 00: Auto 01: Auto close 10: Open 11: Closed	R	R/W
b11, b10	LP1	Loop Port 1 Configuration	Loop port 1 configuration 00: Auto 01: Auto close 10: Open 11: Closed	R	R/W
b13, b12	LP2	Loop Port 2 Configuration	Loop port 2 configuration (port 2 is not available on this LSI.) 00: Auto 01: Auto close 10: Open 11: Closed	R	R/W
b15, b14	LP3	Loop Port 3 Configuration	Loop port 3 configuration (port 3 is not available on this LSI.) 00: Auto 01: Auto close 10: Open 11: Closed	R	R/W
b18 to b16	RXFIFO	RX FIFO Size Specification	Set the RX FIFO size. The transfer time can be reduced by reducing the FIFO size. 0 to 3: Shortened by 40 ns 4 to 6: No change 7: Default	R	R/W
b23 to b19	—	Reserved	When read, the value returned is undefined.	R	R

Bit	Symbol	Bit Name	Description	PDI	ECAT
b24	STAALIAS	Station Alias Status Specification	Station alias 0: Ignore station alias 1: Alias can be used for all configured address command types (FPRD, FPWR, ...).	R	R/W
b31 to b25	—	Reserved	When read, the value returned is undefined.	R	R

Note: Changes to loop configurations are delayed until any current reception or transmission of a frame through the port is completed.
Note: Reducing the size of the Rx FIFO depends on all masters and slaves connected to the same network as the EtherCAT having very precise clock sources. An Rx FIFO size of 7 (default) is sufficient if the precision of all clocks is 100 ppm or better and Rx FIFO sizes of 0 to 3 are possible if the precision is 25 ppm or better.

30.7.4 Physical Read/Write Offset Register (PHYSICAL_RW_OFFSET)

This register is used to set the offset between read address and write address in the R/W commands.

Address(es): A00D 0108h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RWOFFSET															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	RWOFFSET	Offset between Read and Write Addresses	Offset of R/W commands (FPRW, APRW) between read address and write address. That is, in the case of reading, RD_ADR = ADR (the given address is read) In the case of writing, WR_ADR = ADR + R/W offset (writing is to the address obtained by adding the offset set in this register to the given address)	R	R/W

30.7.5 ESC DL Status Register (ESC_DL_STATUS)

This register indicates the state of the EtherCAT slave controller.

Address(es): A00D 0110h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	COMP3	LP3	COMP2	LP2	COMP1	LP1	COMP0	LP0	PHYP3	PHYP2	PHYP1	PHYP0	—	ENHLINKD	PDIWDST	PDIOPE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	x	1	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	PDIOPE	PDI/EEPROM Load State Indication	PDI operation/EEPROM load state 0: EEPROM not loaded, the PDI not operational (process data RAM is not accessible) 1: EEPROM loaded correctly, the PDI operational (process data RAM is accessible)	R	R (ack)
b1	PDIWDST	Watchdog Status	PDI watchdog timer status 0: Timeout of the watchdog timer 1: Watchdog timer reloaded	R	R (ack)
b2	ENHLINKD	Enhanced Link Detection Indication	Enhanced link detection 0: Deactivated for all ports 1: Activated for at least one port Note: This bit is set to the value of bit 9 at address 0000h in the EEPROM the first time the EEPROM is loaded after power is initially supplied or after a reset.	R	R (ack)
b3	—	Reserved	When read, the value returned is undefined.	R	R (ack)
b4	PHYP0	Port 0 Link State Indication	Physical link on port 0 0: No link 1: Link detected	R	R (ack)
b5	PHYP1	Port 1 Link State Indication	Physical link on port 1 0: No link 1: Link detected	R	R (ack)
b6	PHYP2	Port 2 Link State Indication	Physical link on port 2 (port 2 is not available on this LSI.) 0: No link 1: Link detected	R	R (ack)
b7	PHYP3	Port 3 Link State Indication	Physical link on port 3 (port 3 is not available on this LSI.) 0: No link 1: Link detected	R	R (ack)
b8	LP0	Loop Port 0 State Indication	Loop port 0 0: Open 1: Closed	R	R (ack)
b9	COMP0	Port 0 Communication State Indication	Communication on port 0 0: No stable communication 1: Communication established	R	R (ack)
b10	LP1	Loop Port 1 State Indication	Loop port 1 0: Open 1: Closed	R	R (ack)
b11	COMP1	Port 1 Communication State Indication	Communication on port 1 0: No stable communication 1: Communication established	R	R (ack)
b12	LP2	Loop Port 2 State Indication	Loop port 2 (port 2 is not available on this LSI.) 0: Open 1: Closed	R	R (ack)
b13	COMP2	Port 2 Communication State Indication	Communication on port 2 (port 2 is not available on this LSI.) 0: No stable communication 1: Communication established	R	R (ack)

Bit	Symbol	Bit Name	Description	PDI	ECAT
b14	LP3	Loop Port 3 State Indication	Loop port 3 (port 3 is not available on this LSI.) 0: Open 1: Closed	R	R (ack)
b15	COMP3	Port 3 Communication State Indication	Communication on port 3 (port 3 is not available on this LSI.) 0: No stable communication 1: Communication established	R	R (ack)

Note: Reading this register from the ECAT clears bit 2 of the ECAT event request register (ECAT_EVENT_REQ at 0210h).

30.8 Application Layer Registers

30.8.1 AL Control Register (AL_CONTROL)

This register is used to change the state transition of the device state machine and to acknowledge error indication.

Address(es): A00D 0120h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	DEVICEID	ERRINDACK	INISTATE			
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	1

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b3 to b0	INISTATE	State Machine State Change Specification	Change the state transition of the device state machine. 1: Initial state request 3: Bootstrap state request 2: Pre-operational state request 4: Safe-operational state request 8: Operational state request	R (clear)	R/(W)
b4	ERRINDACK	Error Indication Acknowledge	Error indication acknowledge (response) 0: Error Indication in AL status register is not acknowledged. 1: Error Indication in AL status register is acknowledged.	R (clear)	R/(W)
b5	DEVICEID	Device ID Request	Device ID request 0: No request is present. 1: A request is present.	R (clear)	R/(W)
b15 to b6	—	Reserved	When read, the value returned is undefined.	R (clear)	R/(W)

Note: The PDI has to read the AL control register after the ECAT has written it. Otherwise the ECAT cannot write again to the AL control register. Reading the AL control register from the PDI clears bit 0 of the AL event request register (AL_EVENT_REQ at 0220h).

30.8.2 AL Status Register (AL_STATUS)

This register indicates the state of slave application.

Address(es): A00D 0130h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	DEVICEID	ERR	ACTSTATE			
Value after reset:	x	x	x	x	x	x	x	x	x	x	0	0	0	0	0	1

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b3 to b0	ACTSTATE	State Machine State Indication	Actual state of the device state machine 1: Initial state 3: Request bootstrap state 2: Pre-operational state 4: Safe-operational state 8: Operational state	R/(W)	R (ack)
b4	ERR	Error State Indication	Error indicator 0: The device is in the state as requested or flag was cleared by command. 1: The device has not entered the requested state or the state was changed as a result of local action.	R/(W)	R (ack)
b5	DEVICEID	Device ID Load State Indication	Device ID load state 0: Loading the device ID failed. 1: The device ID was loaded.	R/(W)	R (ack)
b15 to b6	—	Reserved	When read, the value returned is undefined.	R/(W)	R (ack)

Note: Reading this register from the ECAT clears bit 3 of the ECAT event request register (ECAT_EVENT_REQ at 0210h).

30.8.3 AL Status Code Register (AL_STATUS_CODE)

This register indicates an error code from slave application.

Address(es): A00D 0134h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	STATUSCODE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	STATUSCODE	Error Code Indication	AL status code	R/W	R

30.8.4 RUN LED Override Register (RUN_LED_OVERRIDE)

This register is used to override control of the RUN LED pin.

Address(es): A00D 0138h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	OVERRIDEEN	LEDCODE			
Value after reset:	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W	PDI	ECAT
b3 to b0	LEDCODE	LED Code Indication	LED code 0h: Off 1h - Ch: Flash 1x - 12x Dh: Blinking Eh: Flickering Fh: On	(FSM state) (1-Init) (4-SafeOp 1x) (2-PreOp) (3-Bootstrap) (8-Op) Note: Bits 3 to 0 of the AL status register (AL_STATUS)	R/W	R/W
b4	OVERRIDEEN	Override Setting	Override enable 0: Override disabled 1: Override enabled		R/W	R/W
b7 to b5	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.		R/W	R/W

Note: Changing the value of the AL status register to an appropriate value will clear bit 4 (override enable).
Normally RUN LED is controlled by the AL status register (AL_STATUS at 0130h) automatically. It is not necessary to override RUN LED in order to indicate the state of a general state machine.
For example, this register can be used to run special lighting patterns that indicate the positions of specific slaves.

30.8.5 ERR LED Override Register (ERR_LED_OVERRIDE)

This register is used to override control of the error LED pin.

Address(es): A00D 0139h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	OVERRIDEEN	LEDCODE			
Value after reset:	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b3 to b0	LEDCODE	LED Code Indication	LED code 0h: Off 1h to Ch: Flash 1x to 12x Dh: Blinking Eh: Flickering Fh: On	R/W	R/W
b4	OVERRIDEEN	Override Setting	Override enable 0: Override disabled 1: Override enabled	R/W	R/W
b7 to b5	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R/W	R/W

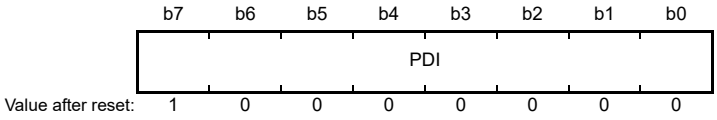
Note: Bit 4 (override enable) will be cleared if a new error occurs.
The ESC automatically controls an error LED under the conditions below. Regarding other errors, the error LED should be controlled by application using this register.
- SII EEPROM load error
- PDI watchdog timeout

30.9 PDI Registers

30.9.1 PDI Control Register (PDI_CONTROL)

This register indicates the type of PDI.

Address(es): A00D 0140h



Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	PDI	PDI Type Indication	Process data interface. In this chip, the below value is indicated. 80h: On-chip bus	R	R

30.9.2 ESC Configuration Register (ESC_CONFIG)

This register indicates configuration of the EtherCAT slave controller.

Address(es): A00D 0141h

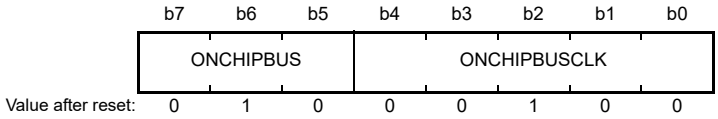
	b7	b6	b5	b4	b3	b2	b1	b0
	ENLP3	ENLP2	ENLP1	ENLP0	DCLATCH	DCSYNC	ENLALLP	DEVEMU
Value after reset:	0	0	0	0	1	1	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	DEVEMU	Device Emulation Setting	Device emulation (control of AL status) 0: The AL status register has to be set by the PDI. 1: The AL status register will be set to a value written to the AL control register.	R	R
b1	ENLALLP	All Ports Enhanced Link Detection Setting	Sets enhanced link detection for all ports. 0: Disabled (if bits 15 to 12 of address 0 in the EEPROM = 0) 1: Enabled at all ports	R	R
b2	DCSYNC	SYNC Output Unit State Indication	Sets the SYNC output unit for distributed clocks (fixed to 1 in this LSI). 0: Disabled (power saving) 1: Enabled	R	R
b3	DCLATCH	Latch Input Unit Setting	Sets the latch input unit for distributed clocks (fixed to 1 in this LSI). 0: Disabled (power saving) 1: Enabled	R	R
b4	ENLP0	Port 0 Enhanced Link Detection Setting	Sets enhanced link detection for port 0. 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R	R
b5	ENLP1	Port 1 Enhanced Link Detection Setting	Sets enhanced link detection for port 1. 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R	R
b6	ENLP2	Port 2 Enhanced Link Detection Setting	Sets enhanced link detection for port 2 (port 2 is not available on this LSI). 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R	R
b7	ENLP3	Port 3 Enhanced Link Detection Setting	Sets enhanced link detection for port 3 (port 3 is not available on this LSI). 0: Disabled (if bit 9 of address 0 in the EEPROM = 0) 1: Enabled	R	R

30.9.3 PDI Configuration Register (PDI_CONFIG)

This register indicates configuration of the PDI.

Address(es): A00D 0150h

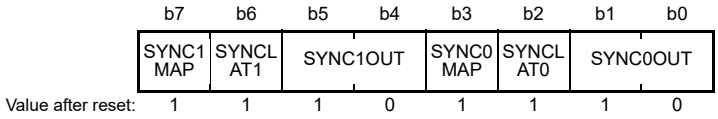


Bit	Symbol	Bit Name	Description	PDI	ECAT
b4 to b0	ONCHIPBUSCLK	On-Chip Bus Clock Indication	Indicate the frequency of the on-chip bus clock. In this chip, the value is always 4 (corresponding to 100 MHz).	R	R
b7 to b5	ONCHIPBUS	On-Chip Bus Type Indication	Indicate the type of on-chip bus. In this chip, the value is always 010.	R	R

30.9.4 SYNC/LATCH PDI Configuration Register (SYNC_LATCH_CONFIG)

This register indicates the configuration of SYNC output and LATCH input.

Address(es): A00D 0151h



Bit	Symbol	Bit Name	Description	PDI	ECAT
b1, b0	SYNC0OUT	SYNC0 Polarity Indication	Indicate the SYNC0 output driver/polarity. In this chip, the value is always 10 (push-pull active high).	R	R
b2	SYNCLAT0	SYNC0/LATCH0 Indication	Indicates the SYNC0/LATCH0 configuration. In this chip, the value is always 1*1. 0: LATCH0 input 1: SYNC0 output	R	R
b3	SYNC0MAP	SYNC0 State Mapping Indication	Indicates enabling or disabling of mapping of the SYNC0 state to bit 2 of the AL event request register (AL_EVENT_REQ at 0220h). This is always enabled in this chip, so the value indicated is always 1 (enabled). 0: Disabled 1: Enabled	R	R
b5, b4	SYNC1OUT	SYNC1 Polarity Indication	Indicate the SYNC1 output driver/polarity. In this chip, the value is always 10 (push-pull active high).	R	R
b6	SYNCLAT1	SYNC1/LATCH1 Indication	Indicates the SYNC1/LATCH1 configuration. In this chip, the value is always 1*1. 0: LATCH1 input 1: SYNC1 output	R	R
b7	SYNC1MAP	SYNC1 State Mapping Indication	Indicates enabling or disabling of mapping of the SYNC1 state to bit 3 of the AL event request register (AL_EVENT_REQ at 0220h). This is always enabled in this chip, so the value indicated is always 1 (enabled). 0: Disabled 1: Enabled	R	R

Note 1. Latch input is available though the value indicates SYNC output. Use the MPC function in order to switch SYNC output to LATCH input and vice versa.

30.9.5 Extended PDI Configuration Register (EXT_PDI_CONFIG)

This register indicates configuration of the PDI.

Address(es): A00D 0152h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	DATABUSWID	
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b1, b0	DATABUSWID	PDI Data Bus Width Indication	Indicate the data bus width of the PDI. In this chip, the value is always 0 (4 bytes). 00: 4 bytes 01: 1 byte 10: 2 bytes 11: Reserved	R	R
b15 to b2	—	Reserved	When read, the value returned is undefined.	R	R

30.10 Interrupt Registers

30.10.1 ECAT Event Mask Register (ECAT_EVENT_MASK)

The ECAT event request (ECAT interrupt) is used to transmit the slave event to the EtherCAT master. This register is used to set mask to each event of the ECAT event request register (ECAT_EVENT_REQ at 0210h). The logical AND of each effective bit in the ECAT event request register and the corresponding bit of this register is taken and the result produces the interrupt signal.

Address(es): A00D 0200h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b15 to b0	ECATEVMASK	Event Request Mask Setting	0: The corresponding bit of the ECAT event request register (ECAT_EVENT_REQ at 0210h) is not mapped. 1: The corresponding bit of the ECAT event request register is mapped.	R	R/W

30.10.2 AL Event Mask Register (AL_EVENT_MASK)

The AL event request (PDI interrupt) is used to transmit the ESC interrupt to the slave application. This register is used to set mask to each event of the AL event request register (AL_EVENT_REQ at 0220h). The logical AND of each effective bit in the AL event request register and the corresponding bit of this register is taken and the result produces the interrupt signal.

Address(es): A00D 0204h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	SMINT 7	SMINT 6	SMINT 5	SMINT 4	SMINT 3	SMINT 2	SMINT 1	SMINT 0	—	WDPD	—	SYNCA CT	DCSYN C1STA	DCSYN C0STA	DCLAT CH	ALCTR L
Value after reset:	0	0	0	0	0	0	0	0	x	0	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ALCTRL	AL Control Event State Indication	AL control event 0: No change in the AL control register 1: The AL control register has been written. This bit is cleared by reading the AL control register (AL_CONTROL at 0120h or 0121h) from the PDI.	R	R
b1	DCLATCH	DC Latch Event State Indication	DC latch event 0: No change on DC latch Inputs 1: At least one change on DC latch inputs This bit is cleared by reading DC latch event times from the PDI for PDI controlled latch units, so the latch 0 and 1 status registers (DC_LATCH_STAT0 and DC_LATCH_STAT1 at 09AEh and 09AFh) indicate no event.	R	R
b2	DCSYNC0STA	DC SYNC0 State Indication	State of DC SYNC0 This bit is cleared by reading the SYNC0 status register (DC_SYNC0_STAT at 098Eh) from the PDI.	R	R
b3	DCSYNC1STA	DC SYNC1 State Indication	State of DC SYNC1 This bit is cleared by reading the SYNC1 status register (DC_SYNC1_STAT at 098Fh) from the PDI.	R	R
b4	SYNCACT	SyncManager Activation Indication	Change of the SyncManager activation register (SMm.ACT at 0806h + 8h*m) 0: No change in any SyncManager 1: At least one SyncManager changed This bit is cleared by reading SyncManager activation registers from the PDI.	R	R
b5	—	Reserved	When read, the value returned is undefined.	R	R
b6	WDPD	Watchdog Process Data Indication	Watchdog process data 0: Valid 1: Timeout This bit is cleared by reading the watchdog status process data register (WDS_DATA at 0440h) from the PDI.	R	R
b7	—	Reserved	When read, the value returned is undefined.	R	R
b8	SMINT0	SyncManager 0 Interrupt Status	SyncManager 0 interrupt (bit 0 or 1 of the SyncManager status register (0805h)) 0: No SyncManager 0 interrupt 1: SyncManager 0 interrupt pending	R	R
b9	SMINT1	SyncManager 1 Interrupt Status	SyncManager 1 interrupt (bit 0 or 1 of the SyncManager status register (080Dh)) 0: No SyncManager 1 interrupt 1: SyncManager 1 interrupt pending	R	R
b10	SMINT2	SyncManager 2 Interrupt Status	SyncManager 2 interrupt (bit 0 or 1 of the SyncManager status register (0815h)) 0: No SyncManager 2 interrupt 1: SyncManager 2 interrupt pending	R	R

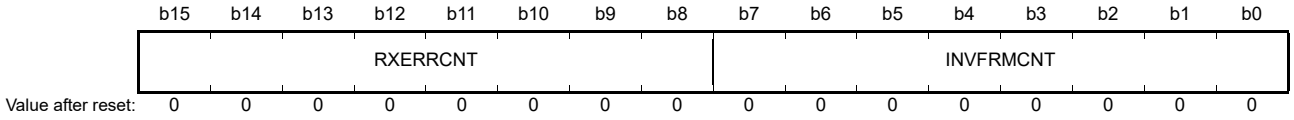
Bit	Symbol	Bit Name	Description	PDI	ECAT
b11	SMINT3	SyncManager 3 Interrupt Status	SyncManager 3 interrupt (bit 0 or 1 of the SyncManager status register (081Dh)) 0: No SyncManager 3 interrupt 1: SyncManager 3 interrupt pending	R	R
b12	SMINT4	SyncManager 4 Interrupt Status	SyncManager 4 interrupt (bit 0 or 1 of the SyncManager status register (0825h)) 0: No SyncManager 4 interrupt 1: SyncManager 4 interrupt pending	R	R
b13	SMINT5	SyncManager 5 Interrupt Status	SyncManager 5 interrupt (bit 0 or 1 of the SyncManager status register (082Dh)) 0: No SyncManager 5 interrupt 1: SyncManager 5 interrupt pending	R	R
b14	SMINT6	SyncManager 6 Interrupt Status	SyncManager 6 interrupt (bit 0 or 1 of the SyncManager status register (0835h)) 0: No SyncManager 6 interrupt 1: SyncManager 6 interrupt pending	R	R
b15	SMINT7	SyncManager 7 Interrupt Status	SyncManager 7 interrupt (bit 0 or 1 of the SyncManager status register (083Dh)) 0: No SyncManager 7 interrupt 1: SyncManager 7 interrupt pending	R	R
b31 to b16	—	Reserved	When read, the value returned is undefined.	R	R

30.11 Error Counter Registers

30.11.1 Rx Error Counter n Register (RX_ERR_COUNTn)

This register counts RX frame errors.

Address(es): A00D 0300h + 0002h*n



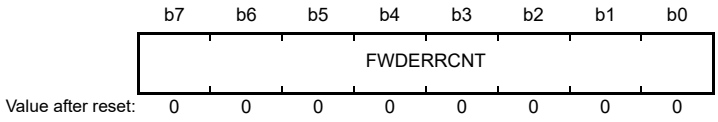
Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	INVFRMCNT	Invalid Frame Counter Value Indication	Counter value of invalid frames for port n Counting is stopped when FFh is reached. These bits are cleared if one of the RX error counters (RX_ERR_COUNTn, FWD_RX_ERR_COUNTn) is written.	R	R/W (clr)
b15 to b8	RXERRCNT	RX Frame Error Counter Value Indication	Counter value of RX errors for port n Counting is stopped when FFh is reached. The number of RX errors of MII interface is counted. These bits are cleared if one of the RX error counters (RX_ERR_COUNTn, FWD_RX_ERR_COUNTn) is written.	R	R/W (clr)

n = 0, 1
n = 0 for port 0; n = 1 for port 1

30.11.2 Forwarded Rx Error Counter n Register (FWD_RX_ERR_COUNTn)

This register counts forwarded RX frame errors.

Address(es): A00D 0308h + 0001h*n



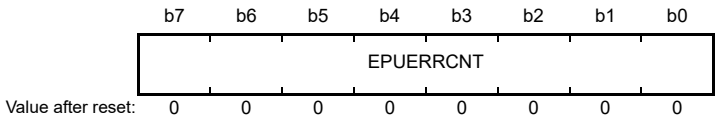
Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	FWDERRCNT	Forwarded Error Counter Value Indication	Counter value of forwarded RX error frames for port n Counting is stopped when FFh is reached. These bits are cleared if one of the RX error counters (RX_ERR_COUNTn, FWD_RX_ERR_COUNTn) is written.	R	R/W (clr)

n = 0, 1
n = 0 for port 0; n = 1 for port 1

30.11.3 ECAT Processing Unit Error Counter Register (ECAT_PROC_ERR_COUNT)

This register counts frame errors passing the ECAT processing unit.

Address(es): A00D 030Ch

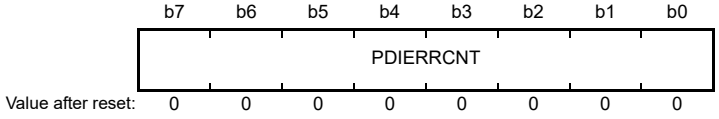


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	EPUERRCNT	Processing Unit Error Counter Value Indication	ECAT processing unit error counter value Counting is stopped when FFh is reached. This register counts errors of frames passing the processing unit. Writing to this register clears it.	R	R/W (clr)

30.11.4 PDI Error Counter Register (PDI_ERR_COUNT)

This register counts PDI access errors.

Address(es): A00D 030Dh

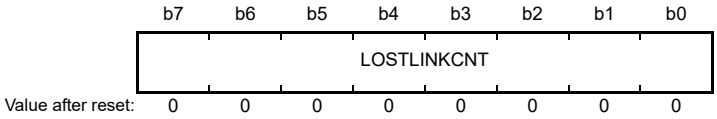


Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	PDIERRCNT	PDI Error Counter Value Indication	PDI error counter value Counting is stopped when FFh is reached. Counting starts when an interface error occurs due to access to the PDI. Writing to this register clears it.	R	R/W (clr)

30.11.5 Lost Link Counter n Register (LOST_LINK_COUNTn)

This register counts lost links at port n.

Address(es): A00D 0310h + 0001h*n



Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	LOSTLINKCNT	Lost Link Counter Value Indication	Lost link counter value for port n Counting is stopped when FFh is reached. Counting starts only when port loop is Auto or Auto-Close. Only lost links at open ports are counted. Writing to one of the lost link counter registers clears it.	R	R/W (clr)

n = 0, 1

n = 0 for port 0; n = 1 for port 1

30.12 Watchdog Registers

30.12.1 Watchdog Divider Register (WD_DIVIDE)

This register is used to set the ratio for dividing 25 MHz to obtain the basic period for incrementing the watchdog timer.

Address(es): A00D 0400h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WDDIV															
Value after reset:	0	0	0	0	1	0	0	1	1	1	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	WDDIV	Watchdog Clock Frequency Divisor Setting	Set the frequency divisor of the clock to drive counting by the watchdog timer in units of ticks at 25 MHz. The clock that drives counting by the watchdog timer is obtained by dividing 25 MHz by the value in this register plus two. The default value is 2498, which corresponds to a period of 100 µs.	R	R/W

30.12.2 Watchdog Time PDI Register (WDT_PDI)

This register is used to set the time until the PDI watchdog timer overflows.

Address(es): A00D 0410h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WDTIMPDI															
Value after reset:	0	0	0	0	0	0	1	1	1	1	1	0	1	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	WDTIMPDI	Watchdog Overflow Time Setting	Set the time until the PDI watchdog timer overflows as a number of times the watchdog is incremented. With the default values for these bits and the setting of the watchdog divider, the time for a single incrementation is 100 µs, so the watchdog timer overflows when 100 µs x 1000 = 100 ms elapse. Setting these bits to 0 disables the watchdog timer. Access to the PDI restarts the watchdog timer.	R	R/W

30.12.3 Watchdog Time Process Data Register (WDT_DATA)

This register is used to set the time until the process data watchdog timer overflows.

Address(es): A00D 0420h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	WDTIMPD															
Value after reset:	0	0	0	0	0	0	1	1	1	1	1	0	1	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	WDTIMPD	Watchdog Overflow Time Setting	Set the time until the process data watchdog timer overflows as a number of times the watchdog is incremented. With the default values for these bits and the setting of the watchdog divider, the time for a single incrementation is 100 µs, so the watchdog timer overflows when 100 µs x 1000 = 100 ms elapse. There is one Watchdog for all SyncManagers. Setting these bits to 0 disables the watchdog timer. Access to the watchdog trigger enable bit of SyncManager restarts the watchdog timer.	R	R/W

30.12.4 Watchdog Status Process Data Register (WDS_DATA)

This register indicates the state of the process data watchdog timer.

Address(es): A00D 0440h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	WDSTAPD
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	WDSTAPD	Watchdog State Indication	Indicates the state of the process data watchdog timer triggered by SyncManagers. 0: The timeout period of the process data watchdog timer elapses. 1: The process data watchdog timer is active or disabled Reading this register clears bit 6 of the AL event request register (AL_EVENT_REQ at 0220h).	R (ack)	R
b15 to b1	—	Reserved	When read, the value returned is undefined.	R (ack)	R

30.12.5 Watchdog Counter Process Data Register (WDC_DATA)

This register indicates the timeout counter value of the process data watchdog timer.

Address(es): A00D 0442h

	b7	b6	b5	b4	b3	b2	b1	b0
	WDCNTPD							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	WDCNTPD	Watchdog Counter Value Indication	Counter value of the process data watchdog timer Counting stops when FFh is reached. Counting starts on a timeout of the process data watchdog timer. Writing to one of the watchdog counter registers (WDC_DATA, WDC_PDI at 0442h and 0443h) clears the counter.	R	R/W (clr)

30.12.6 Watchdog Counter PDI Register (WDC_PDI)

This register indicates the timeout counter value of the PDI watchdog timer.

Address(es): A00D 0443h

	b7	b6	b5	b4	b3	b2	b1	b0
	WDCNTPDI							
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b7 to b0	WDCNTPDI	Watchdog Counter Value Indication	Counter value of the PDI watchdog timer Counting stops when FFh is reached. Counting starts on a timeout of the PDI watchdog timer. Writing to one of the watchdog counter registers (WDC_DATA, WDC_PDI at 0442h and 0443h) clears the counter.	R	R/W (clr)

30.13 SII EEPROM Interface Registers

The EtherCAT controls the SII EEPROM interface if bit 0 is 0 in the EEPROM configuration register (EEP_CONF at 0500h) and in the EEPROM PDI access state register (EEP_PDI_ACCESS at 0501h). Otherwise, the PDI controls the EEPROM interface.

30.13.1 EEPROM Configuration Register (EEP_CONF)

This register is used to configure EEPROM access.

Address(es): A00D 0500h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FORCE ECAT	CTRLP DI
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	CTRLPDI	PDI EEPROM Control	Specifies whether EEPROM control is offered to the PDI. 0: The PDI has no EEPROM control. 1: The PDI has EEPROM control.	R	R/W
b1	FORCEECAT	EEPROM Access Right Change	Forcibly changes the right of access to the EEPROM by the ECAT. 0: No change 1: Reset bit 0 of the EEPROM PDI access state register (EEP_PDI_ACCESS at 0501h) to 0. That is, prohibit access to the EEPROM by the PDI.	R	R/W
b7 to b2	—	Reserved	When read, the value returned is undefined.	R	R

30.13.2 EEPROM PDI Access State Register (EEP_STATE)

This register is used to set the right of access to the EEPROM by the PDI.

Address(es): A00D 0501h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	PDIAC CESS
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	PDIACCESS	EEPROM Access Right Setting	Sets the right of access to the EEPROM. 0: Prohibits the PDI from access to the EEPROM. 1: The PDI has access to the EEPROM. Write access from the PDI is only possible when bit 0 is 1 and bit 1 is 0 in the EEPROM configuration register (EEP_CONF at 0500h).	R/(W)	R
b7 to b1	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R/(W)	R

30.13.3 EEPROM Control/Status Register (EEP_CONT_STAT)

This register is used to control access to the EEPROM and indicate the status.

Address(es): A00D 0502h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BUSY	WRENERR	ACKCMDERR	LOADSTA	CKSUMERR	COMMAND			PROMSIZE	READBYTE	—	—	—	—	—	ECATWREN
Value after reset:	0	0	0	0	0	0	0	0	0	0	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ECATWREN	Write Enable	ECAT write enable*2 0: Write requests are disabled. 1: Write requests are enabled. This bit is always 1 if the PDI has EEPROM control.	R	R/(W)
b5 to b1	—	Reserved	When read, the value returned is undefined.	R	R
b6	READBYTE	EEPROM Read Byte Indication	Indicates supported EEPROM read bytes. 0: 4 bytes 1: 8 bytes	R	R
b7	PROMSIZE	EEPROM Algorithm Indication	Indicates the selected EEPROM algorithm. 0: 1 address byte (1-Kbit to 16-Kbit EEPROMs) 1: 2 address bytes (32-Kbit to 4-Mbit EEPROMs)	R	R
b10 to b8	COMMAND	Command Setting/ Indication	Command*2 Write: Initiates the commands below. Read: Indicates the currently executed command. Commands: 000: No command/EEPROM idle (clear error bits) 001: Read 010: Write 100: Reload Others: Reserved/invalid commands (must not be issued)	R/(W)	R/(W)
b11	CKSUMERR	Checksum Error Indication	Indicates checksum error in the ESC configuration area. 0: No error in the checksum 1: Error in the checksum	R	R
b12	LOADSTA	EEPROM Loading Status Indication	Indicates EEPROM loading status. 0: EEPROM has been loaded and device information has no problem. 1: EEPROM has not been loaded and device information is not available (EEPROM loading in progress or finished with a failure).	R	R
b13	ACKCMDERR	Acknowledge/Command Error Indication	Indicates error acknowledge/command *1 0: No error 1: Missing EEPROM acknowledge or invalid command	R	R
b14	WRENERR	Write Enable Error Indication	Indicates error write enable*1. 0: No error 1: Write command without write enable	R	R
b15	BUSY	EEPROM Interface State Indication	Indicates a busy state of the EEPROM interface. 0: The EEPROM Interface is idle. 1: The EEPROM Interface is busy.	R	R

Write access depends on the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if the EEPROM interface is busy (bit 15 = 1).

Note 1. Error bits are cleared by writing “000” (or any valid command) to command bits b10 to b8.

Note 2. ECAT write enable bit 0 is self-cleared at the SOF of the next frame. Command bits b10 to b8 are also self-cleared after the command is executed (EEPROM busy ends).
Writing “000” to command bits b10 to b8 will also clear the error bits b14 and b13. Command bits b10 to b8 are ignored if the acknowledge/command error bit b13 is 1.

30.13.4 EEPROM Address Register (EEP_ADR)

This register is used to set the EEPROM address to be accessed.

Address(es): A00D 0504h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ADDRESS															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADDRESS															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	ADDRESS	EEPROM Address Setting	EEPROM address 0: First word (= 16 bits) 1: Second word : Actually used EEPROM address bits: [9:0]: EEPROM size of up to 16 Kbits [17:0]: EEPROM size of 32 Kbits to 4 Mbits	R/(W)	R/(W)

Write access depends on the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if the EEPROM interface is busy (bit 15 is 1 in the EEPROM control/status register, EEP_CONT_STAT, at 0502h).

30.13.5 EEPROM Data Register (EEP_DATA)

This register is used to set write data to the EEPROM or indicates read data from the EEPROM. It can be written in 1-word units and read in 2-word units.

Address(es): A00D 0508h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	HIDATA															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LODATA															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	LODATA	EEPROM Write Data Setting	Data to be written to the EEPROM or data read from the EEPROM (lower 2 bytes)	R/(W)	R/(W)
b31 to b16	HIDATA	EEPROM Read Data Indication	Data read from the EEPROM (upper 2 bytes)	R	R

Write access depends on the assignment of the EEPROM interface (ECAT/PDI). Write access is generally blocked if the EEPROM interface is busy (bit 15 is 1 in the EEPROM control/status register, EEP_CONT_STAT, at 0502h).

30.14 MII Management Interface Registers

30.14.1 MII Management Control/Status Register (MII_CONT_STAT)

This register is used to control the MII management interface and to indicate the status.

Address(es): A00D 0510h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	x	x	x	0	0	0	0	0	0	0	0	1	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	WREN	Write Enable	Write enable 0: Disabled 1: Enabled This bit is always 1 if the PDI controls the MII management interface.	R	R/(W)
b1	PDICTRL	PDI Control Indication	Indicates whether the MII management interface can be controlled by the PDI. 0: Only ECAT control 1: PDI control possible The interface is controlled by the MII management ECAT access state register (MII_ECAT_ACS_STAT at 0516h) and the MII management PDI access state register (MII_PDI_ACS_STAT at 0517h).	R	R
b2	MILINK	Link Detection Availability Indication	MI link detection 0: Not available 1: Available	R	R
b7 to b3	PHYOFFSET	PHY Address Offset Indication	Indicate the PHY address offset.	R	R
b9, b8	COMMAND	Command	Command Write: Initiates the commands below. Read: Indicates the currently executed command. Commands: 00: No command/MI idle (clear error bits) 01: Read 10: Write Others: Reserved/invalid commands (must not be issued)	R/(W)	R/(W)
b12 to b10	—	Reserved	When read, the value returned is undefined.	R	R
b13	READERR	Read Error Indication	Indicates whether a read error occurred. 0: No read error 1: Read error occurred (PHY or register not available) This bit is cleared by writing to this register.	R/(W)	R/(W)
b14	CMDERR	Command Error Indication	Indicates whether a command error occurred. 0: Last command was successful 1: Invalid command or write command without write enable This bit is cleared by executing a valid command or writing “00” to command bits 9 and 8.	R	R
b15	BUSY	MII Management State Indication	Indicates that the MII management interface is busy. 0: MII management interface is idle. 1: MII management interface is busy.	R	R

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (b15 in this register = 1).

Note: Write enable bit (b0) is self-cleared at the SOF of the next frame. Command bits (b9 and b8) are also self-cleared after the command is executed (busy ends).
Writing “00” to command bits will also clear the error bits (b14 and b13). Command bits are cleared after the command is executed.

30.14.2 PHY Address Register (PHY_ADR)

This register is used to set the PHY address.

Address(es): A00D 0512h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PHYADDR				
Value after reset:	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b4 to b0	PHYADDR	PHY Address Setting	PHY address	R/(W)	R/(W)
b7 to b5	—	Reserved	When read, the value returned is undefined.	R	R

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 is 1 in the MII management control/status register, MII_CONT_STAT, at 0510h).

30.14.3 PHY Register Address Register (PHY_REG_ADR)

This register is used to set the PHY register address.

Address(es): A00D 0513h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PHYREGADDR				
Value after reset:	x	x	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b4 to b0	PHYREGADDR	PHY Address Setting	Address of PHY register	R/(W)	R/(W)
b7 to b5	—	Reserved	When read, the value returned is undefined.	R	R

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 is 1 in the MII management control/status register, MII_CONT_STAT, at 0510h).

30.14.4 PHY Data Register (PHY_DATA)

This register is used to set data to write to PHY registers or to indicate data read from PHY registers.

Address(es): A00D 0514h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHYREGDATA															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	PHYREGDATA	PHY Register Data Indication/Setting	PHY register read/write data	R/(W)	R/(W)

Write access depends on the assignment of the management interface (ECAT/PDI). Write access is generally blocked if the management interface is busy (bit 15 is 1 in the MII management control/status register, MII_CONT_STAT, at 0510h).

30.14.5 MII Management ECAT Access State Register (MII_ECAT_ACS_STAT)

This register is used to set the right of access to the MII management interface.

Address(es): A00D 0516h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ACSMII
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ACSMII	MII Management Interface Access Right Setting	Right of access to the MII management interface 0: Enables access to the MII management interface by the PDI. 1: Exclusive access to the MII management interface by the ECAT	R	R/(W)
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

Write access is only possible when bit 0 is 1 in the MII management PDI access state register (MII_PDI_ACS_STAT at 0517h).

30.14.6 MII Management PDI Access State Register (MII_PDI_ACS_STAT)

This register is used to set the right of access to the MII management interface.

Address(es): A00D 0517h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FORPDI	ACSMII
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ACSMII	MII Management Interface Access Right Change	Right of access to the MII management interface 0: Access to the MII management interface by the PDI 1: Access to the MII management interface by the ECAT	R/(W)	R
b1	FORPDI	PDI Access State Change	Forced change of access by the PDI (forced change of bit 0) 0: The value of bit 0 of this register is not changed. 1: The value of bit 0 of this register is reset to 0 (the right of access is changed to the ECAT)	R	R/W
b7 to b2	—	Reserved	When read, the value returned is undefined.	R	R

Write access to bit 0 from the PDI is only possible if the following two conditions are satisfied.
- Bit 0 is 0 in the MII management ECAT access state register (MII_ECAT_ACS_STAT at 0516h).
- Bit 1 is 0 in the MII management PDI access state register (MII_PDI_ACS_STAT at 0517h).

30.15 FMMU Registers

30.15.1 FMMU Logical Start Address m Register (FMMUm_L_START_ADR)

This register is used to set the logical start address within the EtherCAT address space for FMMU.

Address(es): A00D 0600h : FMMU0_L_START_ADR
A00D 0610h : FMMU1_L_START_ADR
A00D 0620h : FMMU2_L_START_ADR
A00D 0630h : FMMU3_L_START_ADR
A00D 0640h : FMMU4_L_START_ADR
A00D 0650h : FMMU5_L_START_ADR
A00D 0660h : FMMU6_L_START_ADR
A00D 0670h : FMMU7_L_START_ADR

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LSTAADR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LSTAADR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	LSTAADR	Logical Start Address Setting	Set the start of the logical address within the EtherCAT address space.	R	R/W

m = 0 to 7

30.15.2 FMMU Length m Register (FMMUm_LEN)

This register is used to set the length for FMMU area in byte units.

Address(es): A00D 0604h : FMMU0_LEN
A00D 0614h : FMMU1_LEN
A00D 0624h : FMMU2_LEN
A00D 0634h : FMMU3_LEN
A00D 0644h : FMMU4_LEN
A00D 0654h : FMMU5_LEN
A00D 0664h : FMMU6_LEN
A00D 0674h : FMMU7_LEN

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FMMULEN															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	FMMULEN	Area Size Specification	Set the area size in byte units. Address at the end of the logical address range set by the FMMU minus the address at the start of the logical address range set by the FMMU plus one	R	R/W

m = 0 to 7

30.15.3 FMMU Logical Start Bit m Register (FMMUm_L_START_BIT)

This register is used to set the start bits of the logical start address for FMMU.

Address(es): A00D 0606h : FMMU0_L_START_BIT
A00D 0616h : FMMU1_L_START_BIT
A00D 0626h : FMMU2_L_START_BIT
A00D 0636h : FMMU3_L_START_BIT
A00D 0646h : FMMU4_L_START_BIT
A00D 0656h : FMMU5_L_START_BIT
A00D 0666h : FMMU6_L_START_BIT
A00D 0676h : FMMU7_L_START_BIT

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	LSTABIT		
Value after reset:	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b2 to b0	LSTABIT	Start Bit Setting	Set the start bits of the logical start address for FMMU.	R	R/W
b7 to b3	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

30.15.4 FMMU Logical Stop Bit m Register (FMMUm_L_STOP_BIT)

This register is used to set the last bits of the logical end address for FMMU.

Address(es): A00D 0607h : FMMU0_L_STOP_BIT
A00D 0617h : FMMU1_L_STOP_BIT
A00D 0627h : FMMU2_L_STOP_BIT
A00D 0637h : FMMU3_L_STOP_BIT
A00D 0647h : FMMU4_L_STOP_BIT
A00D 0657h : FMMU5_L_STOP_BIT
A00D 0667h : FMMU6_L_STOP_BIT
A00D 0677h : FMMU7_L_STOP_BIT

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	LSTPBIT		
Value after reset:	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b2 to b0	LSTPBIT	Last Bit Setting	Set the last bits of the logical end address for FMMU.	R	R/W
b7 to b3	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

30.15.5 FMMU Physical Start Address m Register (FMMUm_P_START_ADR)

This register is used to set the physical start address of the ESC to which the logical start address will be mapped by the FMMU.

Address(es): A00D 0608h : FMMU0_P_START_ADR
A00D 0618h : FMMU1_P_START_ADR
A00D 0628h : FMMU2_P_START_ADR
A00D 0638h : FMMU3_P_START_ADR
A00D 0648h : FMMU4_P_START_ADR
A00D 0658h : FMMU5_P_START_ADR
A00D 0668h : FMMU6_P_START_ADR
A00D 0678h : FMMU7_P_START_ADR

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PHYSTAADR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	PHYSTAADR	Physical Start Address Setting	Set the physical start address to which the logical start address will be mapped. The address is set as an offset from the base address (A00D 0000h).	R	R/W

m = 0 to 7

30.15.6 FMMU Physical Start Bit m Register (FMMUm_P_START_BIT)

This register is used to set the start bits of the physical start address of the ESC to which the start bits of the logical start address will be mapped by the FMMU.

Address(es): A00D 060Ah : FMMU0_P_START_BIT
A00D 061Ah : FMMU1_P_START_BIT
A00D 062Ah : FMMU2_P_START_BIT
A00D 063Ah : FMMU3_P_START_BIT
A00D 064Ah : FMMU4_P_START_BIT
A00D 065Ah : FMMU5_P_START_BIT
A00D 066Ah : FMMU6_P_START_BIT
A00D 067Ah : FMMU7_P_START_BIT

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PHYSTABIT		
Value after reset:	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b2 to b0	PHYSTABIT	Physical Start Bit Setting	Set the start bits of the physical start address to which the start bits of the logical start address will be mapped.	R	R/W
b7 to b3	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

30.15.7 FMMU Type m Register (FMMUm_TYPE)

This register is used to set the type of FMMU access.

Address(es): A00D 060Bh : FMMU0_TYPE
A00D 061Bh : FMMU1_TYPE
A00D 062Bh : FMMU2_TYPE
A00D 063Bh : FMMU3_TYPE
A00D 064Bh : FMMU4_TYPE
A00D 065Bh : FMMU5_TYPE
A00D 066Bh : FMMU6_TYPE
A00D 067Bh : FMMU7_TYPE

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	WRITE	READ
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	READ	Read Access Mapping Setting	Sets the mapping for read access. 0: Disabled 1: Enabled	R	R/W
b1	WRITE	Write Access Mapping Setting	Sets the mapping for write access. 0: Disabled 1: Enabled	R	R/W
b7 to b2	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

30.15.8 FMMU Activate m Register (FMMUm_ACT)

This register is used to enable or disable FMMU.

Address(es): A00D 060Ch : FMMU0_ACT
A00D 061Ch : FMMU1_ACT
A00D 062Ch : FMMU2_ACT
A00D 063Ch : FMMU3_ACT
A00D 064Ch : FMMU4_ACT
A00D 065Ch : FMMU5_ACT
A00D 066Ch : FMMU6_ACT
A00D 067Ch : FMMU7_ACT

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ACTIVATE
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	ACTIVATE	FMMU Enable/Disable	Enables or disables FMMU. 0: Disabled 1: Enabled	R	R/W
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

30.16 SyncManager Registers

30.16.1 SyncManager Physical Start Address m Register (SMm_P_START_ADR)

This register is used to set the physical start address for the area assigned to SyncManager.

Address(es): A00D 0800h : SM0_P_START_ADR
A00D 0808h : SM1_P_START_ADR
A00D 0810h : SM2_P_START_ADR
A00D 0818h : SM3_P_START_ADR
A00D 0820h : SM4_P_START_ADR
A00D 0828h : SM5_P_START_ADR
A00D 0830h : SM6_P_START_ADR
A00D 0838h : SM7_P_START_ADR

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SMSTAADDR															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	SMSTAADDR	Physical Start Address Setting	Specify the physical start address for the area assigned to SyncManager.	R	R/(W)

m = 0 to 7
This register can only be written when SyncManager is disabled (bit 0 is 0 in the SyncManager activate m register (SMm.ACT at 0806h+8h*m).

30.16.2 SyncManager Length m Register (SMm_LEN)

This register is used to set the size of the area assigned to SyncManager.

Address(es): A00D 0802h : SM0_LEN
A00D 080Ah : SM1_LEN
A00D 0812h : SM2_LEN
A00D 081Ah : SM3_LEN
A00D 0822h : SM4_LEN
A00D 082Ah : SM5_LEN
A00D 0832h : SM6_LEN
A00D 083Ah : SM7_LEN

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SMLEN															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	SMLEN	Area Size Setting	Set the number of bytes assigned to SyncManager. Set a value greater than 1. Otherwise, SyncManager is not activated.	R	R/(W)

m = 0 to 7
This register can only be written when SyncManager is disabled (bit 0 is 0 in the SyncManager activate m register (SMm.ACT at 0806h+8h*m).

30.16.3 SyncManager Control m Register (SMm_CONTROL)

This register is used to set operation of SyncManager.

Address(es): A00D 0804h : SM0_CONTROL
A00D 080Ch : SM1_CONTROL
A00D 0814h : SM2_CONTROL
A00D 081Ch : SM3_CONTROL
A00D 0824h : SM4_CONTROL
A00D 082Ch : SM5_CONTROL
A00D 0834h : SM6_CONTROL
A00D 083Ch : SM7_CONTROL

	b7	b6	b5	b4	b3	b2	b1	b0
	—	WDTRGEN	IRQPDI	IRQECAT	DIR		OPEMODE	
Value after reset:	x	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b1, b0	OPEMODE	Operating Mode Setting	Operating mode 00: Buffer mode (3 buffer mode) 10: Mailbox mode (single buffer mode) Others: Reserved	R	R/(W)
b3, b2	DIR	Transfer Direction Setting	Transfer direction 00: Read (ECAT: read access; PDI: write access) 01: Write (ECAT: write access; PDI: read access) Others: Reserved	R	R/(W)
b4	IRQECAT	ECAT Event Interrupt Setting	Enables or disables interrupts (ECAT interrupts) by the ECAT event request register (ECAT_EVENT_REQ at 0210h). 0: Disabled 1: Enabled	R	R/(W)
b5	IRQPDI	AL Event Interrupt Setting	Enables or disables interrupts (PDI interrupts) by the AL event request register (AL_EVENT_REQ at 0220h). 0: Disabled 1: Enabled	R	R/(W)
b6	WDTRGEN	Watchdog Trigger Setting	Enables or disables watchdog trigger. 0: Disabled 1: Enabled	R	R/(W)
b7	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

This register can only be written when SyncManager is disabled (bit 0 is 0 in the SyncManager activate m register (SMm.ACT at 0806h+8h*m).

30.16.4 SyncManager Status m Register (SMm_STATUS)

This register indicates the state of SyncManager.

Address(es): A00D 0805h : SM0_STATUS
A00D 080Dh : SM1_STATUS
A00D 0815h : SM2_STATUS
A00D 081Dh : SM3_STATUS
A00D 0825h : SM4_STATUS
A00D 082Dh : SM5_STATUS
A00D 0835h : SM6_STATUS
A00D 083Dh : SM7_STATUS

	b7	b6	b5	b4	b3	b2	b1	b0
	WRBUF	RDBUF	BUFFERED		MAILBOX	—	INTRD	INTWR
Value after reset:	0	0	1	1	0	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	INTWR	Write Complete Interrupt State Indication	Indicates write complete interrupt. 1: Indicates that the first byte of the buffer was read (interrupt cleared) 0: Indicates that the buffer was successfully written.	R	R
b1	INTRD	Read Complete Interrupt State Indication	Indicates read complete interrupt. 1: Indicates that the first byte of the buffer was written (interrupt cleared) 0: Indicates that the buffer was successfully read.	R	R
b2	—	Reserved	When read, the value returned is undefined.	R	R
b3	MAILBOX	Mailbox Status Indication	Indicates the mailbox status in mailbox mode. 0: Mailbox empty 1: Mailbox full This bit is not used in buffer mode.	R	R
b5, b4	BUFFERED	Buffer Status Indication	Indicates the buffer status in buffer mode (last written buffer). 00: 1st buffer 01: 2nd buffer 10: 3rd buffer 11: No buffer written This bit is not used in mailbox mode.	R	R
b6	RDBUF	Read State Indication	Indicates that the buffer is being read.	R	R
b7	WRBUF	Write State Indication	Indicates that the buffer is being written.	R	R

m = 0 to 7

30.16.5 SyncManager Activate m Register (SMm_ACT)

This register is used to set operation of SyncManager.

Address(es): A00D 0806h : SM0_ACT
A00D 080Eh : SM1_ACT
A00D 0816h : SM2_ACT
A00D 081Eh : SM3_ACT
A00D 0826h : SM4_ACT
A00D 082Eh : SM5_ACT
A00D 0836h : SM6_ACT
A00D 083Eh : SM7_ACT

	b7	b6	b5	b4	b3	b2	b1	b0
	LATCH PDI	LATCH ECAT	—	—	—	—	REPEA TREQ	SMEN
Value after reset:	0	0	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	SMEN	SyncManager Enable/ Disable	Enables or disables SyncManager. 0: Disabled. Memory is accessed without SyncManager control. 1: Enabled. SyncManager is active and controls memory area set in configuration.	R (ack)	R/W
b1	REPEATREQ	Repeat Request	Repeat request Toggling of the repeat request signal means that retrying the mailbox is required (primarily used in conjunction with reading of the ECAT mailbox).	R (ack)	R/W
b5 to b2	—	Reserved	When read, the value returned is undefined.	R (ack)	R
b6	LATCHECAT	ECAT Latch Event Specification	ECAT latch event 0: No 1: Generates latch events if the EtherCAT master switches the buffers.	R (ack)	R/W
b7	LATCHPDI	PDI Latch Event Specification	PDI latch event 0: No 1: Generates latch events if the PDI switches the buffers or accesses the buffer start address.	R (ack)	R/W

m = 0 to 7
Reading this register from the PDI in all SyncManagers which have changed activation clears bit 4 of the AL event request register (AL_EVENT_REQ at 0220h).

30.16.6 SyncManager PDI Control m Register (SMm_PDI_CONT)

This register is used to set operation of SyncManager from the PDI.

Address(es): A00D 0807h : SM0_PDI_CONT
A00D 080Fh : SM1_PDI_CONT
A00D 0817h : SM2_PDI_CONT
A00D 081Fh : SM3_PDI_CONT
A00D 0827h : SM4_PDI_CONT
A00D 082Fh : SM5_PDI_CONT
A00D 0837h : SM6_PDI_CONT
A00D 083Fh : SM7_PDI_CONT

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	REPEATACK	DEACTIVE
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	DEACTIVE	SyncManager Operation Indication/Setting	Deactivates SyncManager. Read: 0: Normal operation. SyncManager is activated. 1: SyncManager is deactivated and reset. SyncManager locks access to memory area. Write: 0: Activates SyncManager. 1: Deactivates SyncManager. Note: Writing 1 is delayed until the end of a frame which is currently processed.	R/W	R
b1	REPEATACK	Repeat Acknowledge	Repeat Acknowledge If this bit is set to the same value as set by bit 0 (repeat request) of the SyncManager activate register (SMm.ACT at 0806h+8h*m), the PDI acknowledges the execution of a previous set repeat request.	R/W	R
b7 to b2	—	Reserved	When read, the value returned is undefined.	R	R

m = 0 to 7

30.17 Distributed Clock Registers

30.17.1 DC Receive Time Registers

30.17.1.1 Receive Time Port 0 Register (DC_RCV_TIME_PORT0)

Writing to this register latches the received time of frames at all ports and reading this register indicates the received time of a frame latched at port 0.

Address(es): A00D 0900h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RCVTIME0															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	RCVTIME0															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	RCVTIME0	Receive Time Indication/ Latch	Write: A write access to this register with the BWR, APWR (any address) or FPWR (configured address) command latches the local time when each port starts to receive a frame (first start bit of preamble). Read: Indicate the local time at the beginning of reception of the last frame containing a write access to this register. Note: The time stamps cannot be read in the same frame in which this register was written.	R	R/W

30.17.1.2 Receive Time Port 1 Register (DC_RCV_TIME_PORT1)

This register indicates the received time of the frame latched at port 1.

Address(es): A00D 0904h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	RCVTIME1															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	RCVTIME1	Receive Time Indication	Indicate the local time when port 1 starts to receive a frame (first start bit of preamble) containing the BWR, APWR or FPWR command to the receive time port 0 register (DC_RCV_TIME_PORT0 at 0900h).	R	R

30.17.2 DC Time Loop Control Unit Registers

30.17.2.1 System Time Register (DC_SYS_TIME)

This register indicates the local copy of the system time.

Address(es): A00D 0910h

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48

	SYSTIME															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	SYSTIME	System Time Indication	Access from the ECAT Read: Indicate the local copy of the system time when the frame passed the reference clock (i.e., including a system time delay). The time latched at the start of frame (SOF) is indicated. Write: A written value is compared with the local copy of the system time. The result is input to the time control loop unit.	R	R/W
			Access from the PDI Read: Indicate the local copy of the system time. The time latched when the first byte of this register was read is indicated.	R	R

30.17.2.2 Receive Time ECAT Processing Unit Register (DC_RCV_TIME_UNIT)

This register indicates the received time of a frame latched at EtherCAT processing unit.

Address(es): A00D 0918h

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48

	RCVTIMEEPU															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

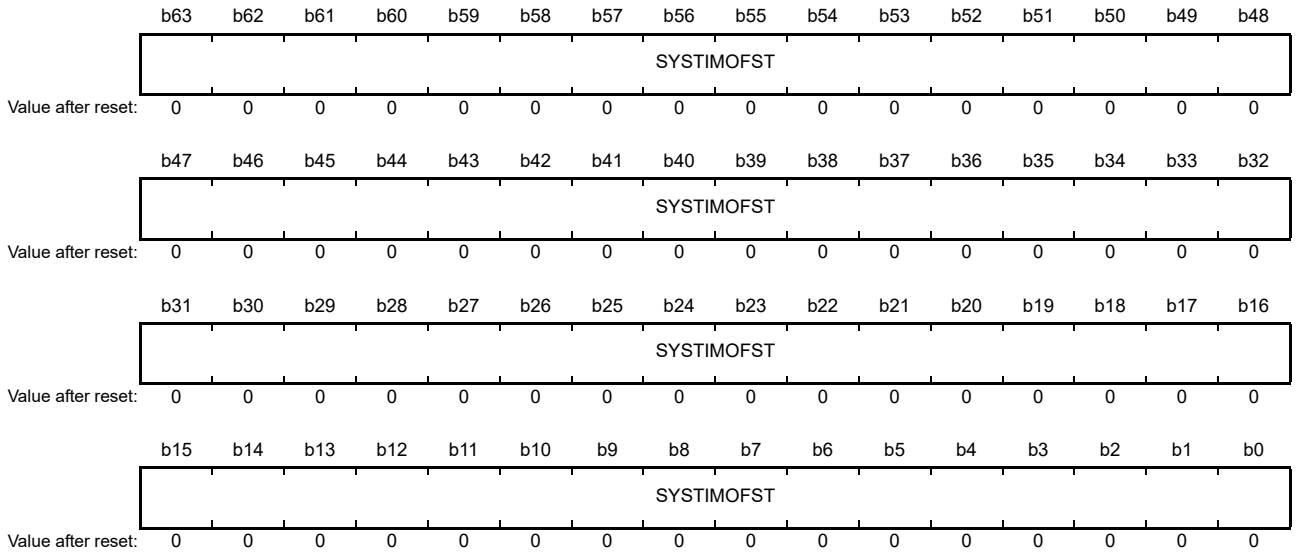
Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	RCVTIMEEPU	Receive Time Indication	This register indicates the local time at the beginning of reception by the EtherCAT processing unit of a frame (i.e. the first start bit of the preamble), including write access to the receive time port 0 register (DC_RCV_TIME_PORT0 at 0900h).	R	R

If port 0 is open, the value in this register reflects the same time as the value in the receive time port 0 register (DC_RCV_TIME_PORT0 at 0900h), but as 64 bits.

30.17.2.3 System Time Offset Register (DC_SYS_TIME_OFFSET)

This register is used to indicate a difference (offset) between the local time and system time.

Address(es): A00D 0920h

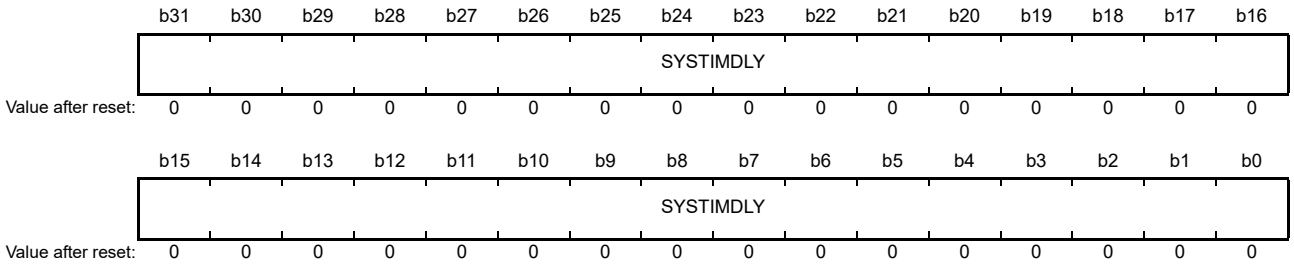


Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	SYSTIMOFST	System Time and Local Time Difference Indication	Indicate a difference between the local time and system time. This offset is added to the local time to obtain the local system time.	R	R/W

30.17.2.4 System Time Delay Register (DC_SYS_TIME_DELAY)

This register indicates a propagation delay between the reference clock and slave (ESC).

Address(es): A00D 0928h

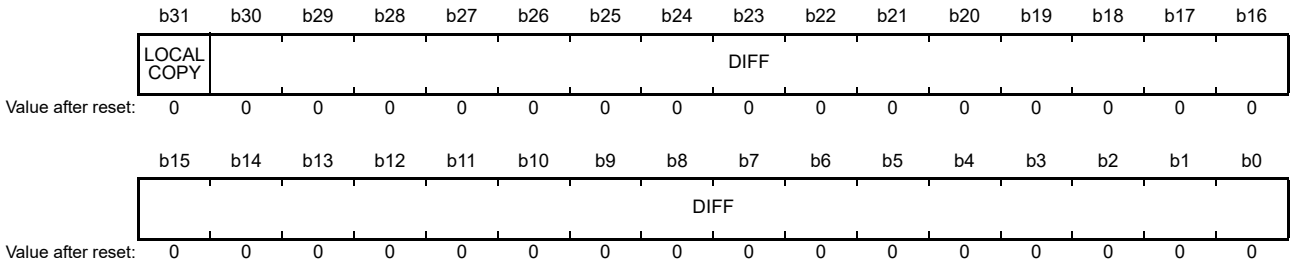


Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	SYSTIMDLY	Propagation Delay Indication	Indicate a delay between the reference clock and the ESC.	R	R/W

30.17.2.5 System Time Difference Register (DC_SYS_TIME_DIFF)

This register indicates a mean difference between the local copy of the system time and received system time.

Address(es): A00D 092Ch



Bit	Symbol	Bit Name	Description	PDI	ECAT
b30 to b0	DIFF	System Time Mean Difference Indication	Indicates a mean difference between the local copy of the system time and received system time.	R	R
b31	LOCALCOPY	System Time Greater/Less Indication	Indicates whether the local copy of the system time is greater than or equal to, or is less than, the latest received copy of the system time. 0: Local copy of the system time greater than or equal to the received system time 1: Local copy of the system time less than the received system time	R	R

30.17.2.6 Speed Counter Start Register (DC_SPEED_COUNT_START)

This register is used to set the bandwidth for drift correction of the local copy of the system time.

Address(es): A00D 0930h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPDCNTSTRT														
Value after reset:	x	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b14 to b0	SPDCNTSTRT	Drift Correction Bandwidth Setting	Indicate the bandwidth for adjustment of the local copy of the system time (larger values → smaller bandwidth and smoother adjustment). A write access resets the system time difference register (DC_SYS_TIME_DIFF at 092Ch) and the speed counter difference register (DC_SPEED_COUNT_DIFF at 0932h). Valid range: 0080h to 3FFFh	R	R/W
b15	—	Reserved	When read, the value returned is undefined. When writing to this bit, write 0.	R	R/W

30.17.2.7 Speed Counter Difference Register (DC_SPEED_COUNT_DIFF)

This register indicates the deviation between the local clock period and reference clock's clock period.

Address(es): A00D 0932h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPDCNTDIFF															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	SPDCNTDIFF	Clock Period Deviation Indication	Indicate the deviation between the local clock period and reference clock's clock period (represented by two's complements). Range: ± (speed counter start value - 7Fh)	R	R

30.17.2.8 System Time Difference Filter Depth Register (DC_SYS_TIME_DIFF_FIL_DEPTH)

This register is used to set the filter depth for averaging the received system time deviation.

Address(es): A00D 0934h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SYSTIMDEP			
Value after reset:	x	x	x	x	0	1	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b3 to b0	SYSTIMDEP	Filter Depth Setting	Set the filter depth for averaging the received system time deviation. A write access resets the system time difference register (DC_SYS_TIME_DIFF at 092Ch).	R	R/W
b7 to b4	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R	R/W

30.17.2.9 Speed Counter Filter Depth Register (DC_SPEED_COUNT_FIL_DEPTH)

This register is used to set the filter depth for averaging the clock period deviation.

Address(es): A00D 0935h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	CLKPERDEP			
Value after reset:	x	x	x	x	1	1	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b3 to b0	CLKPERDEP	Filter Depth Setting	Set the filter depth for averaging the clock period deviation. A write access resets the internal speed counter filter.	R	R/W
b7 to b4	—	Reserved	When read, the value returned is undefined. When writing to these bits, write 0.	R	R/W

30.17.3 Cyclic Unit Control Registers

30.17.3.1 Cyclic Unit Control Register (DC_CYC_CONT)

This register sets whether to control SYNC and latch units by the ECAT or PDI.

Address(es): A00D 0980h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	LATCH1	LATCH0	—	—	—	SYNCOUT
Value after reset:	x	x	0	0	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	SYNCOUT	SYNC Output Unit Control Setting	Sets control of the SYNC output unit. 0: ECAT control 1: PDI control	R	R/W
b3 to b1	—	Reserved	When read, the value returned is undefined.	R	R
b4	LATCH0	Latch Input Unit 0 Control Setting	Sets control of latch input unit 0. 0: ECAT control 1: PDI control Note: Latch interrupt is routed to the ECAT or PDI in accord with this setting.	R	R/W
b5	LATCH1	Latch Input Unit 1 Control Setting	Sets control of latch input unit 1. 0: ECAT control 1: PDI control Note: Latch interrupt is routed to the ECAT or PDI in accord with this setting.	R	R/W
b7, b6	—	Reserved	When read, the value returned is undefined.	R	R

30.17.4 SYNC Output Unit Registers

30.17.4.1 Activation Register (DC_ACT)

This register is used to activate the Sync output unit.

Address(es): A00D 0981h

	b7	b6	b5	b4	b3	b2	b1	b0
	DBGPULSE	NEARFUTURE	STARTTIME	EXTSTARTTIME	AUTOACT	SYNC1	SYNC0	SYNCACT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	SYNCACT	Sync Output Unit Activation	Activates the Sync output unit. 0: Deactivated 1: Activated Note: Write 1 after the start time was written.	R/(W)	R/(W)
b1	SYNC0	SYNC0 Output Setting	Sets SYNC0 output. 0: Deactivated 1: SYNC0 pulse output is generated.	R/(W)	R/(W)
b2	SYNC1	SYNC1 Output Setting	Sets SYNC1 output. 0: Deactivated 1: SYNC1 pulse output is generated.	R/(W)	R/(W)
b3	AUTOACT	SYNC Output Unit Activation	Sets whether to activate the Sync output unit automatically by writing to the start time cyclic operation register (DC_CYC_START_TIME at 0990h): 0: Deactivated 1: Activated. Bit 0 is automatically set to 1 in this register after the start time is written.	R/(W)	R/(W)
b4	EXTSTARTTIME	Start Time Cyclic Operation Extension	Extends start time cyclic operation. 0: No extension 1: Extends the start time written with 32 bits to 64 bits	R/(W)	R/(W)
b5	STARTTIME	Start Time Plausibility	Selects whether checking the plausibility of the start time and response to implausible start times is to proceed. 0: Disabled. Sync signal is generated if the start time is reached. 1: Sync signal is generated immediately if the start time is outside the range of the near future.	R/(W)	R/(W)
b6	NEARFUTURE	Near Future Range Setting	Sets the range to be considered the near future. 0: Up to 2^{63} ns from now (1/2 of the DC width) 1: Up to 2^{31} ns from now (about 2.1 s)	R/(W)	R/(W)
b7	DBGPULSE	Debug Pulse Setting	Sets Sync signal debug pulse. 0: Deactivated 1: Immediately generates a single debug ping on the SYNC0 and SYNC1 pins in accord with the setting of bits 2 and 1 of this register. This bit is self-cleared and always read as 0.	R/(W)	R/(W)

Writing to this register depends on the setting of bit 0 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.4.2 SYNC Signal Pulse Length Register (DC_PULSE_LEN)

This register indicates the pulse length of SYNC signals.

Address(es): A00D 0982h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PULSELEN															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b15 to b0	PULSELEN	SYNC Signal Pulse Length Indication	Indicate the pulse length of SYNC signals (in units of 10 ns) 0: Acknowledge mode. In this mode, SYNC signal is cleared by reading the SYNC0 or SYNC1 status register (DC_SYNC0/1_STAT at 098Eh, 098Fh).	R	R

30.17.4.3 Activation Status Register (DC_ACT_STAT)

This register indicates the activation status of SYNC output signals.

Address(es): A00D 0984h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	START TIME	SYNC1 ACT	SYNC0 ACT
Value after reset:	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	SYNC0ACT	SYNC0 Status Indication	Indicates the activation state of SYNC0. 0: First SYNC0 pulse is not pending. 1: First SYNC0 pulse is pending.	R	R
b1	SYNC1ACT	SYNC1 Status Indication	Indicates the activation state of SYNC1. 0: First SYNC1 pulse is not pending. 1: First SYNC1 pulse is pending.	R	R
b2	STARTTIME	Plausibility Result Indication	Indicates the plausibility check result of the start time cyclic operation register (DC_CYC_START_TIME at 0990h) while the Sync output unit is activated. 0: The start time was within the near future. 1: The start time was out of the near future.	R	R
b7 to b3	—	Reserved	When read, the value returned is undefined.	R	R

30.17.4.4 SYNC0 Status Register (DC_SYNC0_STAT)

This register indicates the state of SYNC0 output. It is only used in acknowledge mode.

Address(es): A00D 098Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SYNC0 STA
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	SYNC0STA	SYNC0 State Indication	Indicates the SYNC0 state for acknowledge mode. SYNC0 in acknowledge mode is cleared by reading this register from the PDI. This bit is only used in acknowledge mode.	R (ack)	R
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

30.17.4.5 SYNC1 Status Register (DC_SYNC1_STAT)

This register indicates the state of SYNC1 output. It is only used in acknowledge mode.

Address(es): A00D 098Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SYNC1 STA
Value after reset:	x	x	x	x	x	x	x	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	SYNC1STA	SYNC1 State Indication	Indicates the SYNC1 state for acknowledge mode. SYNC1 in acknowledge mode is cleared by reading this register from the PDI. This bit is only used in acknowledge mode.	R (ack)	R
b7 to b1	—	Reserved	When read, the value returned is undefined.	R	R

30.17.4.6 Start Time Cyclic Operation/Next SYNC0 Pulse Register (DC_CYC_START_TIME)

Writing to this register sets the start time of cyclic operation. Reading this register indicates the system time of the next SYNC0 pulse.

Address(es): A00D 0990h

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48
	STATIM															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b47	b46	b45	b44	b43	b42	b41	b40	b39	b38	b37	b36	b35	b34	b33	b32
	STATIM															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	STATIM															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	STATIM															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	STATIM	Start Time Setting/ System Time Indication	Write: Set the start time (in the system time) of cyclic operation in ns units. Read: Indicate the system time of the next SYNC0 pulse in ns units.	R/(W)	R/(W)

Writing to this register depends on the setting of bit 0 of the cyclic unit control register (DC_CYC_CONT at 0980h). Only writable when bit 0 is 0 in the SYNC activation register (DC_ACT at 0981h).
When auto-activation is enabled, upper 32 bits are automatically extended if only lower 32 bits are written within one frame.

30.17.4.7 Next SYNC1 Pulse Register (DC_NEXT_SYNC1_PULSE)

This register indicates the system time of the next SYNC1 pulse.

Address(es): A00D 0998h

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48

	SYNC1PULSE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	SYNC1PULSE	SYNC1 Pulse System Time Indication	Indicate the system time of the next SYNC1 pulse in ns units.	R	R

30.17.4.8 SYNC0 Cycle Time Register (DC_SYNC0_CYC_TIME)

This register is used to set the time between consecutive SYNC0 pulses.

Address(es): A00D 09A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SYNC0CYC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SYNC0CYC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	SYNC0CYC	Time Between Consecutive SYNC0 Pulses	Set the time between two consecutive SYNC0 pulses in ns units. 0: Single shot mode. Only one SYNC0 pulse is generated in single shot mode.	R/(W)	R/(W)

Writing to this register depends on the setting of bit 0 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.4.9 SYNC1 Cycle Time Register (DC_SYNC1_CYC_TIME)

This register is used to set the time between SYNC1 and SYNC0 pulses.

Address(es): A00D 09A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SYNC1CYC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SYNC1CYC															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	SYNC1CYC	Time between SYNC1 and SYNC0 Pulses	Set the time between SYNC1 and SYNC0 pulses in ns units.	R/(W)	R/(W)

Writing to this register depends on the setting of bit 0 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.5 Latch Input Unit Registers

30.17.5.1 Latch 0 Control Register (DC_LATCH0_CONT)

This register is used to control the edge function of the latch 0 input signal.

Address(es): A00D 09A8h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	NEGEDGE	POSEDGE
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	POSEDGE	Latch 0 Positive Edge Function Setting	Sets the function of the rising edge of the latch 0 input signal. 0: Continuous latch active 1: Single event (only first event active)	R/(W)	R/(W)
b1	NEGEDGE	Latch 0 Negative Edge Function Setting	Sets the function of the falling edge of the latch 0 input signal. 0: Continuous latch active 1: Single event (only first event active)	R/(W)	R/(W)
b7 to b2	—	Reserved	When read, the value returned is undefined.	R/(W)	R

Writing to this register depends on the setting of bit 4 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.5.2 Latch 1 Control Register (DC_LATCH1_CONT)

This register is used to control the edge function of the latch 1 input signal.

Address(es): A00D 09A9h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	NEGEDGE	POSEDGE
Value after reset:	x	x	x	x	x	x	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	POSEDGE	Latch 1 Positive Edge Function Setting	Sets the function of the rising edge of the latch 1 input signal. 0: Continuous latch active 1: Single event (only first event active)	R/(W)	R/(W)
b1	NEGEDGE	Latch 1 Negative Edge Function Setting	Sets the function of the falling edge of the latch 1 input signal. 0: Continuous Latch active 1: Single event (only first event active)	R/(W)	R/(W)
b7 to b2	—	Reserved	When read, the value returned is undefined.	R/(W)	R

Writing to this register depends on the setting of bit 5 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.5.3 Latch 0 Status Register (DC_LATCH0_STAT)

This register indicates the state of the latch 0 input signal.

Address(es): A00D 09AEh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PINSTATE	EVENTNEG	EVENTPOS
Value after reset:	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	EVENTPOS	Latch 0 Positive Edge Event Indication	Indicates detection of rising edges of the event latch 0 signal. 0: Rising edge not detected or continuous mode 1: Rising edge detected and mode is single-event. This flag is cleared by reading the latch 0 time positive edge register (DC_LATCH0_TIME_POS at 09B0h).	R	R
b1	EVENTNEG	Latch 0 Negative Edge Event Indication	Indicates detection of falling edges of the event latch 0 signal. 0: Falling edge not detected or continuous mode 1: Falling edge detected and mode is single-event. This flag is cleared by reading the latch 0 time negative edge register (DC_LATCH0_TIME_NEG at 09B8h).	R	R
b2	PINSTATE	Latch 0 Input Pin State Indication	Indicates the state of the latch 0 input pin.	R	R
b7 to b3	—	Reserved	When read, the value returned is undefined.	R	R

30.17.5.4 Latch 1 Status Register (DC_LATCH1_STAT)

This register indicates the state of the latch 1 input signal.

Address(es): A00D 09AFh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	PINSTATE	EVENTNEG	EVENTPOS
Value after reset:	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b0	EVENTPOS	Latch 1 Positive Edge Event Indication	Indicates detection of rising edges of the event latch 1 signal. 0: Rising edge not detected or continuous mode 1: Rising edge detected and mode is single-event. This flag is cleared by reading the latch 1 time positive edge register (DC_LATCH1_TIME_POS at 09C0h).	R	R
b1	EVENTNEG	Latch 1 Negative Edge Event Indication	Indicates detection of falling edges of the event latch 1 signal. 0: Falling edge not detected or continuous mode 1: Falling edge detected and mode is single-event. This flag is cleared by reading the latch 1 time negative edge register (DC_LATCH1_TIME_NEG at 09C8h).	R	R
b2	PINSTATE	Latch 1 Input Pin State Indication	Indicates the state of the latch 1 input pin.	R	R
b7 to b3	—	Reserved	When read, the value returned is undefined.	R	R

30.17.5.5 Latch 0 Time Positive Edge Register (DC_LATCH0_TIME_POS)

This register indicates the system time at the rising edge of the latch 0 input signal.

Address(es): A00D 09B0h

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48

	SYSTIME															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	SYSTIME	System Time Indication	Indicate the system time captured at the rising edge of the latch 0 input signal. Reading this register clears bit 0 of the latch 0 status register (DC_LATCH0_STAT at 09AEh).	R (ack)	R (ack)

Bits 63 to 8 are internally latched (ECAT/PDI independently) when bits 7 to 0 are read, which guarantees reading a consistent value.

Clearing the latch 0 status flag function depends on the setting of bit 4 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.5.6 Latch 0 Time Negative Edge Register (DC_LATCH0_TIME_NEG)

This register indicates the system time at the falling edge of the latch 0 input signal.

Address(es): A00D 09B8h

	SYSTIME															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	SYSTIME	System Time Indication	Indicate the system time captured at the falling edge of the latch 1 input signal. Reading this register clears bit 1 of the latch 1 status register (DC_LATCH1_STAT at 09AFh).	R (ack)	R (ack)

Bits 63 to 8 are internally latched (ECAT/PDI independently) when bits 7 to 0 are read, which guarantees reading a consistent value.

Clearing the latch 1 status flag function depends on the setting of bit 5 of the cyclic unit control register (DC_CYC_CONT at 0980h).

30.17.6 SyncManager Event Time Registers

30.17.6.1 Buffer Change Event Time Register (DC_ECAT_CNG_EV_TIME)

This register indicates the local time at the beginning of a frame which causes SyncManager to generate an ECAT event (switching the buffers).

Address(es): A00D 09F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ECATCHANGE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ECATCHANGE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	ECATCHANGE	Local Time Indication	Indicate the local time at the beginning of a frame which causes at least one SyncManager to generate an ECAT event (switching the buffers).	R	R

Bits 31 to 8 are internally latched (ECAT/PDI independently) when bits 7 to 0 are read, which guarantees reading a consistent value.

30.17.6.2 PDI Buffer Start Event Time Register (DC_PDI_START_EV_TIME)

This register indicates the local time when SyncManager has generated a PDI event (access to the address where a buffer starts).

Address(es): A00D 09F8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PDISTART															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PDISTART															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	PDISTART	Local Time Indication	Indicate the local time when at least one SyncManager has generated a PDI event (access to the address where a buffer starts).	R	R

Bits 31 to 8 are internally latched (ECAT/PDI independently) when bits 7 to 0 are read, which guarantees reading a consistent value.

30.17.6.3 PDI Buffer Change Event Time Register (DC_PDI_CNG_EV_TIME)

This register indicates the local time when SyncManager has generated a PDI event (switching the buffers).

Address(es): A00D 09FCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PDICHANGE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PDICHANGE															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	PDICHANGE	Local Time Indication	Indicate the local time when at least one SyncManager has generated a PDI event (switching the buffers).	R	R

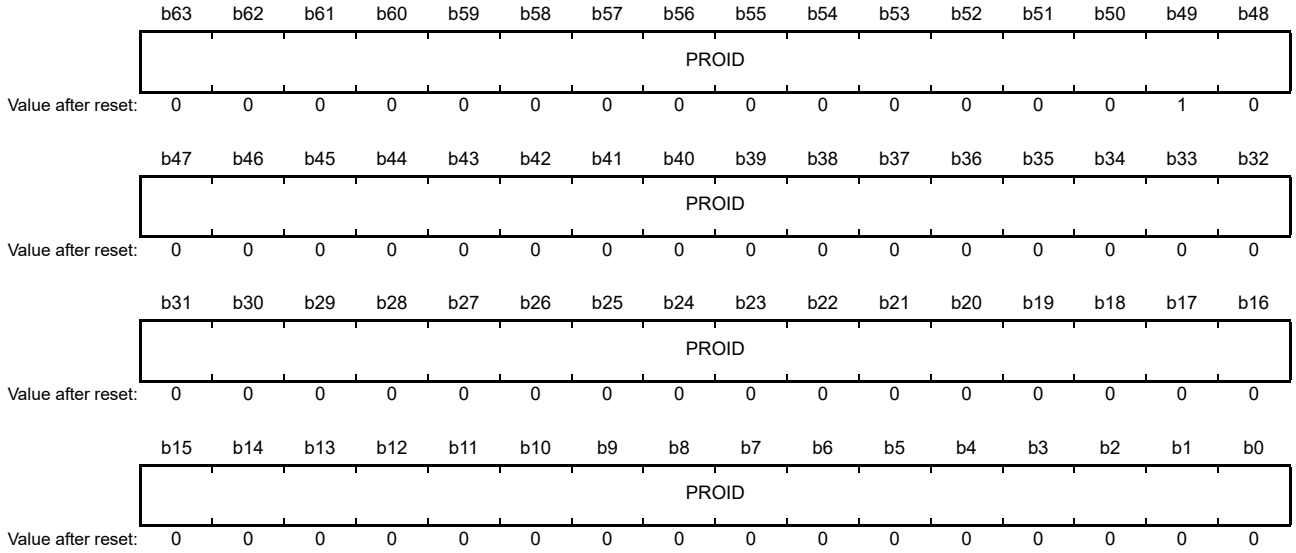
Bits 31 to 8 are internally latched (ECAT/PDI independently) when bits 7 to 0 are read, which guarantees reading a consistent value.

30.18 Other Registers

30.18.1 Product ID Register (PRODUCT_ID)

This register indicates the product ID.

Address(es): A00D 0E00h



Bit	Symbol	Bit Name	Description	PDI	ECAT
b63 to b0	PROID	Product ID Indication	Product ID	R	R

30.18.2 Vendor ID Register (VENDOR_ID)

This register indicates the vendor ID.

Address(es): A00D 0E08h

	b63	b62	b61	b60	b59	b58	b57	b56	b55	b54	b53	b52	b51	b50	b49	b48
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b47	b46	b45	b44	b43	b42	b41	b40	b39	b38	b37	b36	b35	b34	b33	b32
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	VENDORID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VENDORID															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	PDI	ECAT
b31 to b0	VENDORID	Vendor ID Indication	Vendor ID	R	R
b63 to b32	—	Reserved	When read, the value returned is undefined.	R	R

30.18.3 User RAM (USER_RAM)

This area of RAM indicates the supported features dependent on the IP core configuration, and takes up the 128 bits from A00D 0F80h to A00D 0FFFh. An initial value of 1 means that the implementation of this module supports the corresponding feature, except in the case of bits 7 to 0, which indicate the number of bits defined in the user RAM and the initial value is 33h for this module.

Bit Position	Description	Initial Value
7 to 0	Number of bits for defining extended functionality. The value is 51 (33h) for this module.	33h
8	Extended DL control register (0102h, 0103h)	1
9	AL status code register (0134h, 0135h)	1
10	ECAT event mask (0200h, 0201h)	1
11	Configured station alias (0012h, 0013h)	1
12	General input (0F18h, 0F1Fh)	0
13	General output (0F10h, 0F17h)	0
14	AL event mask (0204h, 0207h)	1
15	Physical read/write offset (0108h, 0109h)	1
16	Watchdog divider writable (0400h, 0401h) and watchdog PDI (0410h, 0f11h)	1
17	Watchdog counter (0442h, 0443h)	1
18	Write protection (0020h, 0031h)	1
19	Reset (0040h, 0041h)	1
20	Reserved	0
21	DC SyncManager event time (09F0h, 09FFh)	1
22	ECAT processing unit/PDI error counter (030Ch, 030Dh)	1
23	EEPROM size configurable (Bit 7 at 0502h) 0: EEPROM size fixed up to 16 Kbits 1: EEPROM Size configurable	1
26 to 24	Reserved	0
27	Lost link counter (0310h, 0313h)	1
28	MII management interface (0510h, 0515h)	1
29	Enhanced link detection MII	1
30	Enhanced link detection EBUS	0
31	Run LED	1
32	Link/activity LED	1
33	Reserved	0
35 to 34	Reserved	1
36	Reserved	0
37	Reserved	1
38	DC Time loop control assigned to PDI	0
39	Link detection and configuration by MI	0
40	MI control by PDI	1
41	Automatic TX shift	1
42	EEPROM emulation	0
49 to 43	Reserved	0
50	ERR LED, RUN/ERR LED override	1
Others	Reserved	Reserved

30.18.4 Process Data RAM (DATA_RAM)

The process data RAM is used for process data and mailbox, and takes up 8 Kbytes from A00D 1000h to A00D 2FFFh. This RAM is only accessible when the EEPROM is correctly loaded (i.e., when bit 0 is 1 in the ESC DL status register, ESC_DL_STATUS, at 0110h).

30.18.5 Setting the Module-Stop Function

EtherCAT modules are stopped in the initial state. If the modules are to be used, set the MSTPCRB.MSTPCRB15 bit for release from the module-stop state. Note that re-setting the module-stop state is prohibited following release from the module-stop state. Operation of the modules if they are stopped following release and then released again is not guaranteed. Release from the module-stop state can proceed again after the modules have been returned to their initial states (stopped) by a reset.

30.19 Initial Settings

To initialize the EtherCAT, follow the procedure below.

- Set the offset address of the PHY module in the CATOFFADD register.
- Set the size of the EEPROM in the CATEMMD register.
- Set the delay time of the TXC pin in the CATTXCSFT register.
- Release the EtherCAT from the module stop state by using the MSTPCRB15 bit in the MSTPCRB register.
- Release the ESC and PHY modules from the reset state by using the CATRST and PHYRST bits in the ETHSFTRST register.

On release from the reset state, the ESC will automatically load the EEPROM data and be activated.

30.20 Configuration of the Reset Circuit

Figure 30.2 shows the configuration of the reset circuit of the ESC. On reception of a reset request (0040h) from the ECAT or a reset request (0041h) from the PDI, the ESC stops and the output of the reset signal from the ESC becomes high. The output of this reset signal from the ESC drives the signal on the PHYRESETOUT# pin to the low level and the externally connected Ethernet PHY chip is reset. An ETHCRSTI interrupt is generated at the same time.

To release the ESC from the reset state, the CATRST bit in the ETHSFTRST register must be switched from 1 to 0 then back to 1. Note that the output of the reset signal from the ESC becomes low when the input of the reset signal to the ESC changes from high to low. Restarting of the ESC begins when the input of the reset signal to the ESC changes from low to high and loading of the EEPROM starts. Loading of the EEPROM is completed in about 1 ms. The timing with which the Ethernet PHY chip is released from the reset state must be set so that it will only recommence operations after the ESC has started. Figure 30.3 shows the timing chart.

Resetting the ESC by using the CATRST bit of the ETHSFTRST register instead of by the ECAT or PDI issuing a reset request (0040h or 0041h) is also possible. In this case, the PHYRESETOUT# pin does not automatically go to the low level, so use the PHYRST bit of the ETHSFTRST register to place the Ethernet PHY chip in the reset state beforehand. Figure 30.4 shows the timing chart.

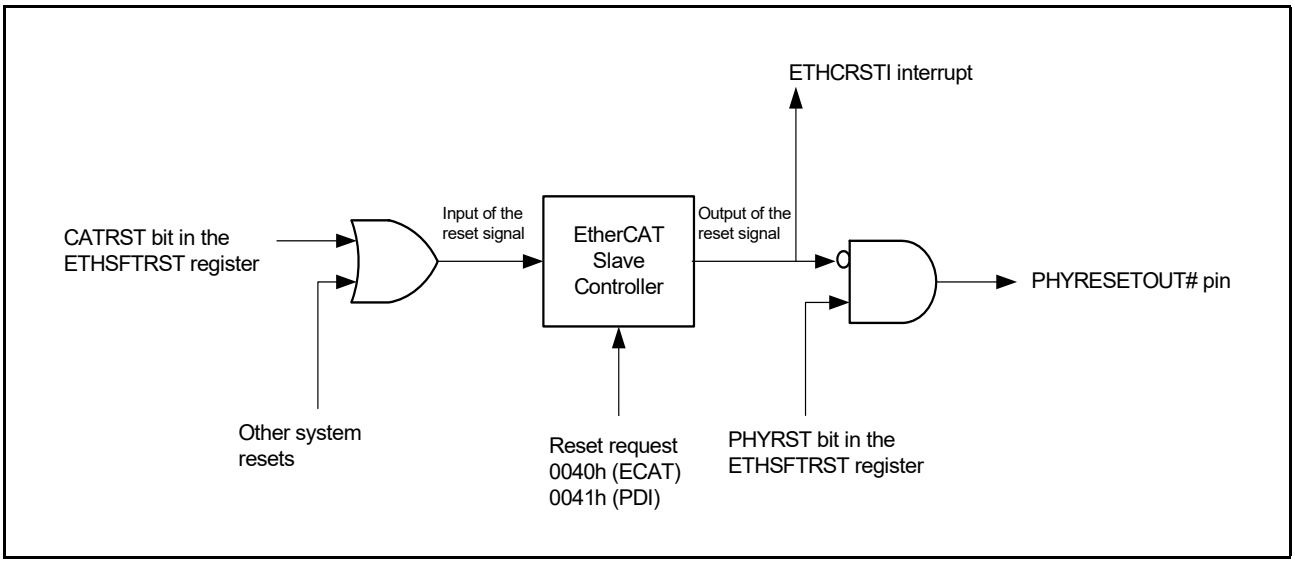


Figure 30.2 Configuration of the Reset Circuit of the EtherCAT Slave Controller

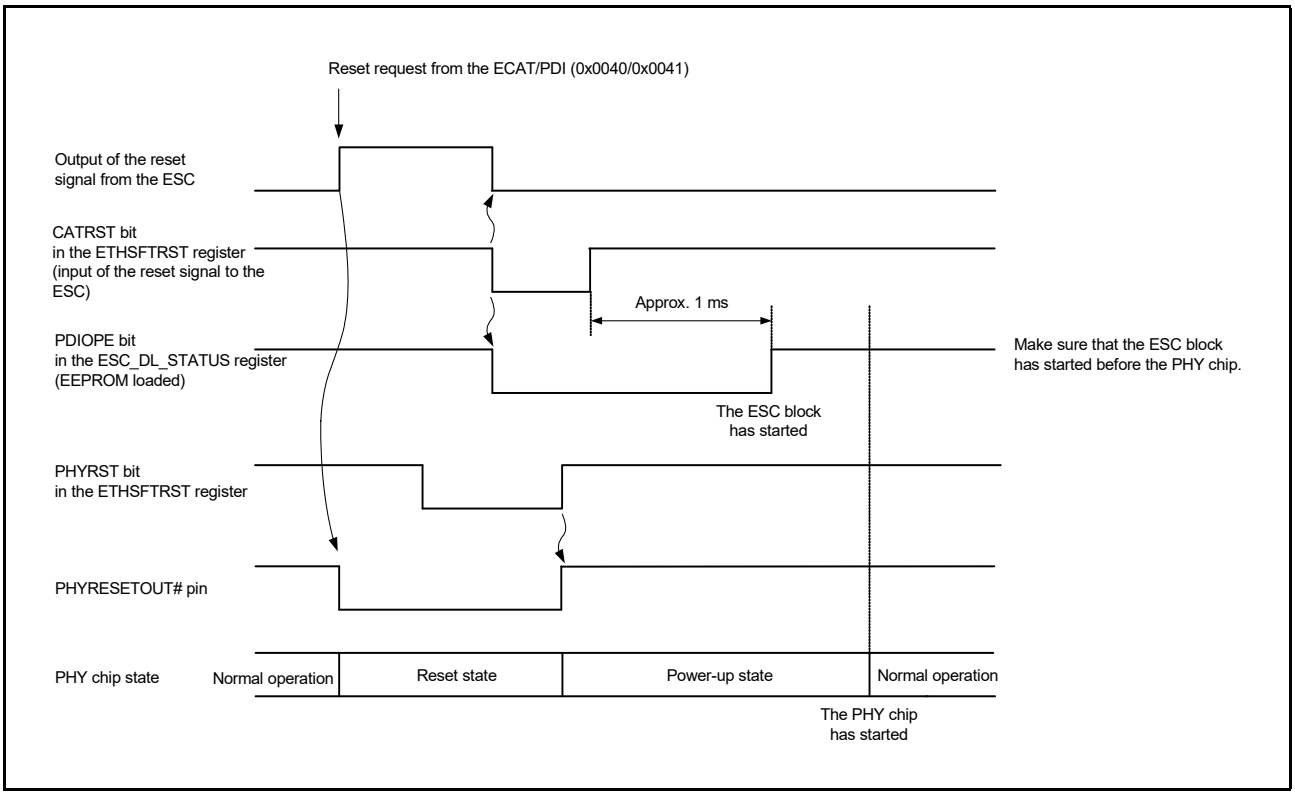

Figure 30.3 Timing with which the EtherCAT Slave Controller is Reset (in the Case of a Reset Requested by the ECAT or PDI)

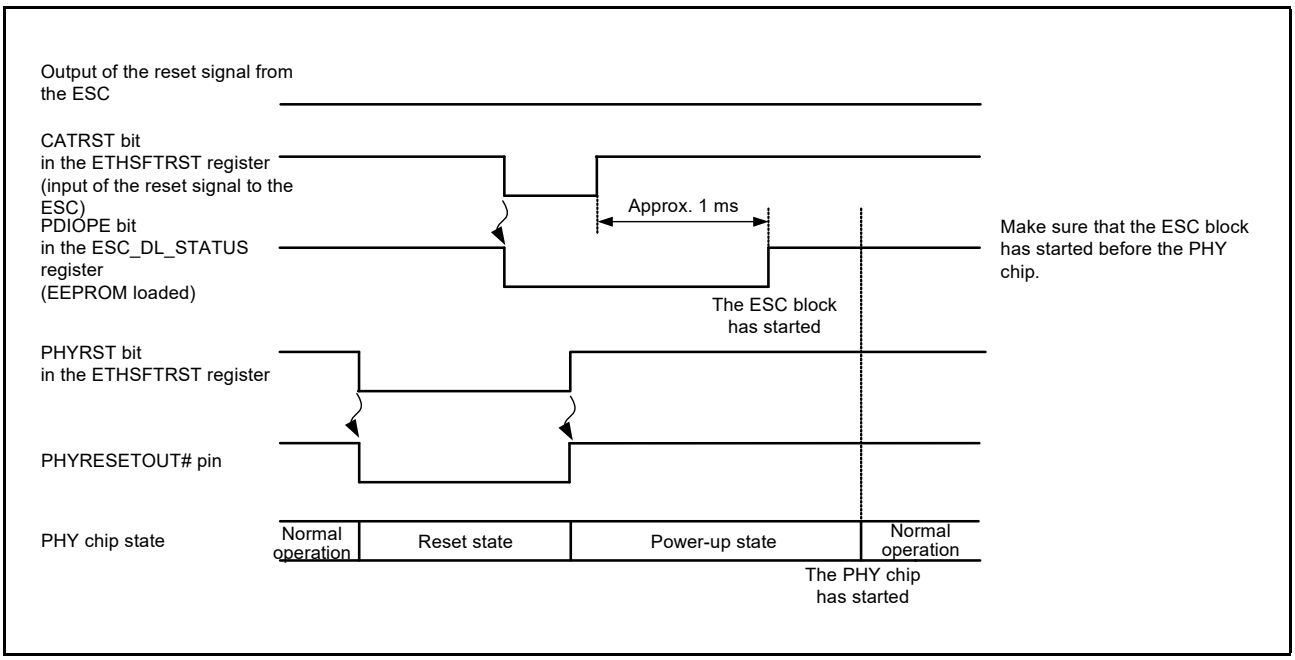

Figure 30.4 Timing with which the EtherCAT Slave Controller is Reset (in the Case of the CATRST Bit of the ETHSFTRST Register being Used to Reset the ESC)

31. USB2.0HS Host Module (USBh)

31.1 Overview

The USB module of this LSI is a dual-role device that has USB 2.0 host and function modules. However, it does not have a facility for detecting the ID and so does not support On-the-Go (OTG) functionality.
This LSI handles a single USB port for either host controller or function controller operation. The port connection path select input signal bits (PHYSET1.P1PORTSEL[1:0]) are used to switch between host controller and function controller operation.
Since operation as a host controller or a function controller are exclusive of each other, dynamic switching between the types of operation is not possible.

This section describes host controller operation.

USB2.0 Host Controller Operation

- Conforms to Universal Serial Bus Specification Revision 2.0.
- Conforms to Open Host Controller Interface (OHCI) Specification for USB Rev 1.0a.
- Conforms to Enhanced Host Controller Interface (EHCI) Specification for USB Rev 1.0.
- Supports USB2.0 high-speed (480 Mbps) and full-speed (12 Mbps) transfer.

Note: Low-speed (1.5 Mbps) is not supported.

- Supports the USB2.0 compliance test function.

Figure 31.1 is a block diagram of the USB module.

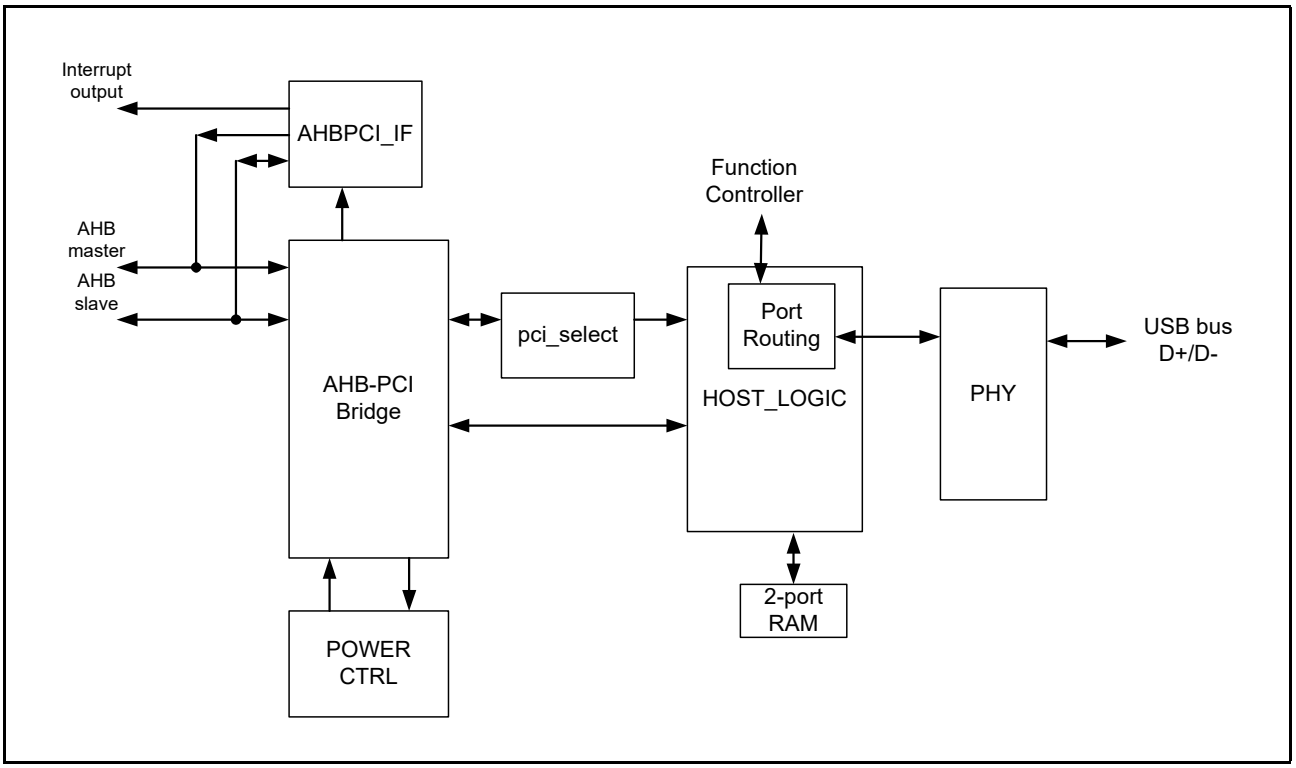

Figure 31.1 Block Diagram of the USB Module

(1) Host Logic

A USB 2.0 logic conforming to the EHCI and OHCI standards. It has control circuits such as a list processing circuit, a serial-parallel circuit, a USB buffer, and executes high-speed, and full-speed USB transfer.

(2) UTMI+ Transceiver

A USB 2.0 UTMI transceiver with an interface conforming to the UTMI+ standard.

(3) AHB-PCI Bridge

A module for conversion between AHB bus cycles and PCI bus cycles to the hot logic. Access from the CPU to registers in the bridge or host logic is performed through the slave interface in the bridge. Access by the host logic with the PCI as the master is transferred to the AHB bus through the master interface in the bridge.

31.1.1 Precautions on Use of USB Host Controller

The following describes precautions on use of the USB host controller.

31.1.1.1 General Precautions

(1) Dynamic changes in PCLKA, USBPCLK, and USBMCLK are not supported except for the clock stop state.
(2) When using isochronous transfer, evaluate performance at the application level to confirm that the expected performance is obtained.
(3) The USB host controller outputs the logical OR of four internal interrupt signals. See section 31.6, Interrupts.
(4) It may take a long time to actually clear an interrupt after a register is accessed to clear the interrupt. For the actionnecessary during this wait time, see section 31.6.3, Time Required to Clear Interrupt Signals.

31.1.1.2 AHB Interface

(1) Only 32-bit access is available for AHB slave access to the USB host controller; 8- or 16-bit access is not allowed.
(2) When using the wait mode with HRESP = RETRY, access the following mode switch register in the AHB bridge first.
- Bit 17 (SMODE_READY_CTR) in the AHB_BUS_CTR register
(3) The read or written data is not guaranteed for register access while the clock is stopped.

31.1.1.3 Operating Procedures

(1) See the operating procedures described in the following sections.
- Initial settings: section 31.8, Operating Procedures
- Mapping in the AHB space and PCI space: section 31.4.1, Register Access.

31.2 Register Mapping

31.2.1 Register Mapping

The register space is broadly divided into the following three areas.

1. OHCI/EHCI operational register area
2. PCI configuration space area
3. AHB-PCI bridge PCI communication area

To access each PICI configuration space, the AHPBPCI_WIN1_CTR register in the AHB-PCI bridge register area should be used. In addition to register mapping in the AHB space, the addresses of the OHCI/EHCI operational registers and PCI communication spaces should be correctly mapped to the PCI space in the USB host controller. For details of access and address mapping of each register, see section 31.4.1, Register Access.
The range of address input is from A004 0000h to A005 FFFFh. Do not access the reserved area (A005 0C00h to A005 FFFFh).

31.3 Register Descriptions

This section describes details of the register functions.

31.3.1 OHCI Operational Registers

Access the OHCI operational registers after starting up the PHY internal PLL. For details, see Figure 31.13, Initial Setting Sequence.

31.3.1.1 HcRevision Register

Address(es) A004 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	Revision[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Revision[7:0]	HCI revision	These bits indicate the version of the HCI specifications implemented in the host logic. As the host logic conforms to OHCI standard 1.0a, this value is set to 10h.	R
b31 to b8	—	Reserved	Don't care	R

31.3.1.2 HcControl Register

Address(es) A004 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	RWE	RWC	—	HCFS[1:0]		BLE	CLE	IE	PLE	CBSR[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CBSR[1:0] (ControlBulk ServiceRatio)	Control / bulk transfer service ratio specifying	These bits specify the service ratio of control transfer to bulk transfer. In periodic list processing, the service ratio specified in these bits is kept during transfer. **CBSR** / **Service Ratio of Bulk ED : Control ED** 00 1:1 01 2:1 10 3:1 11 4:1	R/W
b2	PLE (PeriodicList Enable)	Periodic list setting	This bit specifies whether to perform periodic list processing. The setting of this bit takes effect from the next frame. 0: Periodic list processing is not done. 1: Period list processing is done.	R/W
b3	IE (Isochronous Enable)	Isochronous ED processing setting	This bit specifies whether to perform isochronous ED processing. The setting of this bit takes effect from the next frame. When an isochronous ED is found during list processing, the host logic checks this bit to determine whether to perform isochronous ED processing. 0: Isochronous transfer processing is not done. 1: Isochronous transfer processing is done.	R/W
b4	CLE (ControlListEnable)	Control list processing setting	This bit specifies whether to perform control list processing. The setting of this bit takes effect from the next frame. The control list can be modified only when this value is 0. 0: Control list processing is not done. 1: Control list processing is done.	R/W
b5	BLE (BulkListEnable)	Bulk list processing setting	This bit specifies whether to perform bulk list processing. The setting of this bit takes effect from the next frame. The bulk list can be modified only when this value is 0. 0: Bulk list processing is not done. 1: Bulk list processing is done.	R/W
b7, b6	HCFS[1:0] (Host Controller FunctionalState)	Host logic operation status	These bits indicate the operating state of the host logic. Upon entering the USB operational state, the host logic starts management of frames delimited at 1-ms intervals. The operating state is always controlled by software except for transition to the USB resume state due to remote wakeup in the USB suspend state. These bits indicate the USB reset state after a hard ware reset. After a software reset, the state shifts to the USB suspend state. b7 b6 0 0: USB Reset 0 1: USB Resume 1 0: USB Operational 1 1: USB Suspend	R/W

Bit	Symbol	Bit Name	Description	R/W
b8	—	Reserved	When writing, write 0.	R/W
b9	RWC (RemoteWakeUpConnect)	Remote WakeUp support setting	This bit indicates whether the host logic supports remote wakeup. To support remote wakeup by the system, set this bit during initialization. 0: Remote WakeUp is not supported. 1: Remote WakeUp is supported.	R/W
b10	RWE (RemoteWakeUpEnable)	PME assertion control	This bit controls PME assertion. When this bit is 1, PME is asserted when bit 3 (RD) in the HcInterruptStatus register is set to 1. 0: PME is not asserted when Resume is detected (PME is disabled). 1: PME is asserted when Resume is detected (PME is enabled).	R/W
b31 to b11	—	Reserved	When writing, write 0.	R/W

31.3.1.3 HcCommandStatus Register

Address(es) A004 0008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SOC[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	OCR	BLF	CLF	HCR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	HCR (HostController Reset)	Host logic software reset start	This bit starts software reset of the host logic. When this bit is set, the USB suspend state is entered regardless of the functional state of the host logic.	W
b1	CLF (ControlList Filled)	Control list TD	This bit indicates whether TD exists in the control list. The host logic checks this bit when beginning the processing of the start ED in the control list. When this bit is 0, the host logic does not begin list processing. When this bit is 1, the host logic starts control list processing and clears this bit to 0. Upon detecting TD, the host logic restores this bit to 1 and continues control list processing. When the host logic completes list processing, it clears this bit to 0. If TD is not found in the list or software does not set this bit to 1, this bit remains at 0 and list processing stops. When creating a list again and executing processing of the list, set this bit before starting list processing by setting bit 4 (CLE) in the HcCommand register.	R/W
b2	BLF (BulkListFilled)	Bulk list TD	This bit indicates whether TD exists in the bulk list. The host logic checks this bit when beginning the processing of the start ED in the bulk list. When this bit is 0, the host logic does not begin list processing. When this bit is 1, the host logic starts bulk list processing and clears this bit to 0. Upon detecting TD, the host logic restores this bit to 1 and continues bulk list processing. When the host logic completes list processing, it clears this bit to 0. If TD is not found in the list or software does not set this bit to 1, this bit remains at 0 and list processing stops. When creating a list again and executing processing of the list, set this bit before starting list processing by setting bit 5 (BLE) in the HcCommand register.	R/W
b3	OCR (Ownership Change Request)	Host logic control right change	This bit changes the control right of the host logic. (For details, check with the OHCI specification).	W
b15 to b4	—	Reserved	When writing, write 0.	R/W
b17, b16	SOC[1:0] (Scheduling OverrunCount)	Schedule overrun count	These bits count the number of times a schedule overrun occurs. This value is incremented every time a schedule overrun occurs. When the value reaches 11b, it returns to 00b. Counting continues even while bit 0 (SO) in the HcInterruptStatus register is set.	R
b31 to b18	—	Reserved	When writing, write 0.	R/W

31.3.1.4 HcInterruptStatus Register

Address(es) A004 000Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	RHSC	FNO	UE	RD	SF	WDH	SO
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SO (Scheduling Overrun)	USB schedule overrun	This is an interrupt bit for indicating that the USB schedule has overrun in a frame. When the USB schedule overruns, this bit is set after HccaFrameNumber for the next frame is updated. When this bit is set, bits [17:16] (SOC) in the HcCommandStatus register are also incremented. Writing 1 to this bit clears the interrupt. 0: No SO interrupt has occurred. 1: SO interrupt has occurred.	R/W
b1	WDH (Writeback Done Head)	Host logic HccaDoneHead update	This is an interrupt bit for indicating that the host logic has updated the contents of HccaDoneHead. The host logic sets this bit immediately after updating HccaDoneHead, and does not update HccaDoneHead until this bit is cleared. Writing 1 to this bit clears the interrupt. 0: No WDH interrupt has occurred. 1: WDH interrupt has occurred.	R/W
b2	SF (StartOfFrame)	HccaFrameNumber update	This is an interrupt bit for indicating that HccaFrameNumber has been updated at the beginning of a frame. The host logic updates HccaFrameNumber and sets this bit when transmitting an SOF packet. Writing 1 to this bit clears the interrupt. 0: No SF interrupt has occurred. 1: SF interrupt has occurred.	R/W
b3	RD (Resume Detected)	Resume detection	This is an interrupt bit for indicating that Resume has been detected. This bit is set when assertion of the Resume signal by a device on the USB is detected. This bit is not set when software issues USB Resume. Writing 1 to this bit clears the interrupt. 0: No RD interrupt has occurred. 1: RD interrupt has occurred.	R/W
b4	UE (Unrecoverable Error)	USB Non-related system error detection	This is an interrupt bit for indicating that a system error on the PCI bus that is not related to the USB has been detected. Writing 1 to this bit clears the interrupt. 0: No UE interrupt has occurred. 1: UE interrupt has occurred.	R/W
b5	FNO (Frame Number Overflow)	FrameNumber bit MSB change	This is an interrupt bit for indicating that the MSB of bits [15:0] (FrameNumber) in the HcFmNumber register has changed. This bit is set after HccaFrameNumber is updated in the frame where the MSB of the FrameNumber bits changes from 0 to 1 or from 1 to 0. Writing 1 to this bit clears the interrupt. 0: No FNO interrupt has occurred. 1: FNO interrupt has occurred.	R/W

Bit	Symbol	Bit Name	Description	R/W
b6	RHSC (RootHubStatus Change)	HcRhStatus/HcRhPortStatus register status	This is an interrupt bit for indicating that the state of the HcRhStatus register or the HcRhPortStatus register has changed. This bit is set when the HcRhStatus or HcRhPortStatus register state is changed by a hardware source. Writing 1 to this bit clears the interrupt. 0: No RHSC interrupt has occurred. 1: RHSC interrupt has occurred.	R/W
b31 to b7	—	Reserved	When writing, write 0.	R/W

31.3.1.5 HcInterruptEnable Register

Address(es) A004 0010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MIE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	RHSCE	FNOE	UEE	RDE	SFE	WDHE	SOE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SOE (Scheduling OverrunEnable)	SO interrupt source enable	This bit enables SO as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: SO interrupt is enabled.	R/W
b1	WDHE (WritebackDone HeadEnable)	WDH interrupt source enable	This bit enables WDH as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: WDH interrupt is enabled.	R/W
b2	SFE (StartOfFrame Enable)	SF interrupt source enable	This bit enables SF as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: SF interrupt is enabled.	R/W
b3	RDE (Resume DetectedEnable)	RD interrupt source enable	This bit enables RD as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: RD interrupt is enabled.	R/W
b4	UEE (Unrecoverable ErrorEnable)	UE interrupt source enable	This bit enables UE as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: UE interrupt is enabled.	R/W
b5	FNOE (FrameNumber OverflowEnable)	FNO interrupt source enable	This bit specifies FNO as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: FNO interrupt is enabled.	R/W
b6	RHSCE (RootHubStatus ChangeEnable)	RHSC interrupt source enable	This bit enables RHSC as an interrupt source. To set this bit, write 1 to it. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: RHSC interrupt is enabled.	R/W
b30 to b7	—	Reserved	When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b31	MIE (MasterInterrupt Enable)	Interrupt 7 source enable	This bit enables interrupt source settings in bits [6:0] in this register. When this bit is 0, all interrupts are masked. To clear this bit, write 1 to the corresponding bit in the HcInterruptDisable register. 0: No monitoring and nothing is to be done. 1: The specified interrupt is enabled.	R/W

31.3.1.6 HcInterruptDisable Register

Address(es) A004 0014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MID	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

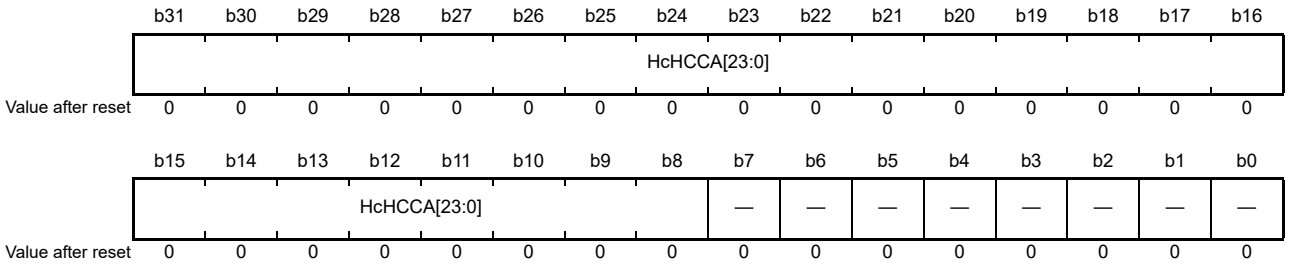
	—	—	—	—	—	—	—	—	—	RHSCD	FNOD	UED	RDD	SFD	WDHD	SOD
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SOD (Scheduling Overrun Disable)	SO interrupt source disable	This bit disables the interrupt source SO. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source SO is disabled.	R/W
b1	WDHD (Writeback DoneHead Disable)	WDH interrupt source disable	This bit disables the interrupt source WDH. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source WDH is disabled.	R/W
b2	SFD (StartOfFrame Disable)	SF interrupt source disable	This bit disables the interrupt source SF. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source SF is disabled.	R/W
b3	RDD (Resume Detected Disable)	RD interrupt source disable	This bit disables the interrupt source RD. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source RD is disabled.	R/W
b4	UED (Unrecoverable ErrorDisable)	UE interrupt source disable	This bit disables the interrupt source UE. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source UE is disabled.	R/W
b5	FNOD (FrameNumber Overflow Disable)	FNO interrupt source disable	This bit disables the interrupt source FNO. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source FNO is disabled.	R/W

Bit	Symbol	Bit Name	Description	R/W
b6	RHSCD (RootHub StatusChange Disable)	RHSC interrupt source disable	This bit disables the interrupt source RHSC. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt source RHSC is disabled.	R/W
b30 to b7	—	Reserved	When writing, write 0.	R/W
b31	MID (Master Interrupt Disable)	Interrupt 7 source disable	This bit disables interrupt source settings in bits [6:0] in HcInterruptEnable. When this bit is 0, all interrupts are masked. Write 1 to this bit to clear the corresponding bit in the HcInterruptEnable register. To enable the interrupt, write 1 to the corresponding bit in the HcInterruptEnable register. 0: Nothing is to be done. 1: The interrupt set is disabled.	R/W

31.3.1.7 HcHCCA Register

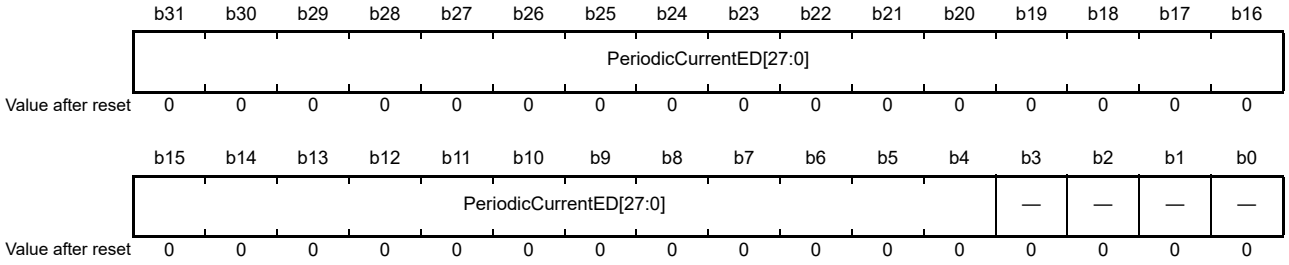
Address(es) A004 0018h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	When writing, write 0.	R/W
b31 to b8	HcHCCA [23:0]	RAM base address setting	These bits specify the base address of the RAM allocated to the host controller communication area. Specify a value in these bits during initialization. The host logic requests a 256-byte area starting from the base address specified in these bits as HCCA.	R/W

31.3.1.8 HcPeriodicCurrentED Register

Address(es) A004 001Ch



Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	Don't care	R
b31 to b4	Periodic CurrentED [27:0]	ED physical address	These bits indicate the physical address of the current ED being processed in the periodic list. The host logic updates these bits when completing the ED list processing.	R

31.3.1.9 HcControlHeadED Register

Address(es) A004 0020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ControlHeadED[27:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ControlHeadED[27:0]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	When writing, always write 0.	R/W
b31 to b4	Control HeadED [27:0]	Start ED physical address specifying	These bits specify the physical address of the start ED in the control list. To execute control transfer, set up these bits before setting the CLE bit in the HcControl register.	R/W

31.3.1.10 HcControlCurrentED Register

Address(es) A004 0024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ControlCurrentED[27:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ControlCurrentED[27:0]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	When writing, always write 0.	R/W
b31 to b4	Control CurrentED [27:0]	ED physical address	These bits indicate the physical address of the current ED being processed in the control list. The host logic updates these bits every time the control ED processing is completed. When creating a new list, set these bits to 0000 0000h, which indicates the end of the list. When transfer is temporarily stopped and then restarted, make sure that the ED indicated by the link pointer in ControlCurrentED exists.	R/W

31.3.1.11 HcBulkHeadED Register

Address(es) A004 0028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BulkHeadED[27:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BulkHeadED[27:0]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	When writing, always write 0.	R/W
b31 to b4	BulkHeadED [27:0]	Start ED physical address specifying	These bits specify the physical address of the start ED in the bulk list. To execute bulk transfer, set up these bits before setting bit 5 (BLE) in the HcControl register.	R/W

31.3.1.12 HcBulkCurrentED Register

Address(es) A004 002Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BulkCurrentED[27:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BulkCurrentED[27:0]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	When writing, always write 0.	R/W
b31 to b4	BulkCurrentED [27:0]	ED physical address	These bits indicate the physical address of the current ED being processed in the bulk list. The host logic updates these bits every time the bulk ED processing is completed. When creating a new list, set these bits to 0000 0000h, which indicates the end of the list. When transfer is temporarily stopped and then restarted, make sure that the ED indicated by the link pointer in BulkCurrentED exists.	R/W

31.3.1.13 HcDoneHead Register

Address(es) A004 0030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DoneHead[27:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DoneHead[27:0]												—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	Don't care	R
b31 to b4	DoneHead [27:0]	HcDoneHead physical address	These bits indicate the physical address of HcDoneHead in the host logic. This is the physical address of the last completed TD to be added to the Done queue.	R

31.3.1.14 HcFmInterval Register

Address(es) A004 0034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	FIT	FSMPS[14:0]														
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FI[13:0]													
Value after reset	0	0	1	0	1	1	1	0	1	1	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	FI[13:0] (FrameInterval)	Frame interval setting	These bits specify the length (bit time) of a frame used for FS transfer. To conform to the USB standard (one frame = 1 ms), set these bits to 2EDFh.	R/W
b15, b14	—	Reserved	When writing, always write 0.	R/W
b30 to b16	FSMPS[14:0] (FSLagest DataPacket)	FSt transfer packet maximum size setting	These bits specify the maximum amount of data that can be transferred without generating a schedule overrun. This setting is compared with the current location in the frame to determine up to which data in the frame can be transferred. The maximum amount depends on the system bus performance, and it should be specified by the driver.	R/W
b31	FIT (FrameInterval Toggle)	Frame synchronization	This bit is used to match the frame settings between software and the host logic. When updating the FI bits, software should toggle this bit. When loading the FI bit value, the host logic copies the FIT value to bit 31 (FRT) in the HcFmRemaining register. Software can check if the new FI bit setting has been reflected by comparing the value specified in this bit when the FI bits are written to, and the value read from the FRT bit.	R/W

31.3.1.15 HcFmRemaining Register

Address(es) A004 0038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	FRT	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	FR[13:0]													
Value after reset	0	0	1	0	1	1	1	0	1	1	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	FR[13:0] (Frame Remaining)	Down counter frame	These are the register bits of a 14-bit down counter which counts down the current remaining time value during transmission of a frame. That is, the value of these bits is decremented over time. When the value reaches 0000h, these bits are reloaded with the frame interval value by copying this value from bits [13:0] (FI) in the HcFmInterval register, after which counting down is restarted.	R
b30 to b14	—	Reserved	Don't care	R
b31	FRT (Frame Remaining Toggle)	Frame synchronization	This bit is used to match the frame settings between software and the host logic. When the FR bits reach 0000h, the host logic copies the value of bits [13:0] (FI) in the HcFmInterval register to the FR bits and also copies the value of bit 31 (FIT) in the HcFmInterval register to this bit. Software can check if the FI bit setting has been copied to the FR bits by comparing the values of the FIT bit and this bit.	R

31.3.1.16 HcFmNumber Register

Address(es) A004 003Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FrameNumber[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	FrameNumber [15:0]	Elapsed frame number	These bits indicate the elapsed frame count. The count in these bits is incremented when the value of bits [13:0] (FR) in the HcFmRemaining register reaches 0000h.	R
b31 to b16	—	Reserved	Don't care	R

31.3.1.17 HcPeriodicStart Register

Address(es) A004 0040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	PeriodicStart[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	PeriodicStart [13:0]	Periodic list processing start time	These bits indicate the time when the host logic starts periodic list processing in a frame. Specify a value in these bits by software during initialization of the host logic. When the value of bits [13:0] (FR) in the HcFmRemaining register is greater than the value specified in these bits, non-periodic lists take priority over periodic lists. The OHCI standard recommends that this value be set to about 90% of the value of bits [13:0] (FI) in the HcFmInterval register. Therefore, the recommended value is 2A2Fh	R/W
b31 to b14	—	Reserved	When writing, write 0.	R/W

31.3.1.18 HcRhDescriptorA Register

Address(es) A004 0048h

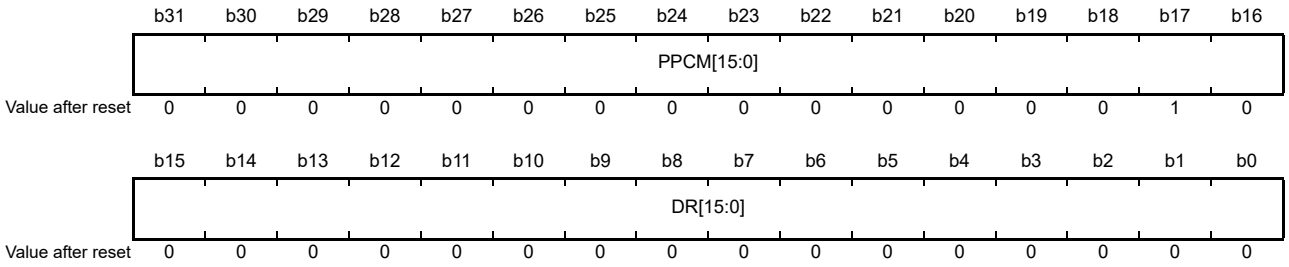
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	POTPGT[7:0]								—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	NOCP	OCPM	DT	NPS	PSM	NDP[7:0]							
Value after reset	0	0	0	0	1	0	0	1	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	NDP[7:0] (Number Downstream Port)	Downstream port number	These bits specify the number of downstream ports supported by the root hub in the host logic.	R
b8	PSM (PowerSwitchingMode)	Power switch control	This bit specifies how to control the power switch to each port of the root hub. While bits [31:16] (PPCM) in the HcRhDescriptorB register are set, each port responds only to Set/ClearPortPower. While the bits are cleared, each port is controlled by Set/ClearGlobalPower. This bit setting is valid only when the NPS bit is cleared. 0: Power to all ports is controlled together. 1: Power to each port is separately controlled.	R/W
b9	NPS (NoPower Switching)	Power control	This bit specifies how to control the port power. 0: Port power can be switched on and off. 1: Port power is always turned on while the host logic is operating.	R/W
b10	DT (DeviceType)	Device type	This bit indicates that the root hub is not a compound device. As the root hub is not allowed to be a compound device, this bit is always read as 0.	R
b11	OCPM (OverCurrent Protection Mode)	Overcurrent state reporting	This bit specifies how to report the overcurrent state of the root hub. This bit should be set to the same mode as that specified in the PSM bit. This setting is valid only when the NOCP bit is cleared. 0: Overcurrent state of all ports is collectively reported. 1: Overcurrent state of each port is separately reported.	R/W
b12	NOCP (NoOver Current Protection)	Overcurrent function support	This bit specifies whether to support the overcurrent protection function for the root hub. 0: Overcurrent protection function is supported. 1: Overcurrent protection function is not supported.	R/W
b23 to b13	—	Reserved	When writing, write 0.	R/W
b31 to b24	POTPGT[7:0] (PowerOnTo PowerGood Time)	Wait time	These bits indicate the time that software should wait before accessing a root hub port after power supply to the port is started. The unit of time is 2 ms. Therefore, the wait time is obtained by POTPGT × 2 ms.	R/W

31.3.1.19 HcRhDescriptorB Register

Address(es) A004 004Ch



Bit	Symbol	Bit Name	Description	R/W
b0	DR[15:0] (Device Removable)	Device removable	These bits indicate whether the device connected to each port in the root hub is removable. Each bit is dedicated to a single port. The USB host controller has port 1 only.	R
b1				R/W
b15 to b2				R

Bit	Value	Description
0	—	Reserved
1	0	Device connected to port 1 is not removable.
	1	Device connected to port 1 is removable.
[15:2]	—	Reserved

b16	PPCM[15:0] (PortPower ControlMask)	Power control command	These bits specify power control commands for each port. This setting is valid when bit 8 (PSM) in the HcRhDescriptorA register is set. Each bit is dedicated to a single port. The USB host controller has port 1 only.	R
b17				R/W
b31 to b18				R

Bit	Value	Description
0	—	Reserved
1	0	All ports are collectively controlled (Set/ClearGlobalPower).
	1	Port 1 is separately controlled (Set/ClearPortlPower).
[15:2]	—	Reserved

31.3.1.20 HcRhStatus_A, HcRhStatus_B Register

(1) HcRhStatus_A Register

Address(es) A004 0050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCIC	SGP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCI	CGP
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CGP (ClearGlobal Power)	Global power clear	Setting this bit to 1 turns off the power to a port. The port to be turned off is determined according to the settings of bit 8 (PSM) in the HcRhDescriptorA register and bits [31:16] (PPCM) in the HcRhDescriptorB register. The USB host controller has port 1 only.	W
b1	OCI (OverCurrent Indicator)	Overcurrent indicator	This bit reports the overcurrent state in global overcurrent detection mode. When overcurrent is reported separately for each port, this value is always 0. 0: Port is in normal state. 1: Port is in overcurrent state.	R
b14 to b2	—	Reserved	When writing, write 0.	R/W
b15	SRWE (SetRemote Wakeup Enable)	DRWE bit enable	This bit sets the DRWE bit. Setting this bit sets the DRWE bit. Writing 0 has no effect.	W
b16	SGP (SetGlobal Power)	Port power setting	Setting this bit to 1 turns on the power to a port. The port to be turned on is determined according to the settings of bit 8 (PSM) in the HcRhDescriptorA register and bits [31:16] (PPCM) in the HcRhDescriptorB register. The USB host controller has port 1 only.	W

value	PSM	PPCM[1]	Description
0	—	—	No Change
1	0	—	The PPS bit in the HcRhPortStatus1 register is cleared.
	1	0	The PPS bit in the HcRhPortStatus1 register is cleared.
		1	No Change

value	PSM	PPCM[1]	Description
0	—	—	No Change
1	0	—	The PPS bit in the HcRhPortStatus1 register is set.
	1	0	The PPS bit in the HcRhPortStatus1 register is set.
		1	No Change

Bit	Symbol	Bit Name	Description	R/W
b17	OCIC (OverCurrent Indicate Change)	OCI bit change report	This bit notifies that the OCI bit value has changed. It is set when the OCI bit changes. Writing 1 to this bit while it is set to 1 clears it. Writing 0 has no effect. 0: Nothing is to be done in case of an overcurrent. 1: OverCurrent state has changed.	R/W
b30 to b18	—	Reserved	When writing, write 0.	R/W
b31	CRWE (Clear Remote Wakeup Enable)	DRWE bit clear	This bit clears the DRWE bit. Setting this bit clears the DRWE bit. Writing 0 has no effect.	W

(2) HcRhStatus_B Register

Address(es) A004 0050h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCIC	LPSC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DRWE	—	—	—	—	—	—	—	—	—	—	—	—	—	OCI	LPS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LPS (LocalPower Status)	Local power status	This product does not support the local power status function; this bit is always read as 0.	R
b1	OCI (OverCurrent Indicator)	Overcurrent indicator	This bit reports the overcurrent state in global overcurrent detection mode. When overcurrent is reported separately for each port, this value is always 0. 0: Port is in normal state. 1: Port is in overcurrent state.	R
b14 to b2	—	Reserved	When writing, write 0.	R/W
b15	DRWE (Device Remote Wakeup Enable)	Device remote start enable	This bit specifies whether to include bit 16 (CSC) in the HcRhPortStatus1 register as a remote wakeup event. When a connect status change event occurs while this bit is set, transition from the USB suspend state to the USB resume state occurs and the resume detect interrupt is generated. 0: ConnectStatusChange is not a RemoteWakeup source. 1: ConnectStatusChange is a RemoteWakeup source.	R
b16	LPSC (LocalPower Status Change)	Local power status change	This product does not support the local power status function and this bit is always read as 0.	R
b17	OCIC (OverCurrent Indicate Change)	OCI bit change report	This bit notifies that the OCI bit value has changed. It is set when the OCI bit changes. Writing 1 to this bit while it is set to 1 clears it. Writing 0 has no effect. 0: Nothing is to be done in case of an overcurrent. 1: OverCurrent state has changed.	R/W
b30 to b18	—	Reserved	When writing, write 0.	R/W
b31	CRWE (Clear Remote Wakeup Enable)	DRWE bit clear	This bit clears the DRWE bit. Setting this bit clears the DRWE bit. Writing 0 has no effect.	W

31.3.1.21 HcRhPortStatus1_A, HcRhPortStatus1_B Register

(1) HcRhPortStatus1_A Register

Address(es) A004 0054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	PRSC	OCIC	PSSC	PESC	CSC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	CPP	SPP	—	—	—	SPR	CSS	SPS	SPE	CPE
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CPE (ClearPort Enable)	PES bit clear	This bit is used to clear the PES bit. Writing 1 makes the port enter the disabled state. Writing 0 has no effect.	W
b1	SPE (SetPort Enable)	PES bit enable	This bit is used to set the PES bit. Writing 1 makes the port enter the enabled state. Writing 0 has no effect. Note 1. To control port state transition, use bit 4 (SPR) in the HcRhPortStatus1_A register. The OHCI standard supports use of the SPE bit to make the port enter the enabled state, but the USB standard does not support this.	W
b2	SPS (SetPort Suspend)	Port state Suspend transition	This bit shifts the port to the suspend state. Writing 1 makes the port enter the suspend state. Writing 0 has no effect. If this bit is written to while the CCS bit is cleared, the CSC bit is set to notify the driver of an attempt to suspend a disconnected port.	W
b3	CSS (ClearSuspend Status)	Suspend clear	This bit terminates the suspend state and starts the Resume sequence. Writing 1 starts the Resume sequence. Writing 0 has no effect. The Resume sequence starts only while the PSS bit is set.	W
b4	SPR (SetPortReset)	Port reset issuing	This bit applies a port reset to a downstream port. Writing 1 to this bit starts a 10-ms port reset. If this bit is written to while the CCS bit is cleared, the PRS bit will not be set. Instead, the CSC bit is set to notify software of an attempt to reset a port where no device is connected. Writing 0 has no effect.	W
b7 to b5	—	Reserved	When writing, write 0.	R/W
b8	SPP (SetPort Power)	Port power-on	This bit turns on the port power when power is separately controlled for each port. Writing 1 turns on the port. Writing 0 has no effect.	W
b9	CPP (ClearPort Power)	Port power clear	This bit turns off the port power when power is separately controlled for each port. Writing 1 turns off the port. Writing 0 has no effect.	W
b15 to b10	—	Reserved	When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b16	CSC (ConnectStatus Change)	CCS bit status	This bit indicates that the CCS bit value has changed. The host logic sets this bit when the CCS bit changes due to device connection or disconnection. In addition, when a request for port reset, port suspension, or port enable is issued in the disconnection state, this bit is set to make software re-evaluate the device connection state. It is cleared when 1 is written by software. 0: Nothing is to be done regarding CCS. 1: CCS has changed.	R/W
b17	PESC (PortEnable StatusChange)	PES bit status	This bit indicates that the PES bit value has changed. It is set when the port state has changed due to a hardware event, such as the overcurrent state, disconnection, power-off, or a babble error. It is cleared when 1 is written by software. 0: Nothing is to be done regarding PES. 1: PES state has changed.	R/W
b18	PSSC (PortSuspend StatusChange)	RESUME sequence complete	This bit indicates that the RESUME sequence has been completed. It is set when all RESUME processing by hardware has been completed. It is cleared when 1 is written by software. In addition, it is cleared when the PRSC bit is set. 0: RESUME has not been completed. 1: RESUME has been completed.	R/W
b19	OCIC (OverCurrent IndicateChange)	Overcurrent state detection	This bit is set when the overcurrent state of the port has been detected. It is valid only while the overcurrent state is reported separately for each port (OCPM = 1 in the HcRhDescriptorA register). It is cleared when 1 is written by software. 0: Nothing is to be done regarding overcurrent state. 1: Overcurrent state has changed.	R/W
b20	PRSC (PortReset StatusChange)	Port reset complete	This bit indicates that a port reset has been completed. It is set when the host logic has completed a 10-ms hardware reset. It is cleared when 1 is written by software. 0: Port reset has not been completed, or nothing is to be done regarding the PRS bit. 1: Port reset has been completed.	R/W
b31 to b21	—	Reserved	When writing, write 0.	R/W

(2) HcRhPortStatus1_B Register

Address(es) A004 0054h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	PRSC	OCIC	PSSC	PESC	CSC
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	LSDA	PPS	—	—	—	PRS	POCI	PSS	PES	CCS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CCS (Current ConnectStatus)	Connection status indication	This bit indicates the current connection state of the downstream port. 0: No device is connected. 1: Device is connected.	R
b1	PES (PortEnable Status)	Port state enable status	This bit indicates whether the port is enabled or disabled. The host logic automatically clears this bit upon detecting the overcurrent state, disconnection, power-off, or a babble error. At this time, the PESC bit is set. This bit cannot be set while the CCS bit is cleared (no device is connected). The host logic sets this bit when a port reset is completed or suspension of the port is terminated. 0: Port is disabled. 1: Port is enabled.	R
b2	PSS (PortSuspend Status)	Suspend/Resume status	This bit indicates that the port is in the suspend state or the Resume sequence. Writing to the SPS bit sets this bit. This bit is not set while the CCS bit is cleared (no device is connected). This bit is cleared with the following timing: • When the Resume sequence is completed and the PSSC bit is set. • When a port reset is completed and the PRSC bit is set. • In the USB RESUME state. 0: Port is in normal transfer state. 1: Port is in suspend state.	R
b3	POCI (PortOver Current Indicator)	Downstream port overcurrent detection	This bit indicates that a downstream port has entered the overcurrent state. It is valid only while the overcurrent state is reported separately for each port (OCPM = 1 in the HcRhDescriptorA register). While the overcurrent state in all ports is collectively reported, this bit is 0b. 0: Port is in normal state. 1: Port is in overcurrent state.	R
b4	PRS (PortReset Status)	Port reset status	This bit indicates the reset state of the port. It is cleared at the same time as when the PRSC bit is set after a 10-ms port reset is completed. This bit cannot be set while the CCS bit is cleared (device is not connected). 0: Port reset is not in progress. 1: Port reset is in progress.	R
b7 to b5	—	Reserved	When writing, write 0.	R/W
b8	PPS (PortPower Status)	Power status	This bit indicates the power state of the port. It is cleared when an overcurrent is detected. 0: Port power is off. 1: Port power is on.	R

Bit	Symbol	Bit Name	Description	R/W
b9	LSDA (LowSpeed DeviceAttached)	Device speed	This bit indicates the speed of the device connected to the port. This status bit is valid only while the CCS bit is set. 0: FS device is connected. 1: LS device is connected.	R
b15 to b10	—	Reserved	When writing, write 0.	R/W
b16	CSC (ConnectStatus Change)	CCS bit status	This bit indicates that the CCS bit value has changed. The host logic sets this bit when the CCS bit changes due to device connection or disconnection. In addition, when a request for port reset, port suspension, or port enable is issued in the disconnection state, this bit is set to make software re-evaluate the device connection state. It is cleared when 1 is written by software. 0: Nothing is to be done regarding CCS. 1: CCS has changed.	R/W
b17	PESC (PortEnable StatusChange)	PES bit status	This bit indicates that the PES bit value has changed. It is set when the port state has changed due to a hardware event, such as the overcurrent state, disconnection, power-off, or a babble error. It is cleared when 1 is written by software. 0: Nothing is to be done regarding PES. 1: PES state has changed.	R/W
b18	PSSC (PortSuspend StatusChange)	RESUME sequence complete	This bit indicates that the RESUME sequence has been completed. It is set when all RESUME processing by hardware has been completed. It is cleared when 1 is written by software. In addition, it is cleared when the PRSC bit is set. 0: RESUME has not been completed. 1: RESUME has been completed.	R/W
b19	OCIC (OverCurrent IndicateChange)	Overcurrent state detection	This bit is set when the overcurrent state of the port has been detected. It is valid only while the overcurrent state is reported separately for each port (OCPM = 1 in the HcRhDescriptorA register). It is cleared when 1 is written by software. 0: Nothing is to be done regarding overcurrent state. 1: Overcurrent state has changed.	R/W
b20	PRSC (PortReset StatusChange)	Port reset complete	This bit indicates that a port reset has been completed. It is set when the host logic has completed a 10-ms hardware reset. It is cleared when 1 is written by software. 0: Port reset has not been completed, or nothing is to be done regarding the PRS bit. 1: Port reset has been completed.	R/W
b31 to b21	—	Reserved	When writing, write 0.	R/W

31.3.2 EHCI Operational Registers

Access the EHCI operational registers after starting up the PHY internal PLL. For details, see Figure 31.13, Initial Setting Sequence.

31.3.2.1 HCIVERSION/CAPLENGTH Register

Address(es) A004 1000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Interface Version Number[15:0]															
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	Capability Registers Length[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Capability Registers Length [7:0]	Host logic operational register start address	These bits indicate the start address of the host logic operational registers. As the host logic operational registers are allocated from address 20h, this value is set to 20h.	R
b15 to b8	—	Reserved	Don't care	R
b31 to b16	Interface Version Number [15:0]	EHCI version	These bits indicate the version of the EHCI specifications supported by the host logic. As the host logic conforms to the EHCI Rev. 1.0, this value is set to 0100h.	R

31.3.2.2 HCSPARAMS Register

Address(es) A004 1004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	Debug Port Number[3:0]				—	—	—	P_INDICATOR
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	N_CC[3:0]				N_PCC[3:0]				Port Routing Rules	—	—	PPC	N_PORTS[3:0]			
Value after reset	0	0	0	1	0	0	0	1	1	0	0	1	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	N_PORTS [3:0] (Number of Ports)	Number of downstream port	These bits indicate the number of physical downstream ports used by the host logic. These bits reflect the setting of bits [1:0] (Port_no) in the PCI Configuration EXT1 register. As the USB host controller has only one port, this value is set to 1h.	R
b4	PPC (Port Power Control)	Port power control	This bit indicates how to control the port power in the host logic. As the USB host controller supports the power supply control function, this value is set to 1.	R
b6, b5	—	Reserved	Don't care	R
b7	Port Routing Rules	Port routing rules	This bit indicates how ports are mapped in the OHCI host logic. As the value of the HCSP_PORTROUTE register shows the mapping in the host logic, this value is set to 1h.	R
b11 to b8	N_PCC[3:0] (Number of Ports per Companion Controller)	Number of Port	These bits indicate the number of the port supported by one OHCI host logic unit. These bits reflect the setting of bits [1:0] (Port_no) in the PCI Configuration EXT1 register. As the USB host controller has only one port, this value is set to 1h.	R
b15 to b12	N_CC[3:0] (Number of Companion Controller)	Number of OHCI host logic	These bits indicate the number of OHCI host logic units related to the EHCI host logic. As the host logic has one OHCI host logic unit, this value is set to 1h.	R
b16	P_INDICATOR	Port indicator control support	This bit indicates whether the host logic supports the port indicator control function. As the host logic does not support the port indicator control function, this value is set to 0.	R
b19 to b17	—	Reserved	Don't care	R
b23 to b20	Debug Port Number[3:0]	Debug port number	These bits indicate that the host logic ports are debug ports. As the host logic has no debug ports, this value is set to 0000b.	R
b31 to b24	—	Reserved	Don't care	R

31.3.2.3 HCCPARAMS Register

Address(es) A004 1008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EECP[7:0]								IST[3:0]				—	ASPC	PFLF	AC64
Value after reset	1	1	1	0	1	0	0	0	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	AC64	Memory pointer selection	This bit indicates whether data structures use 32-bit address memory pointers or 64-bit address memory pointers. As the host logic supports data structures using 32-bit address memory pointers, this value is set to 0. 64-bit address memory pointers are not supported.	R
b1	PFLF	Programming frame list flag	This bit indicates the setting regarding the frame list size that software can use. This value is set to 1 in this host logic. When this bit is set to 1, the available frame list size can be specified through bits [3:2] (Frame List Size) in the USBCMD register. A frame list size smaller than 4 Kbytes can be specified.	R
b2	ASPC	Asynchronous schedule park support capability	This bit indicates whether to support the park mode for the high-speed QH (queue head) in the asynchronous schedule. As the host logic supports this function, this value is set to 1.	R
b3	—	Reserved	Don't care	R
b7 to b4	IST[3:0]	Isochronous data structure threshold	As the host logic in this product does not support caching of the isochronous data structure in the entire frame, these bits are set to 0h.	R
b15 to b8	EECP[7:0] (EHCI Extend Capabilities Pointer)	Offset address	These bits indicate the offset address for the EHCI extend capabilities registers. This indicates that extend registers are placed at addresses starting from E8h in the EHCI configuration space. As the host logic does not support the legacy function, the value read from these bits has no meaning.	R
b31 to b16	—	Reserved	Don't care	R

31.3.2.4 HCSP_PORTROUTE Register

Address(es) A004 100Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Companion Port Route[31:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Companion Port Route[31:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	Companion Port Route[31:0]	OHCI Host Port Indication	These bits indicate the ports that the OHCI host logic controls. As the host logic has one OHCI host logic unit, these bits are set to 0000 0000h.	R

31.3.2.5 USBCMD Register

Address(es) A004 1020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	Interrupt Threshold Control[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	Asynchronous Schedule Park Mode Enable	—	ASPMC[1:0]		Light Host Controller Reset	Interrupt on Async Advance Doorbell	ASPME	Periodic Schedule Enable	Frame List Size[1:0]		HCRESET	RS
Value after reset	0	0	0	0	1	0	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RS (Run/Stop)	EHCI host logic run/stop	This bit activates or stops the EHCI host logic. When this bit is set to 1, the host logic starts operation. As long as this value is 1, the host logic continues operation. Note that this bit should be set to 1 only while the host logic is in the halt state. Bit 12 (HCHalted) in the USBSTS register indicates that the host logic has completed transactions and entered the halt state. 0: Stopped (the host logic has completed transactions and halted). 1: Activated (the host logic executes the schedule).	R/W
b1	HCRESET (Host Controller Reset)	Host logic initialization	This bit initializes the host logic. When this bit is set to 1, the host logic initializes the internal pipelines and state machine. Communication through the USB stops immediately. A USB reset is not issued to downstream ports at this time. This reset does not initialize the PCI configuration registers, but it initializes the EHCI operational registers and the port ownership is returned to OHCI. This bit is automatically cleared to 0 by the host logic when the reset is completed. The reset cannot be aborted by software by writing 0 to this bit. This bit should be set only while bit 12 (HCHalted) in the USBSTS register is 1.	R/W
b3, b2	Frame List Size[1:0]	Frame list size	These bits specify the frame list size. The setting in these bits determines the size of the Frame List Current index in the FRINDEX register. b3 b2 0 0: 1024 elements (4096 bytes) 0 1: 512 elements (2048 bytes) 1 0: 256 elements (1024 bytes) 1 1: Reserved	R/W
b4	Periodic Schedule Enable	Periodic schedule enable	This bit specifies whether to advance or skip periodic list processing. 0: Periodic list processing is not executed (skipped). 1: Periodic list processing is executed using the PERIODICLISTBASE register. Note: For transferring data via USB while this bit is being 0, set b12 of the EXT1 register to 0. For details, see section 31.3.3.12, Offset E0h Register (EXT1).	R/W
b5	ASPME	Asynchronous schedule enable	This bit specifies whether to advance or skip asynchronous list processing. 0: Asynchronous list processing is not executed (skipped). 1: Asynchronous list processing is executed using the ASYNCLISTADDR register.	R/W

Bit	Symbol	Bit Name	Description	R/W
b6	Interrupt on Async Advance Doorbell	Doorbell	This bit is used as a doorbell by software. Software sets this bit to 1 to generate an interrupt when processing proceeds with the next QH (queue head). While bit 5 (Interrupt on Async Advance Enable) in the USBINTR register is set to 1, an interrupt is generated with the next interrupt timing after 1 is written to this bit. If this bit is set while bit 5 (Interrupt on Async Advance Enable) in the USBINTR register is 0, correct operation is not guaranteed. This bit is cleared by the host logic. Upon completing the processing of a QH normally, the host logic clears this bit to 0 and sets bit 5 (Interrupt on Async Advance) in the USBSTS register to 1.	R/W
b7	Light Host Controller Reset	Light host controller reset execution status	This bit indicates the state of Light Host Controller Reset execution. As the host logic does not support Light Host Controller Reset, this value is fixed to 0.	R
b9, b8	ASPMC[1:0]	Asynchronous schedule park transaction count	These bits specify the number of transactions that can be executed in succession from one QH (queue head). A value from 1h to 3h can be specified. This setting is valid when bit 11 (Asynchronous Schedule Park Mode Enable) is 1.	R/W
b10	—	Reserved	When writing, write 0.	R/W
b11	Asynchronous Schedule Park Mode Enable	Park mode enable	This bit enables or disables the park mode. 0: Disabled 1: Enabled	R/W
b15 to b12	—	Reserved	When writing, write 0.	R/W
b23 to b16	Interrupt Threshold Control[7:0]	Host logic interrupt generation maximum rate	These bits indicate the maximum rate at which the host logic generates an interrupt. Correct operation is not guaranteed if a value not shown below is written to these bits. 00h: Reserved 01h: 1 micro-frame 02h: 2 micro-frames 04h: 4 micro-frames 08h: 8 micro-frames (1 ms) 10h: 16 micro-frames (2 ms) 20h: 32 micro-frames (4 ms) 40h: 64 micro-frames (8 ms)	R/W
b31 to b24	—	Reserved	When writing, write 0.	R/W

31.3.2.6 USBSTS Register

Address(es) A004 1024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Asynchronous Schedule Status	Periodic Schedule Status	Reclamation	HCHalted	—	—	—	—	—	—	Interrupt on Async Advance	Host System Error	Frame List Rollover	Port Change Detect	USBERRINT	USBINT
Value after reset	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	USBINT (USB Interrupt)	USB transfer complete	This bit indicates that USB transfer has been completed. The host logic sets this bit to 1 when either of the following conditions is satisfied. • USB transfer is completed • A short packet is received Even if USB transfer has ended with an error, this bit is set to 1 when the IOC (Interrupt On Complete) bit in the TD is 1. Writing 1 can clear this bit. Writing 0 has no effect. 0: USB transfer has not been completed. 1: USB transfer has been completed.	R/W
b1	USBERRINT (USB Error Interrupt)	USB transaction status	This bit indicates that a USB transaction has ended with an error. The host logic sets this bit to 1 when a USB transaction has ended with an error. Such an error includes the case when the error counter underflows. Writing 1 can clear this bit. Writing 0 has no effect. 0: USB transaction has been completed normally. 1: USB transaction has ended with an error.	R/W
b2	Port Change Detect	Port state change detection	This bit indicates that the port state has changed. The host logic sets this bit to 1 when any of the following conditions is satisfied in a port for which bit 13 (Port Owner) in the PORTSC[n] register is set to 0. [1 setting condition] • Bit 1 (Connect Status Change) in the PORTSC[n] register has changed from 0 to 1. (Device connection or disconnection has been detected.) • Bit 3 (Port Enable/Disable Change) in the PORTSC[n] register has changed from 0 to 1. (The port enabled state has changed.) • Bit 5 (Over-current Change) in the PORTSC[n] register has changed from 0 to 1. (The overcurrent state has been detected.) • Bit 6 (Force Port Resume) in the PORTSC[n] register has changed from 0 to 1. (indicating detection of a J-to-K transition on a port while suspended.) Writing 1 by software can clear this bit. Writing 0 has no effect.	R/W
b3	Frame List Rollover	Frame list rollover	The host logic sets this bit to 1 when the value of the Frame Index bits in the FRINDEX register returns from the maximum value to 000h (rollover). The maximum value at which rollover occurs depends on bits [3:2] (Frame List Size) in the USBCMD register. Writing 1 can clear this bit. Writing 0 has no effect. 0: Frame list has not returned to 000h. 1: Frame list has returned to 000h.	R/W

Bit	Symbol	Bit Name	Description	R/W
b4	Host System Error	Host system error	This bit is set to 1 when a serious error occurs in the host logic. Such an error includes a parity error in the PCI system. If this error occurs, the host logic clears bit 0 (RS) in the USBCMD register to 0 to stop execution of the remaining TDs. Writing 1 can clear this bit. Writing 0 has no effect. 0: No system error has occurred. 1: System error has occurred.	R/W
b5	Interrupt on Async Advance	Async advance interrupt status	This bit indicates the Async Advance interrupt state. Upon fetching QH, the host logic checks bit 6 (Interrupt on Async Advance Doorbell (IAAD)) in the USBCMD register. When the IAAD bit is 1, the host logic clears the IAAD bit and sets this bit after completing QH processing normally. When bit 5 (Interrupt on Async Advance Enable) in the USBINTR register is 1, an interrupt is generated from this source with the next interrupt timing after this bit is set to 1. Writing 1 can clear this bit. Writing 0 has no effect. 0: No Async Advance interrupt has occurred. 1: Async Advance interrupt state has been detected.	R/W
b11 to b6	—	Reserved	When writing, write 0.	R/W
b12	HCHalted	EHCI host logic status	This bit is set to 0 when bit 0 (RS) in the USBCMD register is 1. When the RS bit is cleared to 0 by the host logic or software, the EHCI host logic stops execution and this bit is set to 1 by the host logic. 0: EHCI host logic is in execution. 1: EHCI host logic is stopped.	R
b13	Reclamation	Empty asynchronous schedule detection	This bit is used to detect an empty asynchronous schedule. The host logic clears this bit to 0 after a reset or when it fetches QH with H = 1. When the host logic executes an asynchronous transaction or has detected a start event, it sets this bit to 1. When the host logic fetches QH with H = 1b while this bit is 0, the Async Sched Sleeping mode is entered.	R
b14	Periodic Schedule Status	Periodic schedule status	This bit indicates the current state of the periodic schedule. The periodic schedule is enabled (1) or disabled (0) when the values of this bit and bit 4 (Periodic Schedule Enable) in the USBCMD register are the same. 0: Periodic schedule is disabled. 1: Periodic schedule is enabled.	R
b15	Asynchronous Schedule Status	Asynchronous schedule status	This bit indicates the current state of the asynchronous schedule. The asynchronous schedule is enabled (1) or disabled (0) when the values of this bit and bit 5 (ASPME) in the USBCMD register are the same. 0: Asynchronous schedule is disabled. 1: Asynchronous schedule is enabled.	R
b31 to b16	—	Reserved	When writing, write 0.	R/W

31.3.2.7 USBINTR Register

Address(es) A004 1028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	—	—	—	—	—	—	—	—	—	—	Interrupt on Async Advance Enable	Host System Error Enable	Frame List Rollover Enable	Port Change Interrupt Enable	USB Error Interrupt Enable	USB Interrupt Enable
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	USB Interrupt Enable	USB interrupt enable	This bit enables or disables the setting in bit 0 (USBINT) in the USBSTS register. To clear the interrupt, use the USBINT bit. 0: Disabled 1: Enabled	R/W
b1	USB Error Interrupt Enable	USB error interrupt enable	This bit enables or disables the setting in bit 1 (USBERRINT) in the USBSTS register. To clear the interrupt, use the USBERRINT bit. 0: Disabled 1: Enabled	R/W
b2	Port Change Interrupt Enable	Port change interrupt enable	This bit enables or disables the setting in bit 2 (Port Change Detect) in the USBSTS register. To clear the interrupt, use the Port Change Detect bit. 0: Disabled 1: Enabled	R/W
b3	Frame List Rollover Enable	Frame list rollove enable	This bit enables or disables the setting in bit 3 (Frame List Rollover) in the USBSTS register. To clear the interrupt, use the Frame List Rollover bit. 0: Disabled 1: Enabled	R/W
b4	Host System Error Enable	Host system error enable	This bit enables or disables the setting in bit 4 (Host System Error) in the USBSTS register. To clear the interrupt, use the Host System Error bit. 0: Disabled 1: Enabled	R/W
b5	Interrupt on Async Advance Enable	Interrupt on async advance enable	This bit enables or disables the setting in bit 5 (Interrupt on Async Advance) in the USBSTS register. To clear the interrupt, use the Interrupt on Async Advance bit. 0: Disabled 1: Enabled	R/W
b31 to b6	—	Reserved	When writing, write 0.	R/W

31.3.2.8 FRINDEX Register

Address(es) A004 102Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	Frame Index[13:0]													
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b13 to b0	Frame Index[13:0]	Frame index	These bits are used by the host logic to add an index to the periodic frame list. This value is incremented at the end of each micro-frame. Bits [N:3] are used as the Frame List Current index. This means that the current frame list is accessed 8 times before proceeding with the next index number. The value of N is determined as follows according to the setting of bits [3:2] (Frame List Size) in the USBCMD register. **Frame List Size / Number Elements / N** 00 (1024) 12 01 (512) 11 10 (256) 10 11 Reserved This register should be accessed only while the host logic is stopped (bit 12 (HCHalted) = 1 in the USBSTS register). This setting is reflected in the SOF frame number for the SOF token.	R/W
b31 to b14	—	Reserved	When writing, write 0.	R/W

31.3.2.9 CTRLDSSEGMENT Register

Address(es) A004 1030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CTRLDSSEGMENT[31:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CTRLDSSEGMENT[31:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CTRLDSSEGMENT[31:0]	—	The host logic does not support 64-bit addressing and does not use this register. Therefore, do not access this register.	R

31.3.2.10 PERIODICLISTBASE Register

Address(es) A004 1034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	BaseAddress (Low) [21:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BaseAddress (Low) [21:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	—	Reserved	When writing, write 0.	R/W
b31 to b12	BaseAddress (Low) [21:0]	Periodic frame list start address	These bits indicate the start address of the periodic frame list stored in the system memory. Software should specify the start address in this register before the host logic starts list processing. The host logic uses the values in these bits and bits [13:0] (Frame Index) in the FRINDEX register to determine the frame list to be processed. The address of the periodic frame list should be aligned with a 4-Kbyte boundary. Correct operation cannot be guaranteed if the value in these bits is modified during operation.	R/W

31.3.2.11 ASYNCLISTADDR Register

Address(es) A004 1038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	LPL[26:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LPL[26:0]											—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	—	Reserved	When writing, write 0.	R/W
b31 to b5	LPL[26:0] (Link Pointer Low)	Asynchronous Queue Head link pointer address	These bits indicate the address of the next asynchronous queue head in the system memory to be processed. The address of the asynchronous queue head should be aligned with a 32-byte boundary.	R/W

31.3.2.12 CONFIGFLAG Register

Address(es) A004 1060h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	CF
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CF (Configure Flag)	Port routing control circuit configuration flag	This bit controls the default setting of the port routing control circuit regarding whether the ports are routed to OHCI or EHCI. Software should set this bit to 1 at the end of host logic configuration process. 0: Port routing control circuit routes each port to the OHCI host logic by default. 1: Port routing control circuit routes each port to the EHCI host logic by default.	R/W
b31 to b1	—	Reserved	When writing, write 0.	R/W

31.3.2.13 PORTSC1 Register

Address(es) A004 1064h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	WKOC_E	WKDSCNNT_E	WKCNNT_E	Port Test Control [3:0]			
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Port Indicator Control[1:0]		Port Owner	PP	Line Status[1:0]		—	Port Reset	Suspend	Force Port Resume	Over-current Change	Over-current Active	Port Enable/ Disable Change	Port Enabled/ Disabled	Connect Status Change	Current Connect Status
Value after reset	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	Current Connect Status	Port connection status	This bit indicates the connection state of the port. Upon detecting device connection, the host logic sets this bit to 1. The host logic also sets this bit to 1 when Port Test Control[3:0] = 0101b (Test FORCE_ENABLE) even if no device is connected. Upon detecting device disconnection, the host logic clears this bit to 0. When the PP bit is 0 or the Port Owner bit is 0, this bit becomes 0. 0: No device is connected to the port. 1: Device is connected to the port.	R
b1	Connect Status Change	Connect status change	This bit indicates that the value of bit 0 (Current Connect Status) has changed. Writing 1 can clear this bit. Writing 0 has no effect. When the PP bit is 0, this bit becomes 0. 0: Nothing is to be done. 1: Value of bit 0 (Current Connect Status) has changed.	R/W
b2	Port Enabled/ Disabled	Port enable/disable status	This bit indicates the enabled/disabled state of the port. After resetting a port and detecting that the connected device is an HS device, the host logic enables the port and sets this bit to 1. Software cannot set this bit to 1. Upon detecting device disconnection or an error, the host logic disables the port and clears this bit to 0. Software can write 0 to disable the port. In this case, however, the bit value changes only after the port state actually changes. While the port is disabled, data transfer to downstream ports is blocked except for a port reset. When the PP bit is 0, this bit becomes 0. Note that when Port Test Control[3:0] = 0101b (Test FORCE_ENABLE), the port is enabled regardless of the port state and this bit is set to 1. 0: Port is disabled. 1: Port is enabled.	R/W
b3	Port Enable/ Disable Change	Port enable/disable status change	This bit indicates that the enabled/disabled state of the port has changed. Upon detecting a frame babble error, the host logic disables the port and sets this bit to 1. Writing 1 can clear this bit. Writing 0 has no effect. When the PP bit is 0, this bit becomes 0. 0: Nothing is to be done. 1: The port state has changed from enabled to disabled.	R/W
b4	Over-current Active	Port overcurrent status	This bit indicates the overcurrent state of the port. Upon detecting an overcurrent, the host logic clears bit 12 (PP) and its related bits and sets this bit to 1b. This bit is automatically cleared from 1 to 0 when the overcurrent state is resolved. 0: Port is not in overcurrent state. 1: Port is in overcurrent state.	R

Bit	Symbol	Bit Name	Description	R/W
b5	Over-current Change	Over-current Change	This bit indicates that the value of bit 4 (Over-current Active) has changed. Writing 1 can clear this bit. Writing 0 has no effect. 0: Nothing is to be done. 1: Value of bit 4 (Over-current Active) has changed.	R/W
b6	Force Port Resume	Port resume detection flag	This bit indicates detection of the resume state at the port. When a transition from the J to the K state (RemoteWakeup) is detected while the port is suspended, the host logic sets this bit and bit 2 (Port Change Detect) in the USBSTS register to 1. Software should also set this bit to 1 when the output of a resume signal is required. In this case, the Port Change Detect bit should not be set. The resume signal (FS K State) is driven on the USB port while this bit is 1. Clear this bit to 0 after an appropriate period has passed. Writing 0 to this bit while it is 1 returns the port to the HS Idle state. Until then, this bit remains at 1. When the PP bit is 0, this bit becomes 0. 0: Resume (K-state) has not been detected or output. 1: Resume (K-state) has been detected or output.	R/W
b7	Suspend	Port suspend	This bit indicates the suspend state of the port. 0: Port is not in suspend state. 1: Port is in suspend state. The combination of the settings of this bit and bit 2 (Port Enabled/Disabled) indicate the port state as follows. **Port Enabled/Disabled / Suspend / Port State** 0 / X / Disabled 1 / 0 / Enabled 1 / 1 / Suspend In the suspend state, data transfer from this port to the downstream port is blocked unless the port is reset. When this bit is set to 1 during data transfer, reflection in the status bit and blocking of transfer follow completion of the current transfer. Software should write 1 to this bit. It can write 1 only while PP bit = 1, Port Owner bit = 0, and Current Connect Status bit = 1 in the register in the host logic. This bit is always cleared to 0 under either of the following conditions. • Software clears the Force Port Resume bit to 0. • Software sets the Port Reset bit to 1. When the PP bit is 0, this bit becomes 0.	R/W
b8	Port Reset	Port reset status	This bit indicates the reset state of the port. 0: Port is not in reset state. 1: Port is in reset state. When software writes 1 to this bit while it is 0, the bus reset sequence defined in the USB2.0 standard begins. Write 0 to this bit to terminate the bus reset sequence. Note that this bit must be retained at 1 for long enough time for the bus reset sequence to be completed according to the USB2.0 standard. When bit 12 (HCHalted) in the USBSTS register is 1, the port should not be reset. This bit becomes 0 when the PP, Port Owner, or Current Connect Status bit satisfies the following conditions. • PP bit = 0, • Port Owner bit = 1, or • Current Connect Status bit = 0	R/W
b9	—	Reserved	When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b11, b10	Line Status[1:0]	D+/D- logic level	These bits indicate the current logical levels on the D+ and D- lines of the USB port (bit 11: D+; bit 10: D-). They are used to detect an LS device before a port reset or a sequence for enabling the port. Therefore, the values in these bits are valid only while bit 3 (Port Enable/Disable) = 0 and bit 0 (Current Connect Status) = 1. When the PP bit is 0, these bits become 0.	R

bit11 (D+)	bit10 (D-)	USB State	Interpretation
0	0	SE0	Not an LS device. Moves to the EHCI port reset execution process.
0	1	K State	An LS device has been connected. Passes the port ownership from EHCI to OHCI.
1	0	J State	Not an LS device. Moves to the EHCI port reset execution process.
1	1	Un-defined	Not an LS device. Moves to the EHCI port reset execution process.

Bit	Symbol	Bit Name	Description	R/W
b12	PP (Port Power)	Port power supply control	This bit controls power supply to the port. When this bit is 0, power is not supplied to the port; the port does not operate and connection or disconnection cannot be detected. If an overcurrent is detected while this bit is 1, the host logic clears this bit to 0 and stops power supply to the port. 0: No power is supplied to the port. 1: Power is supplied to the port. The function of this bit depends on the setting of bit 4 (PPC) in the HCSPARAMS register.	R/W

PPC	PP	Description
0	1	This bit is fixed to 1, and power is always supplied to the port.
1	0/1	Power supply to the port is determined by this bit.

Bit	Symbol	Bit Name	Description	R/W
b13	Port Owner	Port ownership	This bit indicates whether OHCI or EHCI has the port ownership. 0: EHCI has the port ownership. 1: OHCI has the port ownership. This bit is cleared to 0 when bit 0 (CF) in the CONFIGFLAG register changes from 0 to 1. This bit is set to 1 when the CF bit is 0. Software should set this bit to 1 to pass the port ownership to OHCI when the connected device is not a high-speed device.	R/W
b15, b14	Port Indicator Control[1:0]	—	As the host logic does not support the port indicator control function, these bits are set to 00b. Writing to these bits does not affect the operation.	R
b19 to b16	Port Test Control[3:0]	Pin test control	These bits control the test mode. For details of the test mode, see Chapter 7 in the USB Specification Revision 2.0.	R/W

Port Test Control[3:0]	Mode
0000b	Normal
0001b	Test J_STATE
0010b	Test K_STATE
0011b	Test SE0_NAK
0100b	Test Packet
0101b	Test FORCE_ENABLE
Other than the above	Reserved

Bit	Symbol	Bit Name	Description	R/W
b20	WKCNNT_E (Wake on Connect Enable)	Device connection detection enable	Writing 1 to this bit enables detection of device connection as a wakeup event. This bit setting does not affect the host logic operation. When the PP bit is 0, this bit becomes 0.	R/W
b21	WKDSCNNT_E (Wake on Disconnect Enable)	Device disconnection detection enable	Writing 1 to this bit enables detection of device disconnection as a wakeup event. This bit setting does not affect the host logic operation. When the PP bit is 0, this bit becomes 0.	R/W
b22	WKOC_E (Wake on Over-current Enable)	Overcurrent state detection enable	Writing 1 to this bit enables detection of the overcurrent state as a wakeup event. This bit setting does not affect the host logic operation. When the PP bit is 0, this bit becomes 0.	R/W
b31 to b23	—	Reserved	When writing, write 0.	R/W

31.3.3 PCI Configuration Registers for OHCI

31.3.3.1 Offset 00h Register (Vendor ID, Device ID)

Address(es) A005 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Device ID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	1	1	0	1	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Vendor ID[15:0]															
Value after reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	Vendor ID [15:0]	Device vendor ID	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R
b31 to b16	Device ID [15:0]	Device ID	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R

31.3.3.2 Offset 04h Register (Command, Status)

Address(es) A005 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Detected Parity Error	Signaled System Error	Received Master Abort	Received Target Abort	Signaled Target Abort	Devsel Timing[1:0]		Data Parity Error Detected	Fast Back to Back Capable	—	—	Capabilities List	—	—	—	—
Value after reset	0	0	0	0	0	0	1	0	0	0	0	1	0	0	0	0

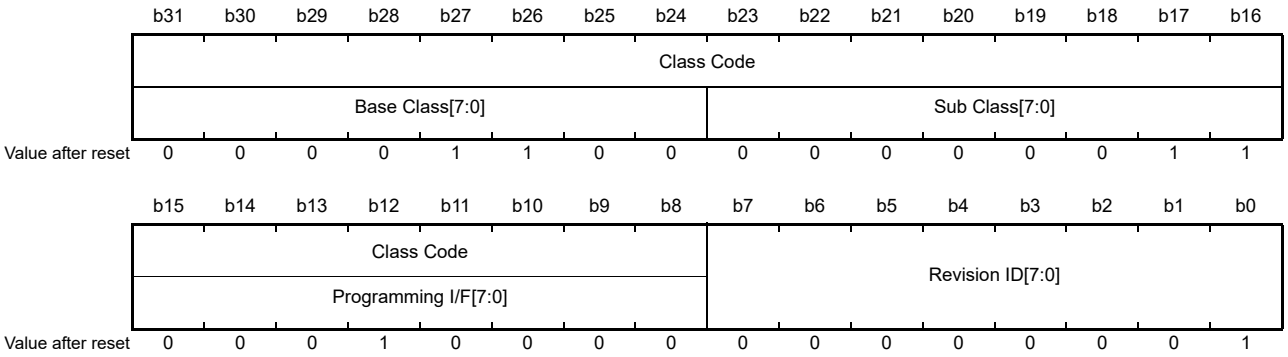
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	Fast Back to Back Enable	SERR Enable	Wait Cycle Control	Parity Error Response	VGA Palette Snoop	Memory Write and Invalidate Enable	Special Cycle	Bus Master	Memory Space	I/O Space
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	I/O Space	I/O space access enable	This bit enables access to the I/O space. As the host logic does not accept I/O access, this value is always 0.	R
b1	Memory Space	Memory space access enable	This bit enables access to the memory space. This is an enable signal for memory access specified in the PCI standard. Set to 1 when accessing registers. Set this bit to 1 during initial setting of the host logic.	R/W
b2	Bus Master	Bus master enable	This bit enables bus master operation. This is an enable signal for master access to the PCI bus. Set to 1 when accessing the SRAM on the system bus. Set this bit to 1 during initial setting of the host logic.	R/W
b3	Special Cycle	Special cycle enable	This bit enables Special Cycle operation. As the host logic does not support the Special Cycle operation, this value is always 0.	R
b4	Memory Write and Invalidate Enable	Memory write and invalidate enable	This bit enables the Memory Write and Invalidate command. In the USB host controller, do not change this from the value after reset (0). 0: Memory write and invalidate command is disabled. 1: Memory write and invalidate command is enabled.	R/W
b5	VGA Palette Snoop	VGA palette snoop enable	This bit enables VGA palette snooping. As the host logic does not support VGA palette snooping, this value is always 0.	R
b6	Parity Error Response	Parity error response enable	This bit enables parity error response. 0: PERR0 is not asserted. 1: PERR0 is asserted. When a parity error is detected, the Detected Parity Error bit is set to 1 even if this bit is cleared to 0.	R/W
b7	Wait Cycle Control	Wait cycle control enable	This bit enables wait cycle control. As the host logic does not support address and data stepping, this value is always 0.	R
b8	SERR Enable	System error response enable	This bit enables system error response. 0: SERR0 is not asserted. 1: SERR0 is asserted. To notify of a system error through the SERR signal, set this bit to 1.	R/W
b9	Fast Back to Back Enable	Fast back to back enable	This bit enables fast back to back transactions. As the host logic does not support fast back to back transactions, this value is always 0.	R
b19 to b10	—	Reserved	When writing, write 0.	R/W
b20	Capabilities List	Power management mode support	This value is fixed to 1, which indicates that the power management mode is supported.	R
b22, b21	—	Reserved	When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b23	Fast Back to BackCapable	Fast back to back support	This bit indicates whether Fast Back to Back transactions are supported. As the host logic does not support Fast Back to Back transactions, this value is fixed to 0.	R
b24	Data Parity Error Detected	Data parity error detection flag	This bit is set when a parity error is detected in master operation. Writing 1 from the PCI bus clears this bit. The value is fixed to 0 while the Parity Error Response bit is set as disabled.	R/W
b26, b25	Devsel Timing[1:0]	DEVSEL response speed	These bits indicate the DEVSEL response speed. The value is fixed to 01b (medium-speed response).	R
b27	Signaled Target Abort	Slave/Target abort status	This is a status bit for Slave/Target abort. This bit is set to 1 in slave operation when the host logic has terminated, through Target Abort, the bus cycle in which the host logic is accessed. Writing 1 from the PCI bus clears this bit.	R/W
b28	Received Target Abort	Master/Target abort status	This is a status bit for Master/Target Abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Target Abort. Writing 1 from the PCI bus clears this bit.	R/W
b29	Received Master Abort	Master/Master abort status	This is a status bit for Master/Master Abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Master Abort. Writing 1 from the PCI bus clears this bit.	R/W
b30	Signaled System Error	SERR status	This is a status bit for SERR. This bit is set to 1 when a system error occurs. Writing 1 from the PCI bus clears this bit.	R/W
b31	Detected Parity Error	Parity error status	This is a status bit for parity error. This bit is set when an address or data parity error is detected. Writing 1 from the PCI bus clears this bit.	R/W

31.3.3.3 Offset 08h Register (Revision ID, Class Code)

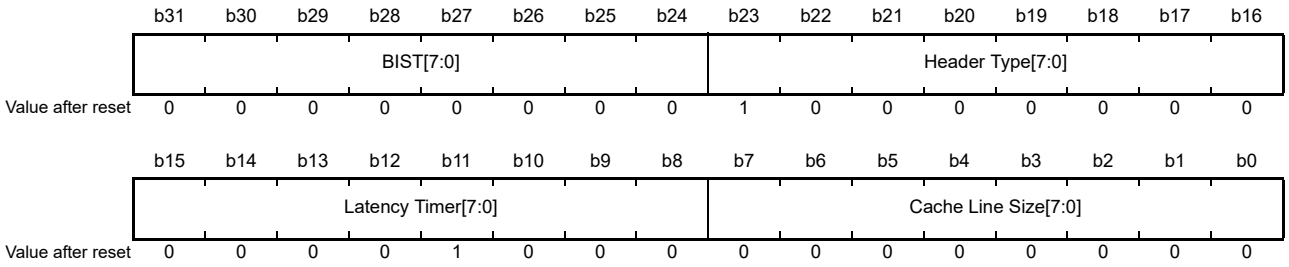
Address(es) A005 0008h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Revision ID [7:0]	Host logic revision	These bits indicate the revision of the host logic. The value is indicated as 01h.	R
b15 to b8	Programming I/F[7:0]	PCI standard program interface	These bits indicate the program interface specified in the PCI standard. The value is 10h, which indicates OHCI.	R
b23 to b16	Sub Class [7:0]	PCI standard subclass	These bits indicate the subclass specified in the PCI standard. The value is 03h, which indicates a USB device.	R
b31 to b24	Base Class [7:0]	PCI standard base class	These bits indicate the base class specified in the PCI standard. The value is 0Ch, which indicates a serial peripheral bus controller.	R

31.3.3.4 Offset 0Ch Register (Cache Line Size, Latency Timer, Header Type, BIST)

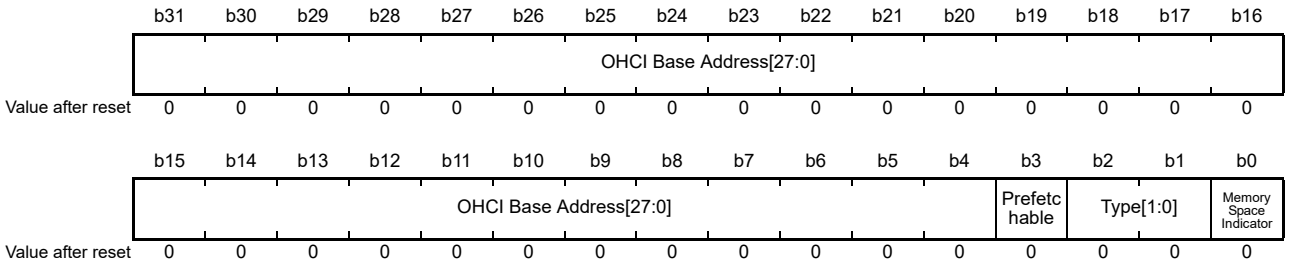
Address(es) A005 000Ch



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Cache Line Size[7:0]	Cache Line Size	These bits notify the system of the cache line size.	R/W
b9, b8	Latency Timer[7:0]	Latency Timer	These bits notify the system of the latency timer. The lowest 2 bits are fixed to 00b.	R
b15 to b10				R/W
b23 to b16	Header Type[7:0]	Header Type	These bits notify the system of the header type. As the header type is Type 0, bits [22:16] are fixed to 00h. As this is a multifunction device, bit 23 is fixed to 1.	R
b31 to b24	BIST[7:0]	Self-test	These bits are used for self testing. As the host logic does not support the self test function, this value is always 00h.	R

31.3.3.5 Offset 10h Register (OHCI Base Address)

Address(es) A005 0010h



Bit	Symbol	Bit Name	Description	R/W
b0	Memory Space Indicator	Memory space indicator	This bit is fixed to 0, which indicates that the OHCI operational registers are mapped to the system memory space.	R
b2, b1	Type[1:0]	Base address type	These bits are fixed to 00b, which indicates that the base address of the OHCI operational registers has a 32-bit width and can be allocated to any location in a 32-bit memory space.	R
b3	Prefetchable	Prefetch setting	As the host logic does not support prefetching in memory read cycles, this bit is fixed to 0.	R
b11 to b4	OHCI Base Address [27:0]	OHCI base address	Bits [31:12] specify the base address of the operational registers. Specify the base address of the operational registers determined by the system during initialization. Bits [11:4] are fixed to 00h, which indicates that the operational registers are allocated to a 4-Kbyte address space.	R
b31 to b12				R/W

31.3.3.6 Offset 2Ch Register (Subsystem Vendor ID, Subsystem ID)

Address(es) A005 002Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Subsystem ID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	1	1	0	1	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Subsystem Vendor ID[15:0]															
Value after reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	Subsystem Vendor ID [15:0]	Subsystem vendor ID	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R
b31 to b16	Subsystem ID[15:0]	Subsystem ID	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R

31.3.3.7 Offset 30h Register (Expansion ROM Base Address)

Address(es) A005 0030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Expansion ROM Base Address[21:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Expansion ROM Base Address[21:0]						—	—	—	—	—	—	—	—	—	ROM Decode Enable
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ROM Decode Enable	Expansion ROM decode enable	As decoding of expansion ROM is prohibited, this bit is always read as 0. This bit cannot be written to.	R
b9 to b1	—	Reserved	Don't care	R
b31 to b10	Expansion ROM Base Address[21:0]	Expansion ROM base address	As decoding of expansion ROM is prohibited, these bits are always read as 000000h. These bits cannot be written to.	R

31.3.3.8 Offset 34h Register (Capability Pointer)

Address(es) A005 0034h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	Capability Pointer[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Capability Pointer[7:0]	Capability identifier pointer	These bits hold the pointer to the capability identifier. As the pointer is set to 40h in the host logic, this value is set to 40h.	R
b31 to b8	—	Reserved	Don't care	R

31.3.3.9 Offset 3Ch Register (Interrupt Line, Interrupt Pin, Min gnt, Max Latency)

Address(es) A005 003Ch

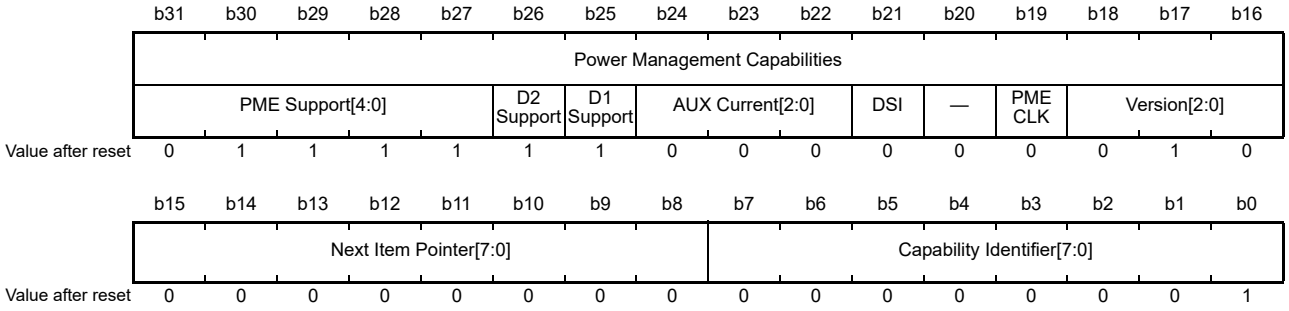
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Max Latency[7:0]								Min Gnt[7:0]							
Value after reset	0	0	1	0	1	0	1	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Interrupt Pin[7:0]								Interrupt Line[7:0]							
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Interrupt Line [7:0]	Interrupt line	These bits indicate the interrupt line. In the USB host controller, do not change this from the value after reset (00h).	R/W
b15 to b8	Interrupt Pin [7:0]	Interrupt output pin	These bits indicate the pin for outputting interrupts. As INTA is used, this value is fixed to 01h.	R
b23 to b16	Min Gnt[7:0]	Minimum burst transfer time	These bits indicate the minimum burst transfer time. As the minimum time is set to 01h in the host logic, this value is set to 01	R
b31 to b24	Max Latency[7:0]	Maximum frequency of PCI bus acquisition	These bits indicate the maximum frequency of PCI bus acquisition. As the maximum frequency is set to 2Ah in the host logic, this value is set to 2Ah.	R

31.3.3.10 Offset 40h Register (Capability Identifier, Next Item Pointer, Power Management Capabilities)

Address(es) A005 0040h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Capability Identifier [7:0]	PCI power management register ID	These bits indicate the PCI power management register ID. The value is fixed to 01h.	R
b15 to b8	Next Item Pointer[7:0]	Next item non-existence	These bits are fixed to 00h, which indicates that the next item does not exist.	R
b18 to b16	Version[2:0]	Version	These bits are fixed to 010b, which indicates that the host logic conforms to the PCI Power Management Interface Specification Release 1.1.	R
b19	PME CLK	USBPCLK unnecessary	This bit is fixed to 0, which indicates that USBPCLK is not required for PME interrupt generation.	R
b20	—	Reserved	Don't care	R
b21	DSI	Power management initialization unnecessary	This bit is fixed to 0, which indicates that special initialization is not required for power management.	R
b24 to b22	Aux Current[2:0]	Current setting value	These bits indicate the necessary current for 3.3-V auxiliary power supply. As PME interrupt generation from the D3 cold state is not supported, this value is fixed to 000b.	R
b25	D1 Support	PCI power state D1 support	This bit is fixed to 1, which indicates that PCI power state D1 is supported.	R
b26	D2 Support	PCI power state D2 support	This bit is fixed to 1, which indicates that PCI power state D2 is supported.	R
b30 to b27	PME Support[4:0]	PME interrupt support	These bits are fixed to 1111b, which indicates that PME interrupt generation is supported in all PCI power states (D0 to D3).	R
b31		D3 cold state support	This bit indicates whether the D3 cold state is supported. As the D3 cold state is not supported, this value is fixed to 0.	R

31.3.3.11 Offset 44h Register (Power Management Control/Status, PMCSR Bridge Support Extensions)

Address(es) A005 0044h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Data								PMCSR Bridge Support Extensions							
	Data[7:0]								BPCC Enable	B2_B3	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Power Management Control/Status															
	PME Status	Data Scale[1:0]		Data Select[3:0]				PME Enable	—	—	—	—	—	—	Power State[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	Power State[1:0]	PCI power status	These bits indicate the power state of the PCI as follows. b1 b0 0 0: D0 State 0 1: D1 State 1 0: D2 State 1 1: D3 hot State	R/W
b7 to b2	—	Reserved	When writing, write 0.	R/W
b8	PME Enable	PME enable	This bit specifies whether to use PME. Setting this bit to 1 generates a PME interrupt when operation returns from the power management state.	R/W
b12 to b9	Data Select[3:0]	Data selection field	The value of these bits is 0h. This is an optional field in the PCI standard, and the host logic does not support it.	R
b14, b13	Data Scale[1:0]	Data scale field	The value of these bits is 00b. This is an optional field in the PCI standard, and the host logic does not support it.	R
b15	PME Status	PME interrupt status	This bit indicates the PME interrupt state. It is set to 1 when the following condition for PME generation is satisfied. [PME generation condition] Bit 3 (RD) in the HcInterruptStatus register is set to 1 while bit 10 (RWE) in the HcControl register is 1. Writing 1 from the PCI bus clears this bit to 0.	R/W
b21 to b16	—	Reserved	When writing, write 0.	R/W
b22	B2_B3	Bit for bridge	The value of this bit is 0. This is a bit for the bridge, and the host logic does not support it.	R
b23	BPCC Enable	BPCC enable	The value of this bit is 0. This is a bit for the bridge, and the host logic does not support it.	R
b31 to b24	Data[7:0]	Data field	The value of these bits is 00h. This is an optional field in the PCI standard, and the host logic does not support it.	R

31.3.3.12 Offset E0h Register (EXT1)

This register is the same as the EXT1 register located in the EHCI configuration space.
Therefore, this register can be accessed also by using the offset address on the EHCI configuration register side.

Address(es) A005 00E0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	potpgt								Hyper Speed transfer Control #2					—	—	—
Value after reset	0	0	0	0	1	1	1	1	0	0	0	1	0	1	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	Hyper Speed transfer Control #1	PSD	—	—	—	—	ID_Write _Enable	—	—	—	—	—	Port_no	
Value after reset	0	0	1	1	0	0	1	1	0	0	0	1	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	Port_no	USB downstream port number	These bits specify the number of valid USB downstream ports. **Setting Value** / **Valid Ports** 01b / Port1 10b / Port1 and Port2 Other than the above / Reserved In the USB host controller, do not change this from the value after reset (1h).	R/W
b6 to b2	—	Reserved	Do not change this from the value after reset.	R/W
b7	ID_Write _Enable	Write-protect control	This bit write-protects the Subsystem ID, Subsystem Vendor ID, Max Latency, and Min Gnt bits. 0: Write-protected 1: Can be written to.	R/W
b11 to b8	—	Reserved	Do not change this from the value after reset.	R/W
b12	PSD	Periodic schedule disable	0: For transferring data via USB while the USBCMD.Periodic Schedule Enable bit is being 0, always set this bit to 0. 1: No settings required (initial value) Setting this bit is arbitrary when the USBCMD.Periodic Schedule Enable bit is 1.	R/W
b13	Hyper Speed transfer Control #1 (HS Async OUT advance Mode)	Hyper-speed transfer mode setting	This bit specifies the hyper-speed transfer mode for asynchronous OUT transfer. Setting to 1 enables this function (transfer rate improvement).	R/W
b18 to b14	—	Reserved	Do not change this from the value after reset.	R/W
b23 to b19	Hyper Speed transfer Control #2	HS asynchronous FIFO threshold setting field	Do not specify any value other than 02h (HS asynchronous FIFO threshold = 64 bytes).	R/W
b31 to b24	Potpgt	POTPGT setting field	These bits specify the value for bits [31:24] (PPOTPGT) in the OHCI HcRhDescriptorA register. POTPGT is the time that software should wait before accessing a root hub port after power supply to the port is started.	R/W

31.3.3.13 Offset E4h Register (EXT2)

This register is the same as the EXT2 register located in the EHCI configuration space.
Therefore, this register can be accessed also by using the offset address on the EHCI configuration register side.
However, note that bit 0 (EHCI_mask) can be written to only on the OHCI side.

Address(es) A005 00E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	RAM Connect Check Result	RAM Connect Check END Flag	RUN RAM Connect Check
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	Hyper Speed transfer Control #3	EHCI_mask
Value after reset	0	1	1	0	1	1	0	0	0	0	0	0	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	EHCI_mask	EHCI host logic mask	This bit enables or disables the EHCI host logic. 0: EHCI host logic is enabled. 1: EHCI host logic is disabled. When this bit is set to 1, register access in the EHCI PCI configuration space and memory space is disabled and the EHCI host logic does not operate.	R/W
b1	Hyper Speed transfer Control #3	Hyper-speed transfer mode setting	This bit specifies the hyper-speed transfer mode for asynchronous IN/OUT transfer. Setting to 1 enables this function (transfer rate improvement).	R/W
b15 to b2	—	Reserved	Do not change this from the value after reset.	R/W
b16	RUN RAM Connect Check	RAM connection check circuit activation	This bit activates the RAM connection check circuit. Set this bit to 1 to start the RAM connection check. This bit is not cleared even after the check is completed. To check again, write 0 to this bit to clear it, and then write 1 again to start the check. When this bit changes from 0 to 1, the connection check circuit is reset and the RAM Connect Check END Flag bit and RAM Connect Check Result bit are cleared.	R/W
b17	RAM Connect Check END Flag	RAM connection check end flag	This bit indicates the end of RAM connection check. 0: Connection check has not been done or ended. 1: Connection check has ended. This bit is set when a specified time (about 2 µs) has passed after the RAM connection check is started by modifying the RUN RAM check bit from 0 to 1.	R
b18	RAM Connect Check Result	RAM connection check result	This bit indicates the result of RAM connection check. 0: Connection check result is NG. 1: Connection check result is OK. This value is valid when the RAM Connect Check END Flag bit is 1. Once the connection check is done, this value is not cleared until the RUN RAM Connect Check bit changes from 0 to 1.	R
b31 to b19	—	Reserved	Do not change this from the value after reset.	R/W

31.3.4 PCI Configuration Registers for EHCI

31.3.4.1 Offset 00h Register (Vendor ID, Device ID)

Address(es) A005 0100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Device ID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	1	1	1	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Vendor ID[15:0]															
Value after reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	Vendor ID [15:0]	Vendor ID	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R
b31 to b16	Device ID [15:0]	Device ID	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R

31.3.4.2 Offset 04h Register (Command, Status)

Address(es) A005 0104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Detected Parity Error	Signaled System Error	Received Master Abort	Received Target Abort	Signaled Target Abort	Devsel Timing[1:0]		Data Parity Error Detected	Fast Back to Back Capable	—	Capable 66MHz	Capabilities List	—	—	—	—
Value after reset	0	0	0	0	0	0	1	0	0	0	0	1	0	0	0	0

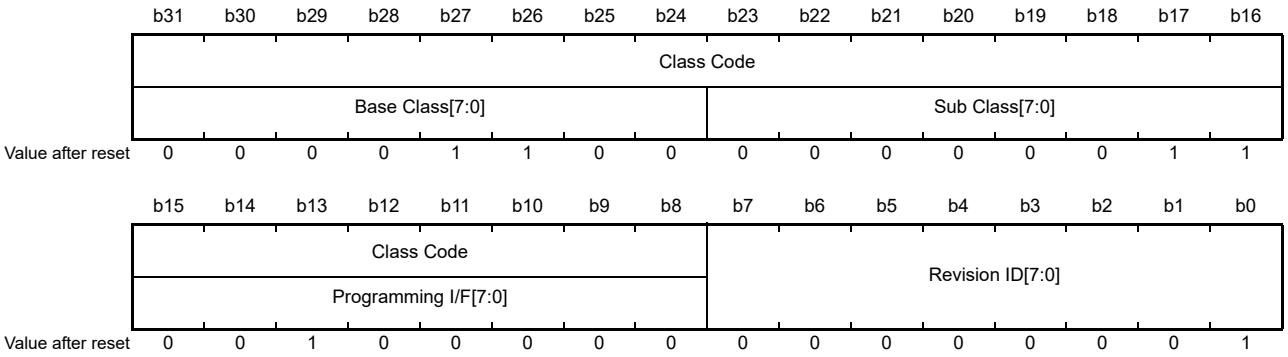
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	Fast Back to Back Enable	SERR Enable	Wait Cycle Control	Parity Error Response	VGA Palette Snoop	Memory Write and Invalidate Enable	Special Cycle	Bus Master	Memory Space	I/O Space
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	I/O Space	I/O space access enable	This bit enables access to the I/O space. As the host logic does not accept I/O access, this value is always 0.	R
b1	Memory Space	Memory space access enable	This bit enables access to the memory space. This is an enable signal for memory access specified in the PCI standard. Set to 1 when accessing registers. Set this bit to 1 during initial setting of the host logic.	R/W
b2	Bus Master	Bus master enable	This bit enables bus master operation. This is an enable signal for master access to the PCI bus. Set to 1 when accessing the SRAM on the system bus. Set this bit to 1 during initial setting of the host logic.	R/W
b3	Special Cycle	Special cycle enable	This bit enables special cycle operation. As the host logic does not support the special cycle operation, this value is always 0.	R
b4	Memory Write and Invalidate Enable	Memory write and invalidate enable	This bit enables the Memory Write and Invalidate command. In the USB host controller, do not change this from the value after reset (0). 0: Memory write and invalidate command is disabled. 1: Memory write and invalidate command is enabled.	R/W
b5	VGA Palette Snoop	VGA palette snoop enable	This bit enables VGA palette snooping. As the host logic does not support VGA palette snooping, this value is always 0.	R
b6	Parity Error Response	Parity error response enable	This bit enables parity error response. 0: PERR0 is not asserted. 1: PERR0 is asserted. When a parity error is detected, the Detected Parity Error bit is set to 1 even if this bit is cleared to 0.	R/W
b7	Wait Cycle Control	Wait cycle control enable	This bit enables wait cycle control. As the host logic does not support address and data stepping, this value is always 0.	R
b8	SERR Enable	System error response enable	This bit enables system error response. 0: SERR0 is not asserted. 1: SERR0 is asserted. To notify of a system error through the SERR signal, set this bit to 1.	R/W
b9	Fast Back to Back Enable	Fast back to back enable	This bit enables fast back to back transactions. As the host logic does not support fast back to back transactions, this value is always 0.	R
b19 to b10	—	Reserved	When writing, write 0.	R/W
b20	Capabilities List	Power management mode support	This value is fixed to 1, which indicates that the power management mode is supported.	R

Bit	Symbol	Bit Name	Description	R/W
b21	Capable 66MHz	66-MHz operation capable	This bit indicates whether 66-MHz operation is available. As the host logic operates only at 33 MHz, this value is fixed to 0.	R
b22	—	Reserved	When writing, write 0.	R/W
b23	Fast Back to Back Capable	Fast back to back capable	This bit indicates whether fast back to back transactions are supported. As the host logic does not support fast back to back transactions, this value is fixed to 0.	R
b24	Data Parity Error Detected	Parity error detection	This bit is set when a parity error is detected in master operation. Writing 1 from the PCI bus clears this bit. The value is fixed to 0 when the Parity Error Response bit is set as disabled.	R/W
b26, b25	Devsel Timing[1:0]	DEVSEL response speed bit field	These bits indicate the DEVSEL response speed. The value is fixed to 01b (medium-speed response).	R
b27	Signaled Target Abort	Slave/Target abort status	This is a status bit for Slave/Target abort. This bit is set to 1 in slave operation when the host logic has terminated the bus cycle in which the host logic is accessed through Target Abort. Writing 1 from the PCI bus clears this bit.	R/W
b28	Received Target Abort	Master/Target abort status	This is a status bit for Master/Target abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Target Abort. Writing 1 from the PCI bus clears this bit.	R/W
b29	Received Master Abort	Master/Master abort status	This is a status bit for Master/Master abort. This bit is set to 1 in master operation when the bus cycle being executed by the host logic is terminated through Master Abort. Writing 1 from the PCI bus clears this bit.	R/W
b30	Signaled System Error	SERR status	This is a status bit for SERR. This bit is set when a system error occurs. Writing 1 from the PCI bus clears this bit.	R/W
b31	Detected Parity Error	Parity error status	This is a status bit for parity error. This bit is set when an address or data parity error is detected. Writing 1 from the PCI bus clears this bit.	R/W

31.3.4.3 Offset 08h Register (Revision ID, Class Code)

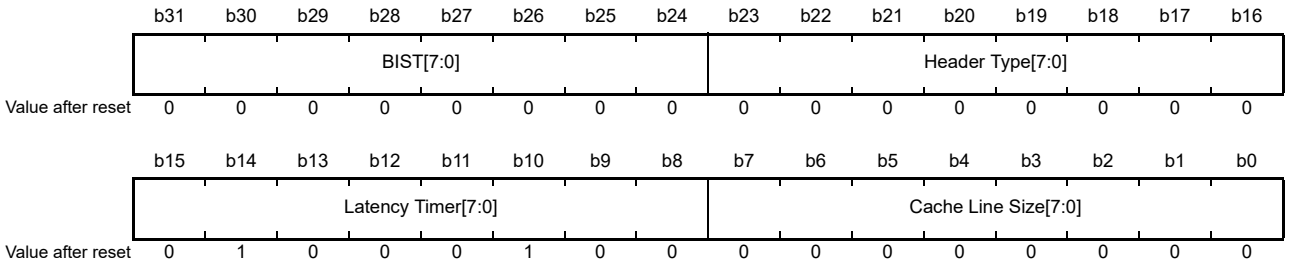
Address(es) A005 0108h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Revision ID [7:0]	Host logic revision	These bits indicate the revision of the host logic. The value is fixed to 01h.	R
b15 to b8	Programming I/F[7:0]	PCI standard program interface bit field	These bits indicate the program interface specified in the PCI standard. The value is 20h, which indicates EHCI.	R
b23 to b16	Sub Class [7:0]	PCI standard subclass	These bits indicate the subclass specified in the PCI standard. The value is 03h, which indicates a USB device.	R
b31 to b24	Base Class [7:0]	PCI standard base class	These bits indicate the base class specified in the PCI standard. The value is 0Ch, which indicates a serial peripheral bus controller.	R

31.3.4.4 Offset 0Ch Register (Cache Line Size, Latency Timer, Header Type, BIST)

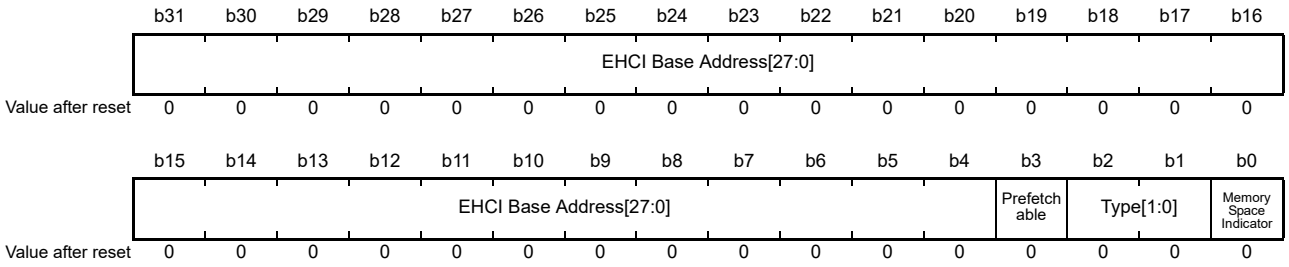
Address(es) A005 010Ch



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Cache Line Size[7:0]	Cache line size	These bits notify the system of the cache line size.	R/W
b9, b8	Latency Timer[7:0]	Latency timer	These bits notify the system of the latency timer. The lowest 2 bits are fixed to 00b.	R
b15 to b10				R/W
b23 to b16	Header Type [7:0]	Header type	These bits notify the system of the header type. As the header type is Type 0, bits [22:16] are fixed to 00h. As the multifunction capability is not supported, bit 23 is fixed to 0.	R
b31 to b24	BIST[7:0]	Self testing field	These bits are used for self testing. As the host logic does not support the self test function, this value is always 00h.	R

31.3.4.5 Offset 10h Register (EHCI Base Address)

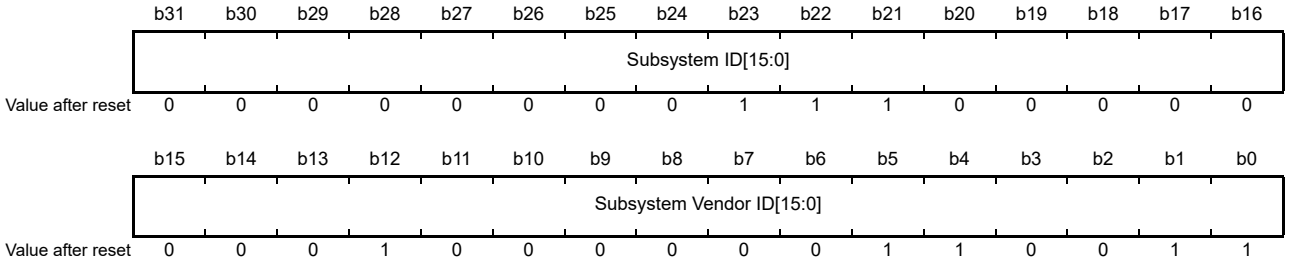
Address(es) A005 0110h



Bit	Symbol	Bit Name	Description	R/W
b0	Memory Space Indicator	System memory space indicator	This bit is fixed to 0, which indicates that the EHCI operational registers are mapped to the system memory space.	R
b2, b1	Type[1:0]	Base address allocation type	These bits are fixed to 00b, which indicates that the base address of the EHCI operational registers has a 32-bit width and can be allocated to any location in a 32-bit memory space.	R
b3	Prefetchable	Prefetch support	As the host logic does not support prefetching in memory read cycles, this bit is fixed to 0.	R
b7 to b4	EHCI Base Address [27:0]	EHCI base address	Bits [31:8] specify the base address of the operational registers. Specify the base address of the operational registers determined by the system during initialization. Bits [7:4] are fixed to 0h, which indicates that the operational registers are allocated to a 256-byte address space.	R
b31 to b8				R/W

31.3.4.6 Offset 2Ch Register (Subsystem Vendor ID, Subsystem ID)

Address(es) A005 012Ch



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	Subsystem Vendor ID [15:0]	Subsystem vendor ID	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R
b31 to b16	Subsystem ID [15:0]	Subsystem ID	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R

31.3.4.7 Offset 30h Register (Expansion ROM Base Address)

Address(es) A005 0130h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Expansion ROM Base Address[21:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Expansion ROM Base Address[21:0]						—	—	—	—	—	—	—	—	—	ROM Decode Enable
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ROM Decode Enable	ROM decode enable	As decoding of expansion ROM is prohibited, this bit is always read as 0. This bit cannot be written to.	R
b9 to b1	—	Reserved	Don't care	R
b31 to b10	Expansion ROM Base Address[21:0]	Expansion ROM base address	As decoding of expansion ROM is prohibited, these bits are always read as 000000h. These bits cannot be written to.	R

31.3.4.8 Offset 34h Register (Capability Pointer)

Address(es) A005 0134h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	Capability Pointer[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Capability Pointer[7:0]	Capability identifier pointer	These bits hold the pointer to the capability identifier. As the pointer is set to 40h in the host logic, this value is set to 40h.	R
b31 to b8	—	Reserved	Don't care	R

31.3.4.9 Offset 3Ch Register (Interrupt Line, Interrupt Pin, Min gnt, Max Latency)

Address(es) A005 013Ch

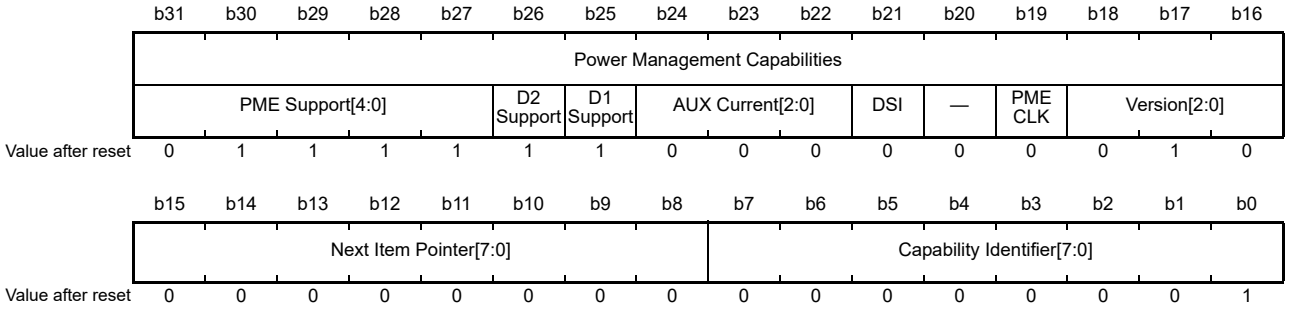
	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Max Latency[7:0]								Min Gnt[7:0]							
Value after reset	0	0	1	0	0	0	1	0	0	0	0	1	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Interrupt Pin[7:0]								Interrupt Line[7:0]							
Value after reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Interrupt Line [7:0]	Interrupt line	These bits indicate the interrupt line. In the USB host controller, do not change this from the value after reset (00h).	R/W
b15 to b8	Interrupt Pin [7:0]	Interrupt output pin	These bits indicate the pin for outputting interrupts. As INTB is used, this value is fixed to 02h.	R
b23 to b16	Min Gnt[7:0]	Minimum burst transfer time	These bits indicate the minimum burst transfer time. As the minimum time is set to 10h in the host logic, this value is 10h.	R
b31 to b24	Max Latency [7:0]	PCI bus maximum acquisition frequency	These bits indicate the maximum frequency of PCI bus acquisition. As the maximum frequency is set to 22h in the host logic, this value is set to 22h.	R

31.3.4.10 Offset 40h Register (Capability Identifier, Next Item Pointer, Power Management Capabilities)

Address(es) A005 0140h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	Capability Identifier [7:0]	Power management register ID	These bits indicate the power management register ID. The value is fixed to 01h.	R
b15 to b8	Next Item Pointer[7:0]	Next item pointer	These bits are fixed to 00h, which indicates that the next item does not exist.	R
b18 to b16	Version[2:0]	PCI version	These bits are fixed to 010b, which indicates that the host logic conforms to the PCI Power Management Interface Specification Release 1.1.	R
b19	PME CLK	USBPCLKPCLK necessity	This bit is fixed to 0, which indicates that USBPCLKPCLK is not necessary for PME interrupt generation.	R
b20	—	Reserved	—	R
b21	DSI	Special initialization necessity	This bit is fixed to 0, which indicates that special initialization is not necessary for power management.	R
b24 to b22	Aux Current [2:0]	Current setting value	These bits indicate the required current for 3.3-V auxiliary power supply. As PME interrupt generation from the D3 cold state is not supported, this value is fixed to 000b.	R
b25	D1 Support	PCI power state D1 support	This bit is fixed to 1, which indicates that PCI power state D1 is supported.	R
b26	D2 Support	PCI power state D2 support	This bit is fixed to 1, which indicates that PCI power state D2 is supported.	R
b30 to b27	PME Support [4:0]	PME interrupt support bit field	These bits are fixed to 1111b, which indicates that PME interrupt generation is supported in all PCI power states (D0 to D3).	R
b31		D3 cold state support	This bit indicates whether the D3 cold state is supported. As the D3 cold state is not supported, this value is fixed to 0.	R

31.3.4.11 Offset 44h Register (Power Management Control/Status, PMCSR Bridge Support Extensions)

Address(es) A005 0144h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	Data								PMCSR Bridge Support Extensions							
	Data[7:0]								BPCC Enable	B2_B3	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	Power Management Control/Status															
	PME Status	Data Scale[1:0]		Data Select[3:0]				PME Enable	—	—	—	—	—	—	Power State[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	Power State [1:0]	PCI power status	These bits indicate the power state of the PCI as follows. b1 b0 0 0: D0 State 0 1: D1 State 1 0: D2 State 1 1: D3 hot State	R/W
b7 to b2	—	Reserved	When writing, write 0.	R/W
b8	PME Enable	PME enable	This bit specifies whether to use external pin PME. Setting this bit to 1 generates a PME interrupt when operation returns from the power management state.	R/W
b12 to b9	Data Select [3:0]	Data selection field	The value of these bits is 0h. This is an optional field in the PCI standard, and the host logic does not support it.	R
b14, b13	Data Scale [1:0]	Data scale field	The value of these bits is 00b. This is an optional field in the PCI standard, and the host logic does not support it.	R
b15	PME Status	PME interrupt status	This bit indicates the PME interrupt state. It is set to 1 when the PME generation condition is satisfied. Writing 1 from the PCI bus clears this bit to 0.	R/W
b21 to b16	—	Reserved	When writing, write 0.	R/W
b22	B2_B3	Bridge	The value of this bit is 0. This is a bit for the bridge and the host logic does not support it.	R
b23	BPCC Enable	BPCC enable	The value of this bit is 0. This is a bit for the bridge and the host logic does not support it.	R
b31 to b24	Data[7:0]	PCI standard option field	The value of these bits is 00h. This is an optional field in the PCI standard, and the host logic does not support it.	R

31.3.4.12 Offset 60h Register (SBRN, FLADJ, PORTWAKECAP)

Address(es) A005 0160h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PORTWAKECAP[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	FLADJ[7:0]								SBRN[7:0]							
Value after reset	0	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SBRN[7:0]	Serial bus release number	These bits indicate the serial bus release number. The value is fixed to 20h.	R
b13 to b8	FLADJ[7:0]	1 micro frame length	These bits adjust the length of a micro-frame in 16-HS bit time units. The value after reset is 20h (60000d HS bit time).	R/W
b15, b14				R
b31 to b16	PORTWAKECAP[15:0]	Wakeup event mask field	From among the connected devices, these bits specify a mask for which port to be used in response to a wakeup event. This setting does not affect the actual operation of the host logic. The USB host controller only has one port so this register never needs be used.	R/W

31.3.4.13 Offset E0h Register (EXT1)

This register is the same as the EXT1 register located in the OHCI configuration space. See the description of the OHCI configuration register.

31.3.4.14 Offset E4h Register (EXT2)

This register is the same as the EXT2 register located in the OHCI configuration space. See the description of the OHCI configuration register.

Note that bit 0 (EHCI_mask) cannot be accessed from the EHCI side.

31.3.5 PCI Configuration Register for AHB-PCI Bridge

31.3.5.1 Offset 00h Register (Vendor ID, Device ID)

Address(es) A005 0000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DEVICE_ID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	VENDOR_ID[15:0]															
Value after reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	VENDOR_ID [15:0]	Vendor ID	This register indicates the vendor of the device. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host. It is always read as 1033h.	R
b31 to b16	DEVICE_ID [15:0]	Device ID	This register indicates the device type. This is used to select a driver that operates the device as specified in the PCI standard. This register does not need to be used in the embedded host.	R

31.3.5.2 Offset 04h Register (Command, Status)

Address(es) A005 0004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	DETPERR	SIGSERR	REMABORT	RETABORT	SIGTABORT	DEVTIM[1:0]		MDPERR	FBTBCAP	—	CAP66M	CAPLIST	—	—	—	—
Value after reset	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0

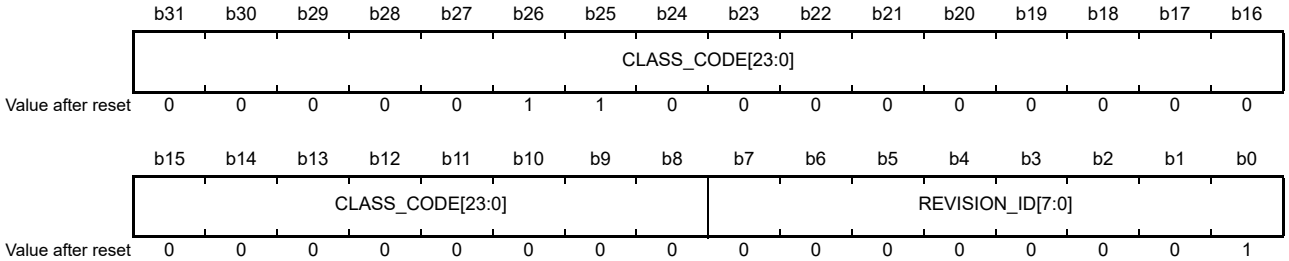
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	FBTBEN	SERREN	STEPCTR	PERREN	VGAPSNP	MWINVEN	SPECIALC	MASTEREN	MEMEN	IOEN
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	IOEN	I/O space access enable	This bit enables access to the I/O space. The value is fixed to 0.	R
b1	MEMEN	PCI slave operation setting	This bit specifies the PCI slave operation. In the USB host controller, set this bit to 1 during the initial settings. 0: Memory cycles cannot be accepted (value after reset) 1: Memory cycles can be accepted.	R/W
b2	MASTEREN	PCI master operation setting	This bit specifies the PCI master operation. In the USB host controller, set this bit to 1 during the initial settings. 0: Master operation is disabled (value after reset). 1: Master operation is enabled.	R/W
b3	SPECIALC	Special cycle enable	This bit enables the special cycle operation. The value is fixed to 0.	R
b4	MWINVEN	Memory write and invalidate enable	This bit enables the Memory Write and Invalidate command. The value is fixed to 0.	R
b5	VGAPSNP	VGA palette snoop enable	This bit enables VGA palette snooping. The value is fixed to 0.	R
b6	PERREN	Parity error detection operation setting	This bit specifies the operation when a parity error is detected. In the USB host controller, set this bit to 1 during the initial settings. 0: Nothing is to be done. (value after reset) 1: PERR# is asserted.	R/W
b7	STEPCTR	Address stepping control	This bit controls address stepping. The value is fixed to 0. (Address stepping is not done.)	R
b8	SERREN	System error detection operation setting	This bit specifies the operation when a system error is detected. In the USB host controller, set this bit to 1 during the initial settings. 0: Nothing is to be done. (value after reset) 1: SERR# is asserted.	R/W
b9	FBTBEN	Fast back to back enable	This bit enables fast back to back transactions. The value is fixed to 0.	R
b19 to b10	—	Reserved	When writing, write 0.	R/W
b20	CAPLIST	Capabilities list support	This bit indicates whether the capabilities list is supported. The value is fixed to 0. (The capabilities list is not supported.)	R
b21	CAP66M	66-MHz operation support	This bit indicates whether 66-MHz operation is supported. The value is fixed to 0. (66-MHz operation is not supported.)	R
b22	—	Reserved	When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b23	FBTBCAP	Fast back to back capability	This bit indicates whether fast back to back transactions are supported. The value is fixed to 0. (Fast back to back transactions are not supported.)	R
b24	MDPERR	Parity error detection flag	This bit is set when a parity error is detected in master operation. Writing 1 clears this bit. 0: Parity error has not been detected. 1: Parity error has been detected.	R/W
b26, b25	DEVTIM[1:0]	DEVSEL response speed	These bits indicate the DEVSEL response speed. The value is fixed to 01b (Medium Mode).	R
b27	SIGTABORT	Slave Target Abort status	This is a status bit for Slave Target Abort. This bit is set when Target Abort is transmitted. Writing 1 clears this bit. 0: Target Abort has not been transmitted. 1: Target Abort has been transmitted.	R/W
b28	RETABORT	Master Target Abort status	This is a status bit for Master Target Abort. This bit is set when Target Abort is received. Writing 1 clears this bit. 0: Target Abort has not been received. 1: Target Abort has been received.	R/W
b29	REMABORT	Master Abort status	This is a status bit for Master Abort. This bit is set when Master Abort is received. Writing 1 clears this bit. 0: Master Abort has not been received. 1: Master Abort has been received.	R/W
b30	SIGSERR	SERR status	This is a status bit for SERR. This bit is set when a system error occurs. Writing 1 clears this bit. 0: SERR# has not been asserted. 1: SERR# has been asserted.	R/W
b31	DETPERR	Parity error status	This is a status bit for parity error. This bit is set when an address or data parity error is detected. Writing 1 clears this bit. 0: Parity error has not been detected. 1: Parity error has been detected.	R/W

31.3.5.3 Offset 08h Register (Revision ID, Class Code)

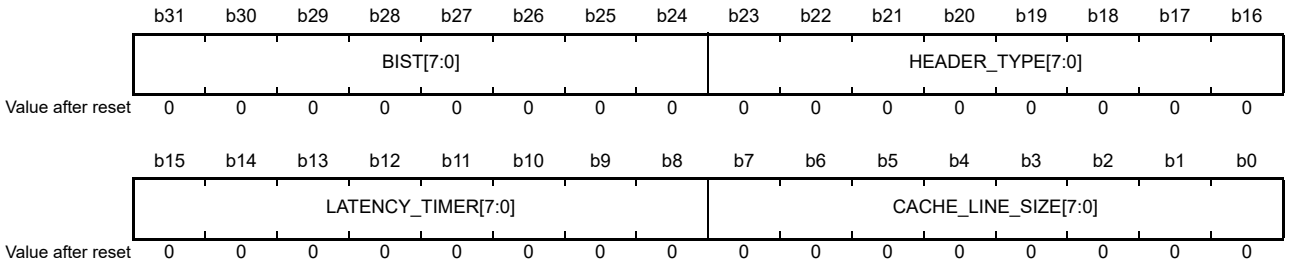
Address(es) A005 0008h



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	REVISION_ID[7:0]	Revision ID	The value of these bits is 01h.	R
b31 to b8	CLASS_CODE[23:0]	CLASS CODE	The value of these bits is 060000h.	R

31.3.5.4 Offset 0Ch Register (Cache Line Size, Latency Timer, Header Type, BIST)

Address(es) A005 000Ch



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CACHE_LINE_SIZE[7:0]	CACHE LINE SIZE	The value of these bits is 00h (cache is not supported).	R
b15 to b8	LATENCY_TIMER[7:0]	Latency timer	These bits notify the system of the latency timer. The USB host controller does not use the latency timer; do not change this from the value after reset (00h).	R/W
b23 to b16	HEADER_TYPE[7:0]	HEADER TYPE	The value of these bits is 00h (single function device).	R
b31 to b24	BIST[7:0]	BIST	The value of these bits is 00h (BIST is not implemented).	R

31.3.5.5 Offset 10h Register (AHB-PCI Bridge Base Address)

Address(es) A005 0010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PCICOM_BASEADR[21:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	PCICOM_BASEADR[21:0]						—	—	—	—	—	—	PREFETCH	TYPE[1:0]		MEM
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MEM	Base address specifying memory space	This bit indicates that the bits specified by the base address are in the memory space. The value is fixed to 0.	R
b2, b1	TYPE[1:0]	Base address type	These bits indicate the base address type. The value is 00b. (The base address can be allocated to any location in a 4-Gbyte space.)	R
b3	PREFETCH	Data prefetch capability	This bit indicates whether data can be prefetched. The value is fixed to 0. (Data cannot be prefetched.)	R
b9 to b4	—	Reserved	When writing, write 0.	R/W
b31 to b10	PCICOM_BASEADR[21:0]	AHB-PCI bridge PCI communication register area base address	These bits specify the base address of the AHB-PCI bridge PCI communication register area. A 1-Kbyte area is necessary and the 24 high-order bits specify the base address.	R/W

31.3.5.6 Offset 14h Register (PCI-AHB WIN1 Base Address)

Address(es) A005 0014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PCI_WIN1_BASEADR [3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PREFETCH	TYPE[1:0]		MEM
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MEM	Base address specifying memory space	This bit indicates that the field specified by the base address is in the memory space. The value is fixed to 0.	R
b2, b1	TYPE[1:0]	Base address type	These bits indicate the base address type. The value is 00b. (The base address can be allocated to any location in a 4-Gbyte space.)	R
b3	PREFETCH	Data prefetch capability	This bit indicates whether data can be prefetched. The value is fixed to 1. (Data can be prefetched.)	R
b27 to b4	—	Reserved	When writing, write 0.	R/W
b31 to b28	PCI_WIN1_ BASEADR[3:0]	PCI-AHB Window1 base address	These bits specify the base address of PCI-AHB Window 1. For the PCI-AHB Window 1 space, a 1-Gbyte area can be accessed through the setting of bits [11:10] (PCI_AHB_WIN1_SIZE) in the USBCTR register. **PCI-AHB Window 1 Space** / **AHB_BASEADR[31:28]** 1 Gbyte: The 2 higher-order bits [31:30] are the base address. Other bits are masked by 0. For details of register setting, see section 31.4.1, Register Access.	R/W

31.3.5.7 Offset 2Ch Register (Subsystem Vendor ID, Subsystem ID)

Address(es) A005 002Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	SUBSYS_ID[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SUBSYS_VENDOR_ID[15:0]															
Value after reset	0	0	0	1	0	0	0	0	0	0	1	1	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	SUBSYS_ VENDOR_ID [15:0]	Subsystem vendor ID	The value of these bits is 1033h.	R
b31 to b16	SUBSYS_ID [15:0]	Subsystem ID	The value of these bits is 0000h.	R

31.3.5.8 Offset 3Ch Register (Interrupt Line, Interrupt Pin, Min gnt, Max Latency)

Address(es) A005 003Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	MAX_LAT[7:0]								MIN_GNT[7:0]							
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	INT_PIN[7:0]								INT_LINE[7:0]							
Value after reset	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	INT_LINE[7:0]	Interrupt line	These bits specify the interrupt line. In the USB host controller, do not change this from the value after reset (00h).	R
b15 to b8	INT_PIN[7:0]	Interrupt pin field	The value of these bits is 01h. (INTA# is used).	R
b23 to b16	MIN_GNT[7:0]	Latency timer request field	The value of these bits is 02h. (Requested latency timer: 16 burst).	R
b31 to b24	MAX_LAT[7:0]	Bus use frequency request field	The value of these bits is 00h. (No value is specified for the bus use frequency.)	R

31.3.6 AHB-PCI Bridge PCI Communication Registers

31.3.6.1 PCIAHB_WIN1_CTR Register

This register is used to make settings for access from the host logic to AHB.

Address(es) A005 0800h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AHB_BASEADR[3:0]				—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PREFETCH[1:0]	
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	PREFETCH [1:0]	AHB bus prefetch setting bit field	These bits specify whether to prefetch data in the AHB bus when the host logic issues a read request. In the USB host controller, set these bits to 11b during the initial settings and do not change the value. b1 b0 0 0: Prefetch is disabled. 0 1: Prefetch is enabled (up to 4 bursts). 1 0: Prefetch is enabled (up to 8 bursts). 1 1: Prefetch is enabled (up to 16 bursts).	R/W
b27 to b2	—	Reserved	When writing, write 0.	R/W
b31 to b28	AHB_BASEADR [3:0]	AHB bus base address	These bits specify the base address of the AHB bus for access from the host logic to PCI-AHB Window 1. For the PCI-AHB Window 1 space, a 1-Gbyte area can be made accessible through the setting of bits [11:10] (PCI_AHB_WIN1_SIZE) in the USBCTR register. Do not modify this value from the value after reset (0000b). **PCI-AHB Window 1 Space** / **AHB_BASEADR[31:28]** 1 Gbyte: The 2 high-order bits (bits [31:30]) specify the base address. For details of register setting, see section 31.4.1, Register Access.	R/W

31.3.6.2 AHBPCI_WIN1_CTR Register

This register is used to make necessary settings for access to the PCI configuration space.

Address(es) A005 0810h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	PCIWIN1_BASEADR[20:0]					—	—	—	—	—	—	—	PCICMD[2:0]			—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	When writing, write 0.	R/W
b3 to b1	PCICMD[2:0]	PCI bus cycle type	These bits specify the type of PCI bus cycle. In the USB host controller, set these bits to 101b during the initial settings and do not change the value. b3 b1 000: Interrupt Acknowledge / Special Cycle 001: IO Read / IO Write 011: Memory Read / Memory Write 101: Configuration Read / Configuration Write 110: Memory Read Multiple / Memory Write 111: Memory Read Line / Memory Write Setting is prohibited for other than the above.	R/W
b10 to b4	—	Reserved	When writing, write 0.	R/W
b31 to b11	PCIWIN1_BASEADR [20:0]	PCI bus base address	These bits specify the base address of the PCI bus for access from AHB to AHB-PCI Window 1. This register should be set when the PCI configuration space for the host logic or for the AHB-PCI bridge is accessed. For details of settings, see section 31.4.1.1, Access to PCI Configuration Registers.	R/W

31.3.6.3 AHBPCI_WIN2_CTR Register

This register is used to make necessary settings for access to the OHCI operational register area.

Address(es) A005 0814h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	PCIWIN2_BASEADR[15:0]															
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	—	—	BURST_EN	—	PCICMD[2:0]			—
Value after reset	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	When writing, write 0.	R/W
b3 to b1	PCICMD[2:0]	PCI bus cycle type	These bits specify the type of PCI bus cycle. In the USB host controller, set these bits to 011b during the initial settings and do not change the value. b3 b1 001: IO Read / IO Write 011: Memory Read / Memory Write 110: Memory Read Multiple / Memory Write 111: Memory Read Line / Memory Write Setting is prohibited for other than the above.	R/W
b4	—	Reserved	When writing, write 0.	R/W
b5	BURST_EN	PCI bus burst transfer enable	This bit enables burst transfer to the PCI bus. In the USB host controller, clear to 0 during the initial settings and do not change the value. 0: Burst transfer is disabled. 1: Burst transfer is enabled.	R/W
b15 to b6	—	Reserved	When writing, write 0.	R/W
b31 to b16	PCIWIN2_BASEADR[15:0]	PCI bus base address	These bits specify the base address of the PCI bus for access from AHB to AHB-PCI Window 2. This register is used for access to the OHCI operational register area. For details of settings, see section 31.4.1.1, Access to PCI Configuration Registers.	R/W

31.3.6.4 PCI_INT_ENABLE Register

This register enables or disables each interrupt source indicated in the PCI_INT_STATUS register. When an interrupt source is disabled, the interrupt signal is not asserted even when the interrupt source is generated and the corresponding bit in the PCI_INT_STATUS register is set to 1.

Address(es) A005 0820h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SIGTABORT_INTEN	SIGTABORT interrupt enable	This bit enables or disables the interrupt source indicated in bit 0 (SIGTABORT_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b1	RETABORT_INTEN	RETABORT interrupt enable	This bit enables or disables the interrupt source indicated in bit 1 (RETABORT_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b2	REMABORT_INTEN	REMABORT interrupt enable	This bit enables or disables the interrupt source indicated in bit 2 (REMABORT_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b3	PERR_INTEN	PERR interrupt enable	This bit enables or disables the interrupt source indicated in bit 3 (PERR_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b4	SIGSERR_INTEN	SIGSERR interrupt enable	This bit enables or disables the interrupt source indicated in bit 4 (SIGSERR_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b5	RESERR_INTEN	RESERR interrupt enable	This bit enables or disables the interrupt source indicated in bit 5 (RESERR_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b11 to b6	—	Reserved	When writing, write 0.	R/W
b12	PCIAHB_WIN1_INTEN	PCIAHB_WIN1 interrupt enable	This bit enables or disables the interrupt source indicated in bit 12 (PCIAHB_WIN1_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b13	PCIAHB_WIN2_INTEN	PCIAHB_WIN2 interrupt enable	This bit enables or disables the interrupt source indicated in bit 13 (PCIAHB_WIN2_INT) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b15, b14	—	Reserved	When writing, write 0.	R/W
b16	USBH_INTAEN	USBH interrupt enable	This bit enables or disables the interrupt source indicated in bit 16 (USBH_INTA) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b17	USBH_ INTBEN	USBH interrupt enable	This bit enables or disables the interrupt source indicated in bit 17 (USBH_INTB) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b18	—	Reserved	When writing, write 0.	R/W
b19	USBH_ PMEEN	USBH_PME enable	This bit enables or disables the interrupt source indicated in bit 19 (USBH_PME) in PCI_INT_STATUS. 0: Disabled 1: Enabled	R/W
b31 to b20	—	Reserved	When writing, write 0.	R/W

31.3.6.5 PCI_INT_STATUS Register

This register indicates the state of interrupt sources in the AHB-PCI bridge and the state of interrupt signals from the host logic.

Address(es) A005 0824h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	USBH_PME	—	USBH_INTB	USBH_INTA
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	PCIAHB_WIN2_INT	PCIAHB_WIN1_INT	—	—	—	—	—	—	RESERR_INT	SIGSERR_INT	PERR_INT	REMABORT_INT	RETABORT_INT	SIGTABORT_INT
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SIGTABORT_INT	Target Abort notification	This bit indicates that Target Abort has been sent in PCI target operation. Writing 1 clears this bit. 0: Target Abort has not been sent. 1: Target Abort has been sent.	R/W
b1	RETABORT_INT	Target Abort reception	This bit indicates that Target Abort has been received in PCI master operation. Writing 1 clears this bit. 0: Target Abort has not been received. 1: Target Abort has been received.	R/W
b2	REMABORT_INT	MasterAbort reception	This bit indicates that Master Abort has been received in PCI master operation. Writing 1 clears this bit. 0: Master Abort has not been received. 1: Master Abort has been received.	R/W
b3	PERR_INT	PERR# Input/Output interrupt source status	This bit indicates the state of the interrupt source caused by PERR# input/output. Writing 1 clears this bit. 0: PERR# has not been asserted. 1: PERR# has been asserted.	R/W
b4	SIGSERR_INT	SERR# Output interrupt source status	This bit indicates the state of the interrupt source caused by SERR# output. Writing 1 clears this bit. 0: SERR# has not been asserted. 1: SERR# has been asserted.	R/W
b5	RESERR_INT	SERR# Input interrupt source status	This bit indicates the state of the interrupt source caused by SERR# input. Writing 1 clears this bit. 0: SERR# assertion has not been detected. 1: SERR# assertion has been detected.	R/W
b11 to b6	—	Reserved	When writing, write 0.	R/W
b12	PCIAHB_WIN1_INT	AHB bus error occurrence flag	This bit indicates that an AHB bus error has occurred in PCIAHB Window 1. Writing 1 clears this bit. 0: AHB bus error has not occurred. 1: AHB bus error has occurred.	R/W
b13	PCIAHB_WIN2_INT	AHB bus error occurrence flag	This bit indicates that an AHB bus error has occurred in PCIAHB Window 2. Writing 1 clears this bit. 0: AHB bus error has not occurred. 1: AHB bus error has occurred.	R/W
b15, b14	—	Reserved	When writing, write 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b16	USBH_INTA	Host logic INTA# interrupt status	This bit indicates the state of the INTA# interrupt from the host logic. The interrupt can be cleared from the host logic. 0: INTA interrupt has not occurred. 1: INTA interrupt has occurred.	R
b17	USBH_INTB	Host logic INTB# interrupt status	This bit indicates the state of the INTB# interrupt from the host logic. The interrupt can be cleared from the host logic. 0: INTB interrupt has not occurred. 1: INTB interrupt has occurred.	R
b18	—	Reserved	When writing, write 0.	R/W
b19	USBH_PME	Host logic PME# interrupt status	This bit indicates the state of the PME# interrupt from the host logic. The interrupt can be cleared from the host logic. 0: PME interrupt has not occurred. 1: PME interrupt has occurred.	R
b31 to b20	—	Reserved	When writing, write 0.	R/W

31.3.6.6 AHB_BUS_CTR Register

This register specifies the AHB master and slave functions of the host logic.

Address(es) A005 0830h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	SMODE_READY_CTR	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	MMODE_HBUSREQ	—	—	—	—	MMODE_WR_INCR	MMODE_BYTE_BURST	MMODE_HTRANS
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MMODE_HTRANS	HTRANS signal operation mode setting	This bit specifies the operating mode for the HTRANS signal in AHB master operation. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: For divided cycles, NONSEQ is output continuously. 1: For divided cycles, IDLE is inserted and the bus is requested again through HBUSREQ.	R/W
b1	MMODE_BYTE_BURST	Burst transfer control	This bit controls burst transfer for 16-bit or 8-bit transfer in AHB master operation. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: Burst transfer is enabled for 16-bit or 8-bit transfer. 1: Burst transfer is disabled for 16-bit or 8-bit transfer.	R/W
b2	MMODE_WR_INCR	Condition setting of using undefined-length burst transfer	This bit specifies the condition of using an undefined-length burst for write transfer in AHB master operation. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: INCR is always used except when the transfer count is 4, 8, or 16. 1: INCR4, INCR8, and INCR16 are generally used, and INCR is used only when the remaining data is 2 to 3 beats.	R/W
b6 to b3	—	Reserved	When writing, write 0.	R/W
b7	MMODE_HBUSREQ	HBUSREQ deassertion timing setting	This bit specifies the timing of HBUSREQ deassertion in AHB master operation. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: Deasserted in the last address phase of the cycle. 1: Deasserted with the first timing of HGRANT = 1 and HREADY = 1.	R/W
b16 to b8	—	Reserved	When writing, write 0.	R/W
b17	SMODE_READY_CTR	Wait operation control	This bit controls the wait operation in AHB slave operation. Set this bit to 0 in a system that uses RETRY or SPLIT. Do not modify this value except for initial setting. 0: Wait is controlled with HRESP = RETRY. 1: Wait is controlled with HREADY = 0.	R/W
b31 to b18	—	Reserved	When writing, write 0.	R/W

31.3.6.7 USBCTR Register

This register is used to make settings of the host logic.

Address(es) A005 0834h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	PCI_AHB_WIN1_SIZE[1:0]		PCI_AHB_WIN2_EN	—	—	—	—	—	—	—	PCICLK_MASK	USBH_RST
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	USBH_RST	Reset signal control	This bit controls the reset signal supplied to the host logic. The host logic can be accessed a maximum of 3 USBPCLK clock cycles after the reset is canceled. 0: Host logic reset is canceled. 1: Host logic reset is issued.	R/W
b1	PCICLK_MASK	PCI clock supply mask	This bit stops the PCI clock supply in the host logic. Note that the host logic cannot be accessed when this bit is set to 1. 0: PCI clock is supplied. 1: PCI clock is stopped.	R/W
b8 to b2	—	Reserved	When writing, write 0.	R/W
b9	PCI_AHB_WIN2_EN	PCI-AHB Window2 enable	This bit enables operation of PCI-AHB Window 2. For details, see section 31.4.1, Register Access. 0: PCI-AHB Window 2 is not available. Settings other than the above are prohibited. Operation cannot be guaranteed if the setting of this bit is modified.	R/W
b11, b10	PCI_AHB_WIN1_SIZE[1:0]	PCI-AHB Window1 area	These bits control the PCI-AHB Window 1 area. For details, see section 31.4.1, Register Access. Do not modify this value except for initial setting. b11 b10 10: 1 Gbyte	R/W
b31 to b12	—	Reserved	When writing, write 0.	R/W

31.3.6.8 PCI_ARBITER_CTR Register

This register is used to make settings of the PCI bus arbitration function.

Address(es) A005 0840h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	PCIBP_MODE	—	—	—	—	—	—	—	—	—	—	PCIREQ1	PCIREQ0
Value after reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PCIREQ0	PCI bus request signal mask 0	This bit enables or disables the PCI bus request signal from this unit. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: Request signal is disabled. 1: Request signal is enabled.	R/W
b1	PCIREQ1	PCI bus request signal mask 1	This bit enables or disables the PCI bus request signal from the host logic. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: Request signal is disabled. 1: Request signal is enabled.	R/W
b11 to b2	—	Reserved	When writing, always write 0.	R/W
b12	PCIBP_MODE	Master setting	This bit specifies the master while the PCI bus is in the parked state. In the USB host controller, set this bit to 1 during the initial settings and do not change the value. 0: This unit is the master in the bus-parked state. 1: The master that made the last access is the master in the bus-parked state.	R/W
b31 to b13	—	Reserved	Do not change this from the value after reset.	R/W

31.3.6.9 PCI_UNIT_REV Register

This register indicates the version of the AHB-PCI bridge macro.

Address(es) A005 0848h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	Minor Revision ID [15:0]	Minor revision ID	These bits indicate the minor revision ID of this unit.	R
b31 to b16	Major Revision ID [15:0]	Major revision ID	These bits indicate the major revision ID of this unit.	R

31.4 Register Access

31.4.1 Register Access

Registers are accessed through the internal PCI bus. To access them from the AHB bus correctly, appropriately specify the mapping between the memory space for the AHB bus and that for the internal PCI bus in the USB host controller (see section 31.8.1.1, Sample of Initial Settings). Note that the PCI space is divided into two: the PCI memory space where data transfer is actually done, and the PCI configuration space where PCI bus transfer settings and the settings of the base addresses in the PCI memory space are stored.

Access from the AHB to the host logic and master access from the host logic to the AHB are done through the window areas in the AHB-PCI bridge. Figure 31.3 and Table 31.5 show the functions and relationship of register and window areas.

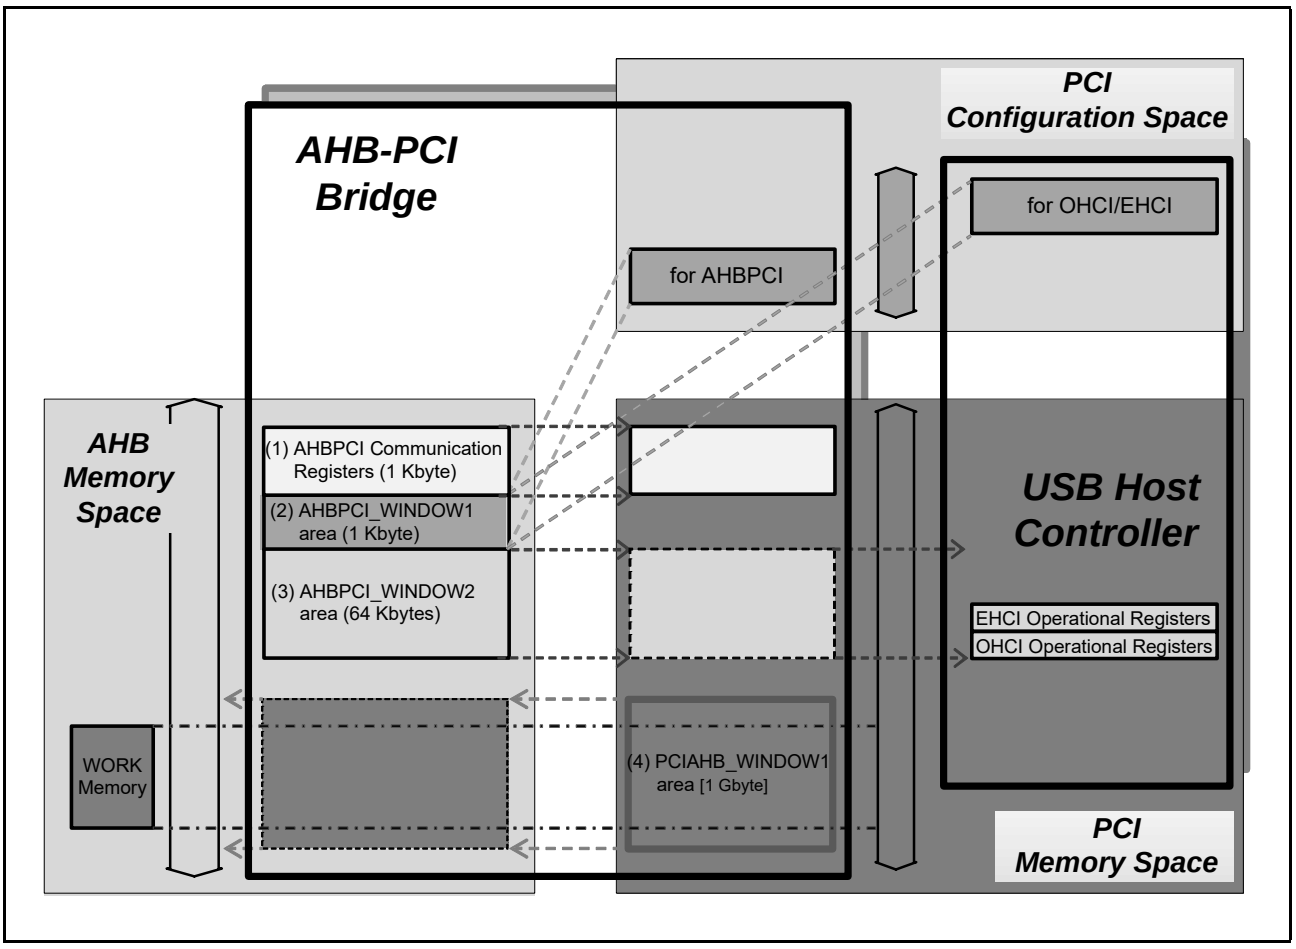

Figure 31.3 Image of AHB and PCI Space Mapping

Table 31.5 Descriptions of Areas

AHB Area Name	Size	Description
(1) AHBPCI communication registers	1 Kbyte	Various AHB settings are stored and the base address of each window area is specified. This area is also allocated in the PCI memory space; make sure that it does not overlap with other areas.
(2) AHBPCI_WINDOW1 area	1 Kbyte	The PCI configuration registers are accessed through this area. Whether to access an OHCI/EHCI configuration register or a register in the AHB-PCI bridge is switched through the AHBPCI_WIN1_CTR register setting.
(3) AHBPCI_WINDOW2 area	64 Kbytes	The OHCI/EHCI operational registers are accessed through this area.
(4) PCIAHB_WINDOW1 area	1 Gbyte	The host logic accesses the work memory on the AHB bus through this area. The size can be selected through the USBCTR register.

Make sure that the AHBPCI communication registers and the AHB-PCI window 2 area (OHCI/EHCI operational registers) do not overlap with the PCIAHB window 1 area in the PCI memory space.
An easy way to do this is to allocate the areas to the same addresses in both the AHB memory space and the PCI memory space.
However, when the above areas overlap due to the memory map for the AHB bus, use the PCI configuration registers (OHCI/EHCI/AHB-PCI Base Address registers) to avoid overlap with the PCI-AHB window 1 area. Figure 31.4 shows an image of mapping in such cases.

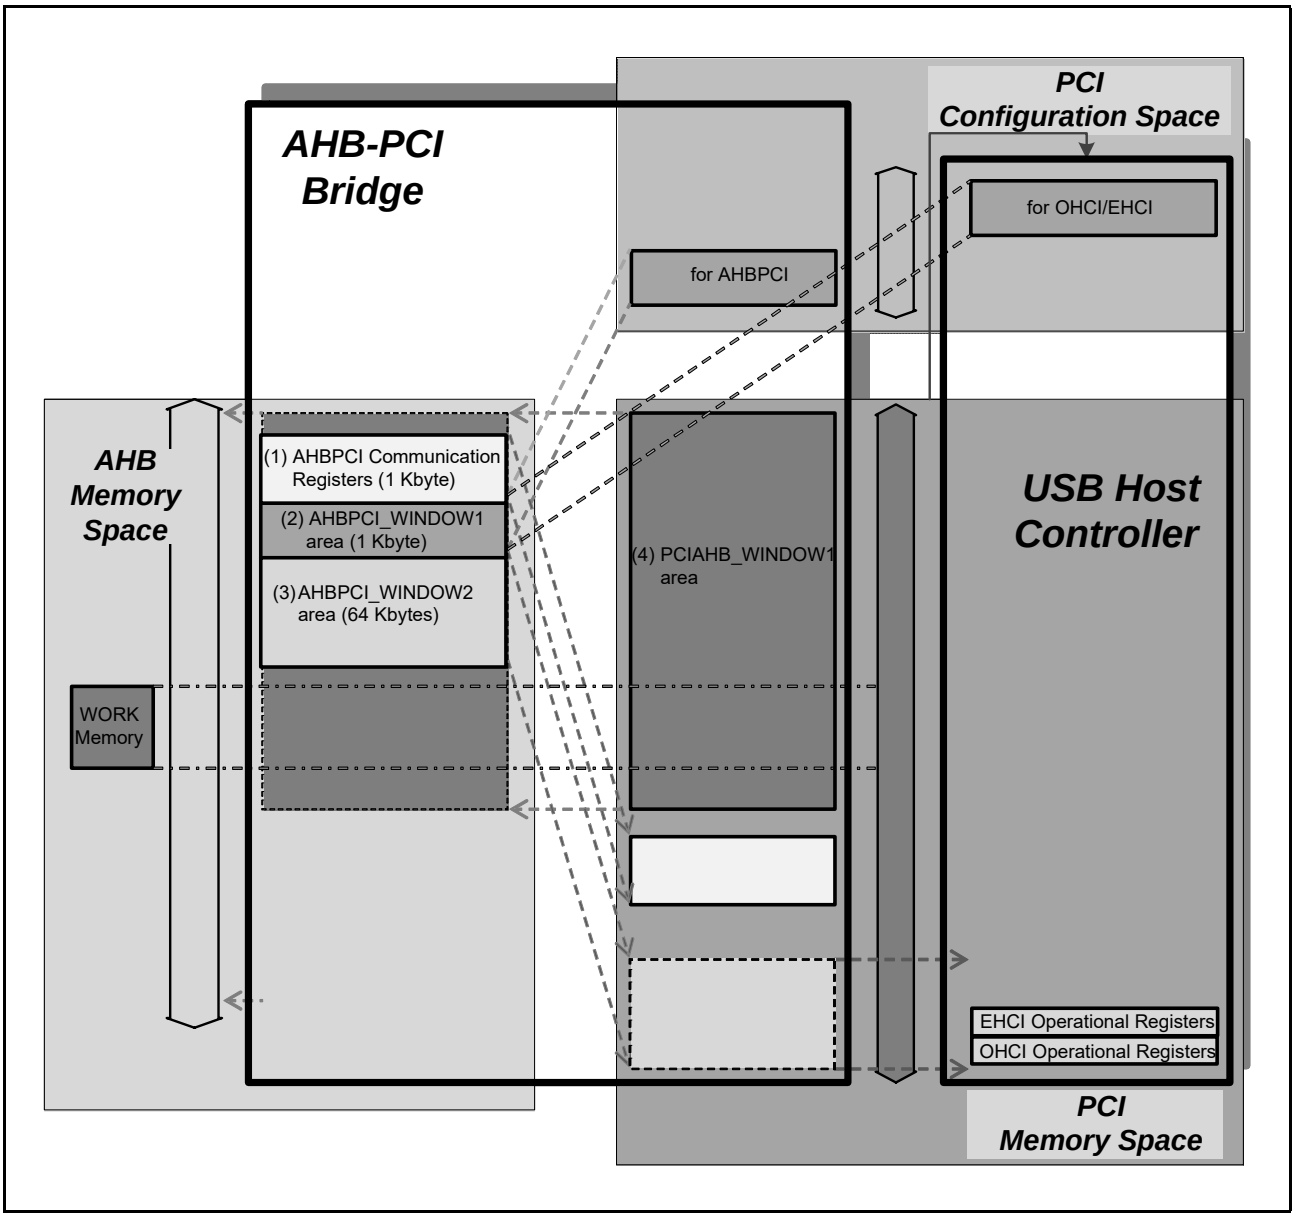

Figure 31.4 Image of AHB and PCI Space Mapping (when Areas Overlap)

Figure 31.5 and Table 31.6 show the registers used for AHB and PCI space mapping and the relationship between the settings in the registers and the mapping in the spaces.

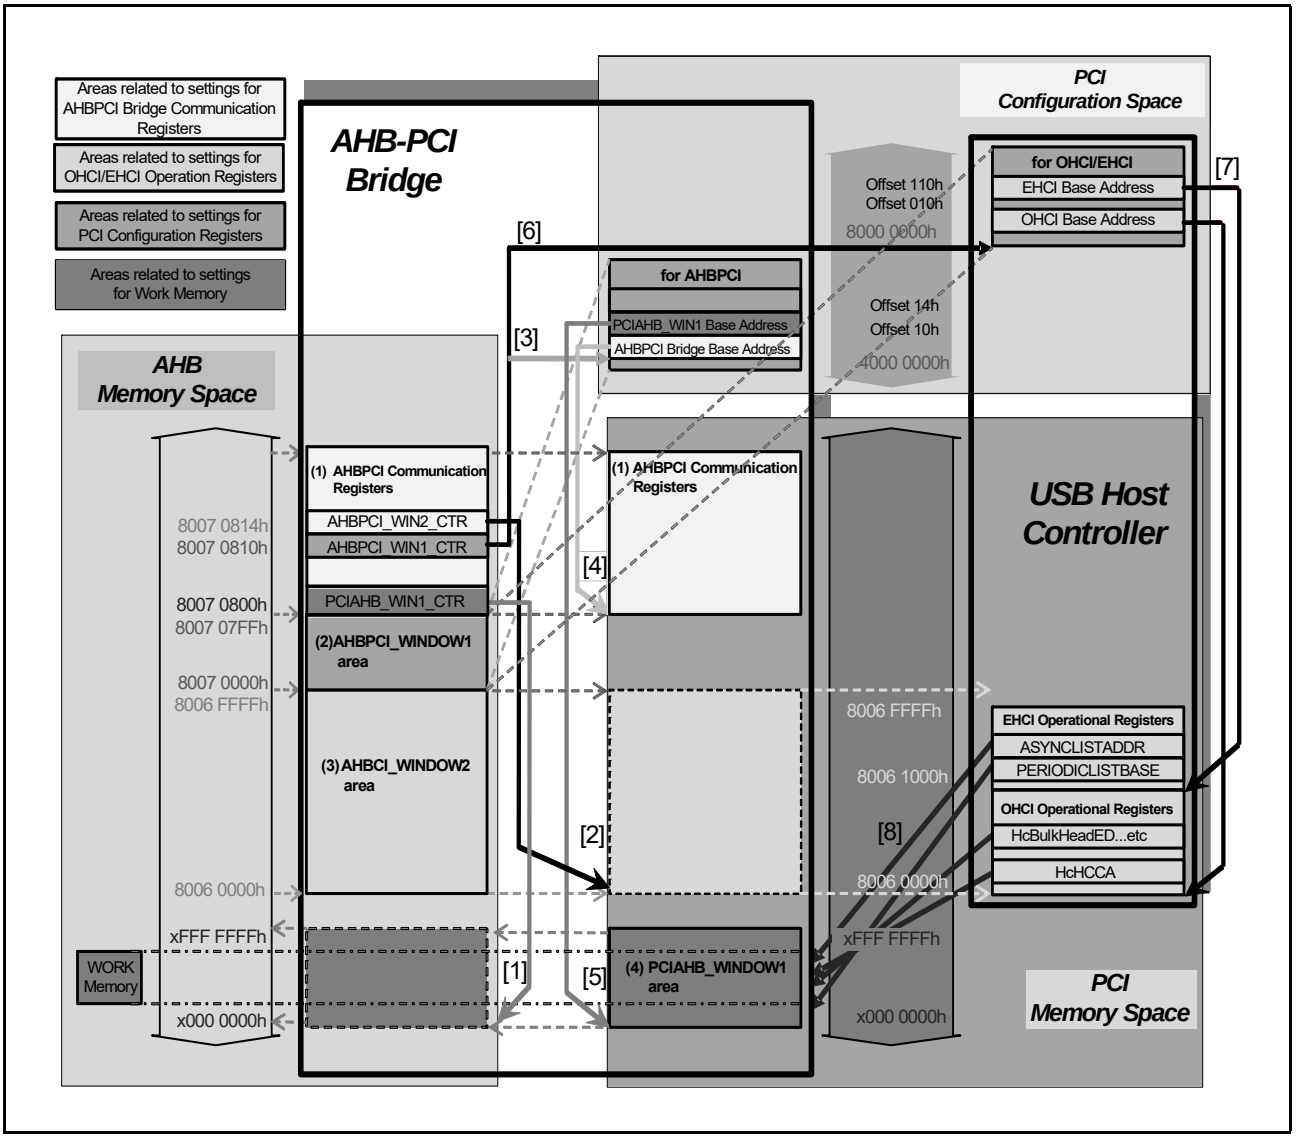

Figure 31.5 Relationship between the Address Setting in the Registers and AHB and PCI Space Mapping

Table 31.6 Descriptions of Address Settings in Registers

Register	Description
[1] PCIAHB_WIN1_CTR	When the host logic performs master access to the PCI-AHB window 1 area, the AHB bus address is converted to the base address specified in this register. In general usage, specify an area including the work memory to be used.
[2] AHBPCI_WIN2_CTR	When the AHB-PCI window 2 area is accessed, the PCI bus address is converted to the base address specified in this register. In general usage, this register can be set to the same value as that for the AHB-PCI window 2 area. However, if this area overlaps the area specified in [1] (the area including work memory), specify an appropriate address to avoid overlap.
[3] AHBPCI_WIN1_CTR	When the base address is set to 4000_0000h in this register, the PCI configuration registers for AHB-PCI are accessed.
[4] AHBPCI Bridge Base Address	This register specifies the base address of the AHB-PCI bridge in the PCI space. This register is not accessed from the PCI bus, but specify an appropriate address to avoid overlap with other areas.
[5] PCIAHB_WIN1 Base Address	This register specifies the base address of the PCI-AHB window 1 area in the PCI space. In general usage, specify the same base address as [1].
[6] AHBPCI_WIN1_CTR	When the base address is set to 8000_0000h in this register, the PCI configuration registers for OHCI/EHCI are accessed.
[7] OHCI/EHCI Base Address	This register specifies the base address of the OHCI/EHCI operational registers in the PCI space. In general usage, the OHCI base address is specified as the same value as specified in [2]. The EHCI base address is set to a value obtained by adding an offset of 1000h to the base address specified in [2].
[8] Various OHCI/EHCI Operational Registers	After settings of [1] to [7] are completed, the host logic can access data (such as descriptors) expanded in the work RAM on the AHB bus through the PCI. The following registers specify the addresses of data stored in work RAM. • OHCI/EHCI operational registers – HcHCCA register – HcPeriodicCurrentED register – HcControlHeadED register – HcControlCurrentED register – HcBulkHeadED register – HcBulkCurrentED register – HcDoneHead register • EHCI operational registers – PERIODICLISTBASE register – ASYNCLISTADDR register

31.4.1.1 Access to PCI Configuration Registers

The registers in the PCI configuration spaces are accessed through the AHB-PCI window 1 area (addresses 10000h to 107FFh: 2-Kbyte space). Before access, make appropriate settings in the AHBPCI_WIN1_CTR register. The following shows the settings of the AHBPCI_WIN1_CTR register to access the PCI configuration spaces for OHCI/EHCI and AHB-PCI bridge.

Table 31.7 AHBPCI_WIN1_CTR Register Setting

	AHBPCI_WIN1_CTR Register Setting	
Area to be Accessed	**PCIWIN1_BASEADR[31:11]**	**PCICMD[2:0]**
OHCI/EHCI PCI Configuration Space	Only bit 31 is set to 1.	101b
AHB-PCI Bridge PCI Configuration Space	Only bit 30 is set to 1.	

31.4.1.2 Access to OHCI/EHCI Operational Registers

When OHCI/EHCI operational registers are accessed, it is necessary to make settings in the OHCI/EHCI PCI configuration register and the AHBPCI_WIN2_CTR register as well as PCI space address mapping. The following shows the necessary settings.

Table 31.8 Necessary Settings for Access to OHCI/EHCI Operational Registers

Locations of Settings	**Settings**
OHCI/EHCI PCI configuration apace Offset 04h (Command, Status) Bit1 (Memory space)	1 (Access to memory space is enabled)
AHBPCI_WIN2_CTR register bit[3:1] PCICMD[2:0]	011b (Memory read or memory write)

31.5 Clock Lines

31.5.1 Externally Supplied Clocks

The following three clock signals are supplied from within the chip to the USB host controller of the RZ/T1.

Table 31.9 List of Externally Supplied Clocks

Clock Signal	Function	Frequency
PCLKA	AHB clock AHB clock for power management	150 MHz
USBMCLK	Reference clock	50 MHz
USBPCLK	PCI clock inside the USB host controller	30 MHz

31.5.2 Clock Distribution Diagram

Figure 31.6 shows the clock distribution diagram of this system.

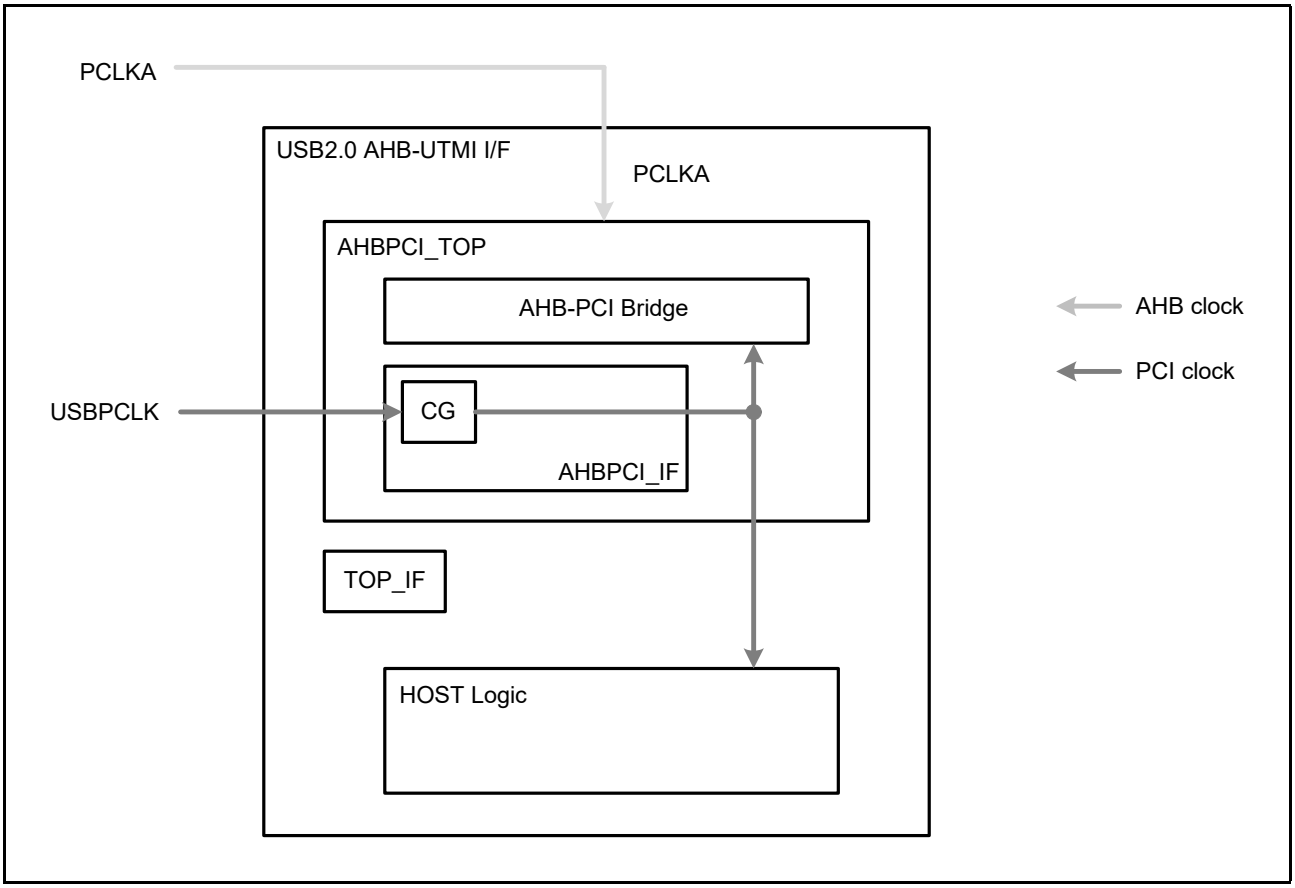

Figure 31.6 Clock Distribution Diagram

31.6 Interrupts

31.6.1 Interrupt Control Registers

31.6.1.1 U2H_INT Control Registers

U2H_INT is an interrupt signal generated by the AHB-PCI bridge. Registers in the AHB-PCI bridge are used to check and clear the interrupt state and to enable interrupts.

Table 31.10 U2H_INT Control Registers

Operation	Control Register
Check and clear interrupt state	PCI_INT_STATUS register
Enable interrupts	PCI_INT_ENABLE register

31.6.1.2 U2H_OHCI_INT Control Registers

U2H_OHCI_INT is the INTA interrupt signal from the host logic. Each interrupt is controlled basically through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB-PCI bridge should be set.

Table 31.11 U2H_OHCI_INT Control Registers

Operation	Control Register
Check and clear interrupt state	HcInterruptStatus register
Enable interrupts	HcInterruptEnable register HcInterruptDisable register PCI_INT_ENABLE register (bit 16 (USBH_INTAEN))

31.6.1.3 U2H_EHCI_INT Control Registers

U2H_EHCI_INT is the INTB interrupt signal from the host logic. Each interrupt is controlled basically through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB-PCI bridge should be set.

Table 31.12 U2H_EHCI_INT Control Registers

Operation	Control Register
Check and clear interrupt state	USBSTS register
Enable interrupts	USBINTR register PCI_INT_ENABLE register (bit 17 (USBH_INTBEN))

31.6.1.4 U2H_PME_INT Control Registers

U2H_PME_INT is the PME interrupt signal from the host logic. Each interrupt is controlled basically through registers in the host logic, but to assert the interrupt signal, the interrupt enable bit in the AHB-PCI bridge should be set.

Table 31.13 U2H_PME_INT Control Registers

Operation	Control Register
Check and clear interrupt state	PCI Configuration register for OHCI/EHCI offset 44h
Enable interrupts	PCI Configuration register for OHCI/EHCI offset 44h PCI_INT_ENABLE register (bit 19 (USBH_PMEEN))

31.6.2 U2H_BIND_INT

The U2H_BIND_INT interrupt signal is generated as the logical OR of four interrupt source signals (U2H_INT, U2H_OHCI_INT, U2H_EHCI_INT, and U2H_PME_INT).
The states of the U2H_PME_INT, U2H_OHCI_INT, and U2H_EHCI_INT signals are reflected in the PCI_INT_STATUS register in the AHB-PCI bridge. Read the register to check which source was responsible for a generated interrupt.

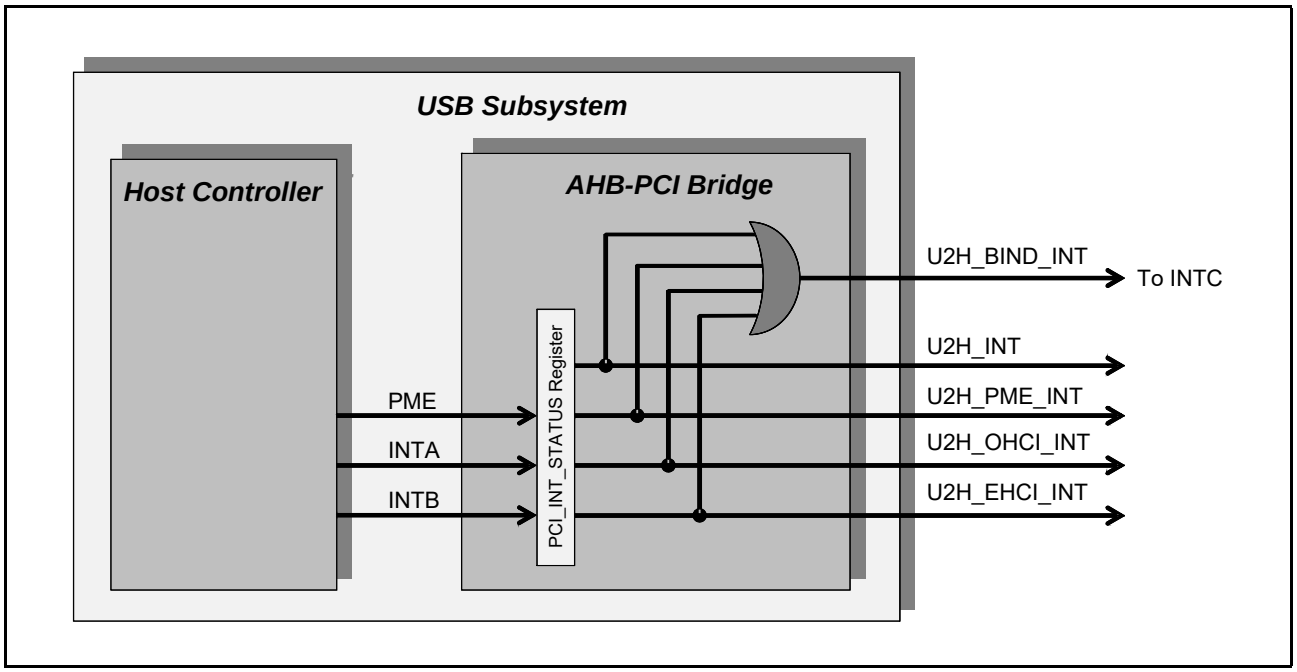

Figure 31.7 Image of Interrupt Signal Integration

31.6.3 Time Required to Clear Interrupt Signals

An interrupt generated in the USB host controller may be falsely detected multiple times because, depending on the access state on the internal bus, it may take a long time to actually clear the interrupt after the register for clearing the interrupt source is written to (see Figure 31.8 Time Required to Clear an Interrupt) due to the posted write operation of the AHB bridge.
A measure should be taken to prevent false detection before the next interrupt is detected after the register access for clearing the interrupt is completed.
For example, after accessing the register for clearing the interrupt source (1), access any register in the host logic (2). Register access (2) waits (SHREADY/MHREADY = 0 or RETRY response) until (1) is completed, and the interrupt is cleared without fail when register access (2) is completed.

(1) Host Logic
It may take time to clear a U2H_OHCI_INT, U2H_EHCI_INT, or U2H_PME_INT interrupt after the register for clearing the interrupt is accessed.
This usually takes approximately 300 ns when PCLKA is 150 MHz, but in the worst case when master transfer is in progress on the internal PCI bus, this takes 36 USBPCLK cycles + 3 PCLKA cycles + two 12-MHz clock cycles; this is approximately 1.4 µs when USBPCLK is 30 MHz.

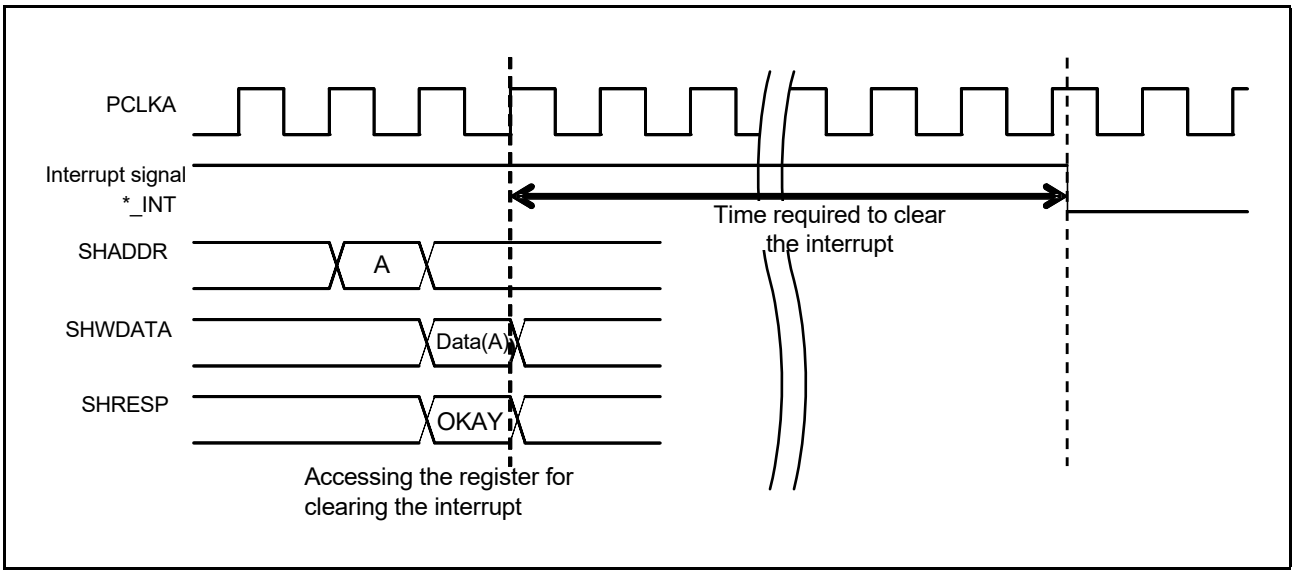

Figure 31.8 Time Required to Clear an Interrupt

31.7 Overcurrent Control and VBUS Control

31.7.1 Overcurrent Control

This section describes the operation of the USB_OVRCUR and USB_VBUSEN signals used for overcurrent detection at the USB port and VBUS control.

31.7.1.1 USB_OVRCUR and USB_VBUSEN Signal Functions

Table 31.14 shows the meaning of the USB_OVRCUR and USB_VBUSEN signals.

Table 31.14 USB_OVRCUR and USB_VBUSEN

Pin	I/O	Level	Meaning
USB_OVRCUR	Input	1	No overcurrent has been detected.
		0	Overcurrent has been detected.
USB_VBUSEN	Output	1	Power supply to VBUS is on.
		0	Power supply to VBUS is off.

31.7.1.2 Conditions for Asserting and Deasserting USB_VBUSEN Output Signal

Figure 31.9 is a timing chart for USB_OVRCUR and USB_VBUSEN assertion and deassertion.

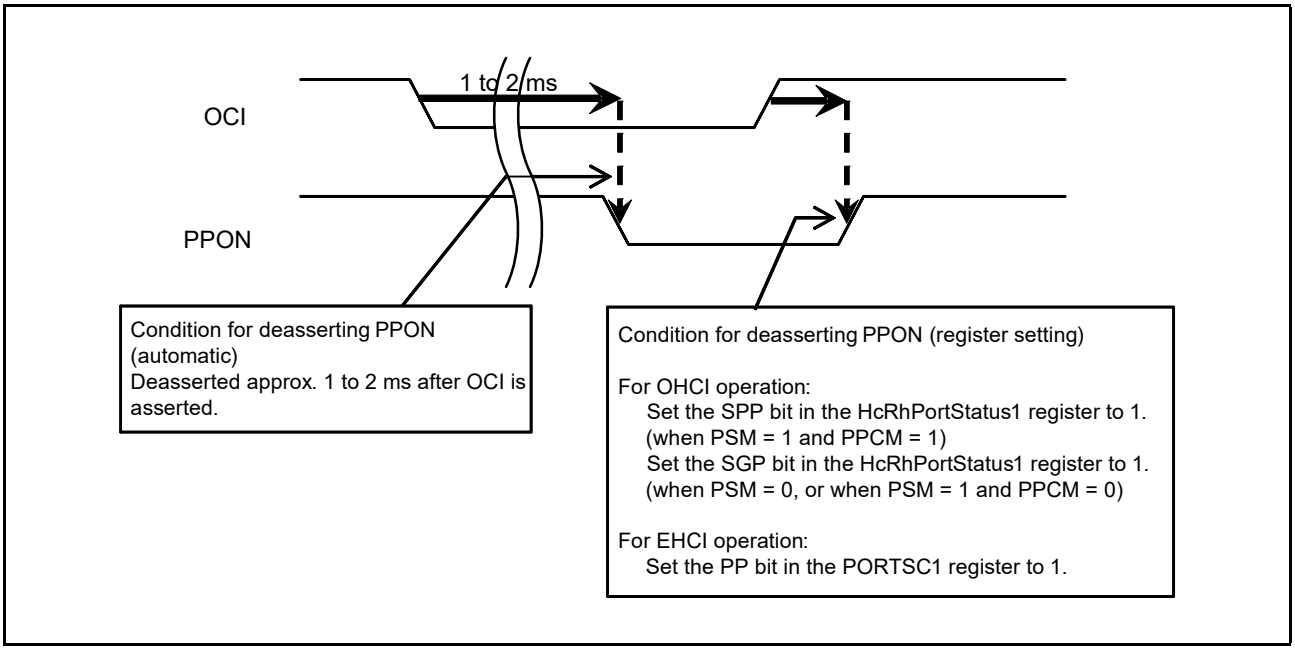

Figure 31.9 Timing Chart for USB_OVRCUR and USB_VBUSEN Assertion and Deassertion

After USB_OVRCUR is deasserted, USB_VBUSEN is not asserted automatically. USB_VBUSEN is asserted when software sets the port power bit after USB_OVRCUR is deasserted.

31.7.2 VBUS Control

When the USB port is not used, VBUS can be stopped to reduce power consumption by connecting the USB_OVRCUR and USB_VBUSEN pins to the high-side switch (although this may not be possible depending on the connections with peripheral circuits).
The relationship between USB_VBUSEN and VBUS is shown below.

Table 31.15 Relationship between USB_VBUSEN and VBUS

USB_VBUSEN	VBUS
0	Stopped
1	Operated

The USB_VBUSEN operation when USB_OVRCUR is asserted depends on the settings in the PCI configuration register and OHCI operational registers as shown below.

Table 31.16 Register Settings and USB_VBUSEN Operation

OHCI Operational Registers				
HcRhDescriptorA Register			HcRhDescriptorB Register	USB_VBUSEN Output Pin Operation
NOCP Bit	NPS Bit	PSM Bit	PPCM[1] Bit	
1	—	—	—	Fixed to 1
—	1	—	—	Fixed to 1
0	0	0	—	Deasserted (0) when USB_OVRCUR is asserted (0)
		1	0	
			1	

Note: When NPS = 1, the host logic detects an overcurrent but does not deassert USB_VBUSEN.

31.7.3 Initial Settings of PPON1

ON and OFF of PPON1 (PortPower) is controlled by the port control register of OHCI/EHCI operational registers listed below in general usage after reset without setting the NOCP and NPS bits in the HcRhDescriptorA register. PPON1 is turned ON when at least one of the following bits (SPP, SGP, and PP) is ON.
In general, the following bits (SPP, SGP, and PP) are cleared to 0 when an overcurrent is detected.

Register		Bit	Symbol
OHCI operation	HcRhPortStatus1 register	8	SPP
	HcRhPortStatus register	16	SGP*1
EHCI operation	PORTSC1 register	12	PP

Note 1. This is not generally used with the single-port version.
For PPON control by this bit, the bit must be in the state of PSM = 0, or PSM = 1 and PPCM = 0.

PPON1 is turned on by setting the NOCP or NPS bit to 1 regardless of the Port Power bit of the above ports.
The initial settings of the PPON1 control bits (SPP, SGP, PP, NOCP, and NPS) mentioned above are all 0 (OFF). Setting these bits to 1 (ON) during initial setting, the procedure in the following flow is required.

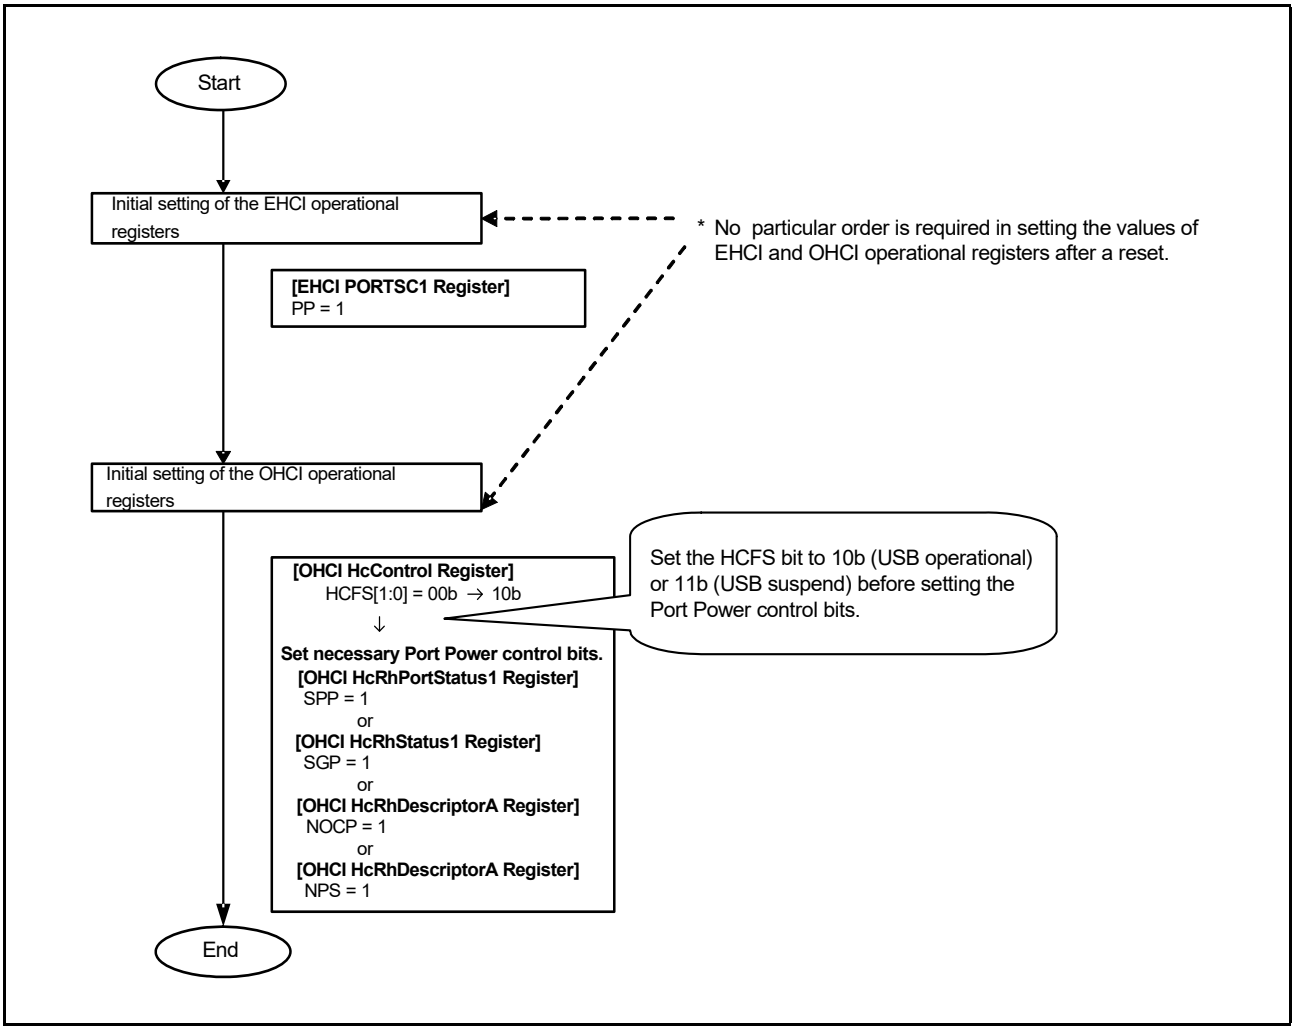

Figure 31.10 Flow of PPON1 Initial Settings

31.7.4 Procedure for USB_VBUSEN Control Regarding Overcurrent Detection

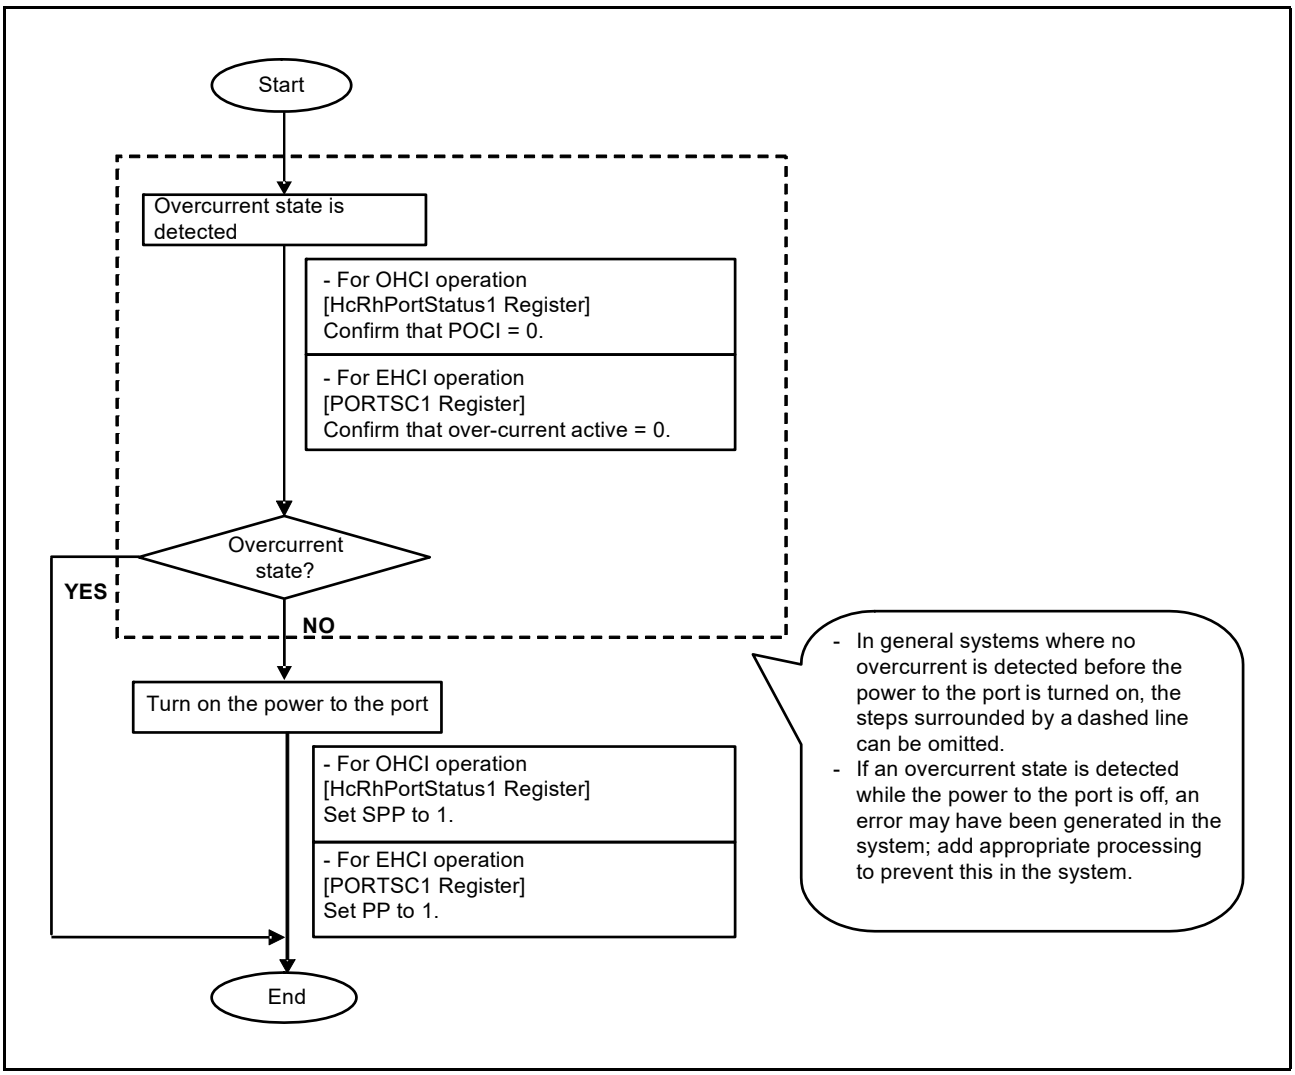

Figure 31.11 Flow for USB_VBUSEN Control Regarding Overcurrent Detection

31.7.5 Procedure for USB_VBUSEN Setting

The following shows the procedure for USB_VBUSEN setting in a system where USB_OVRCUR may be active (0) at system start-up.

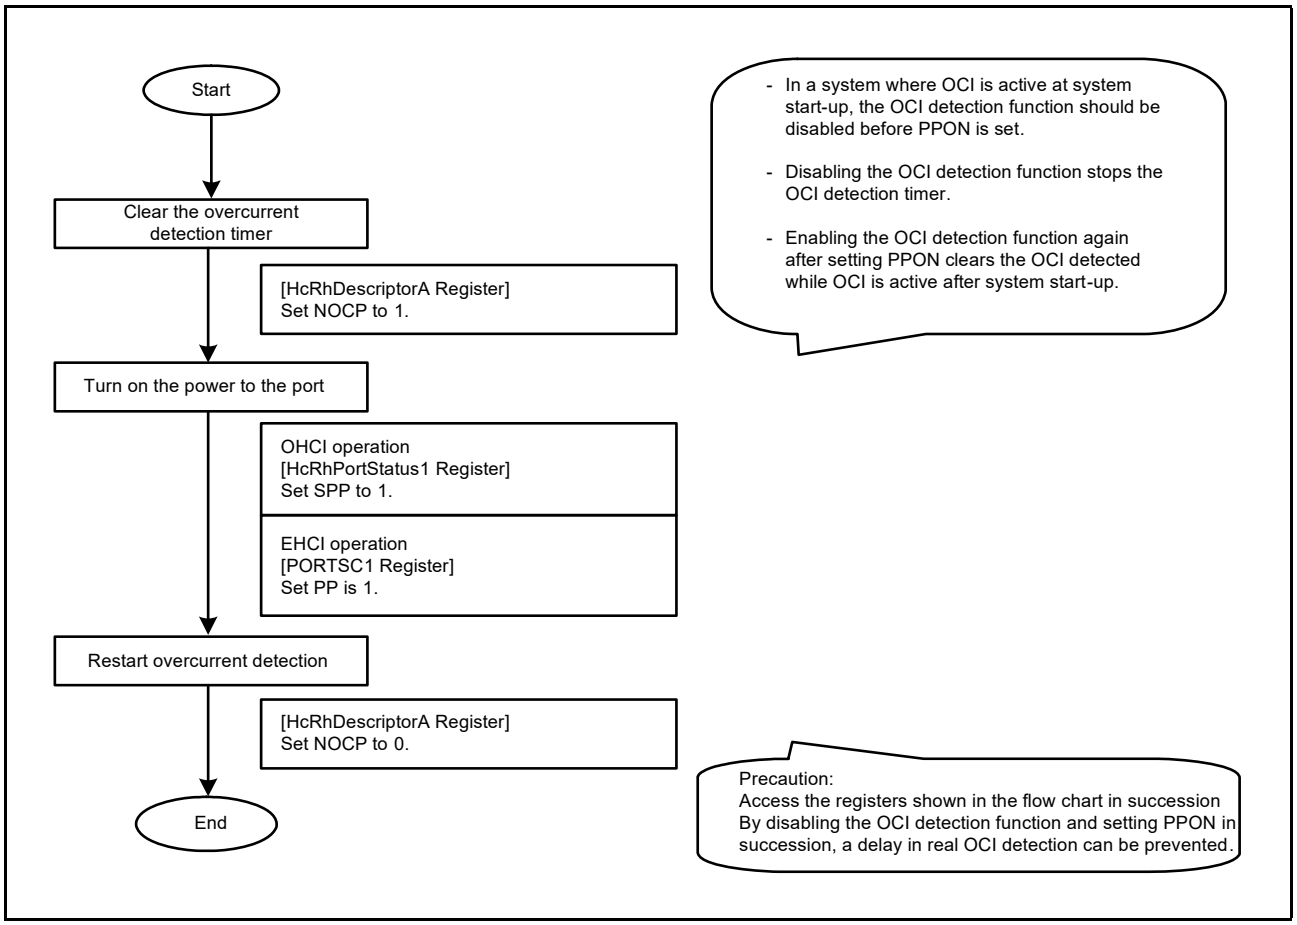

Figure 31.12 Flow for USB_VBUSEN Setting

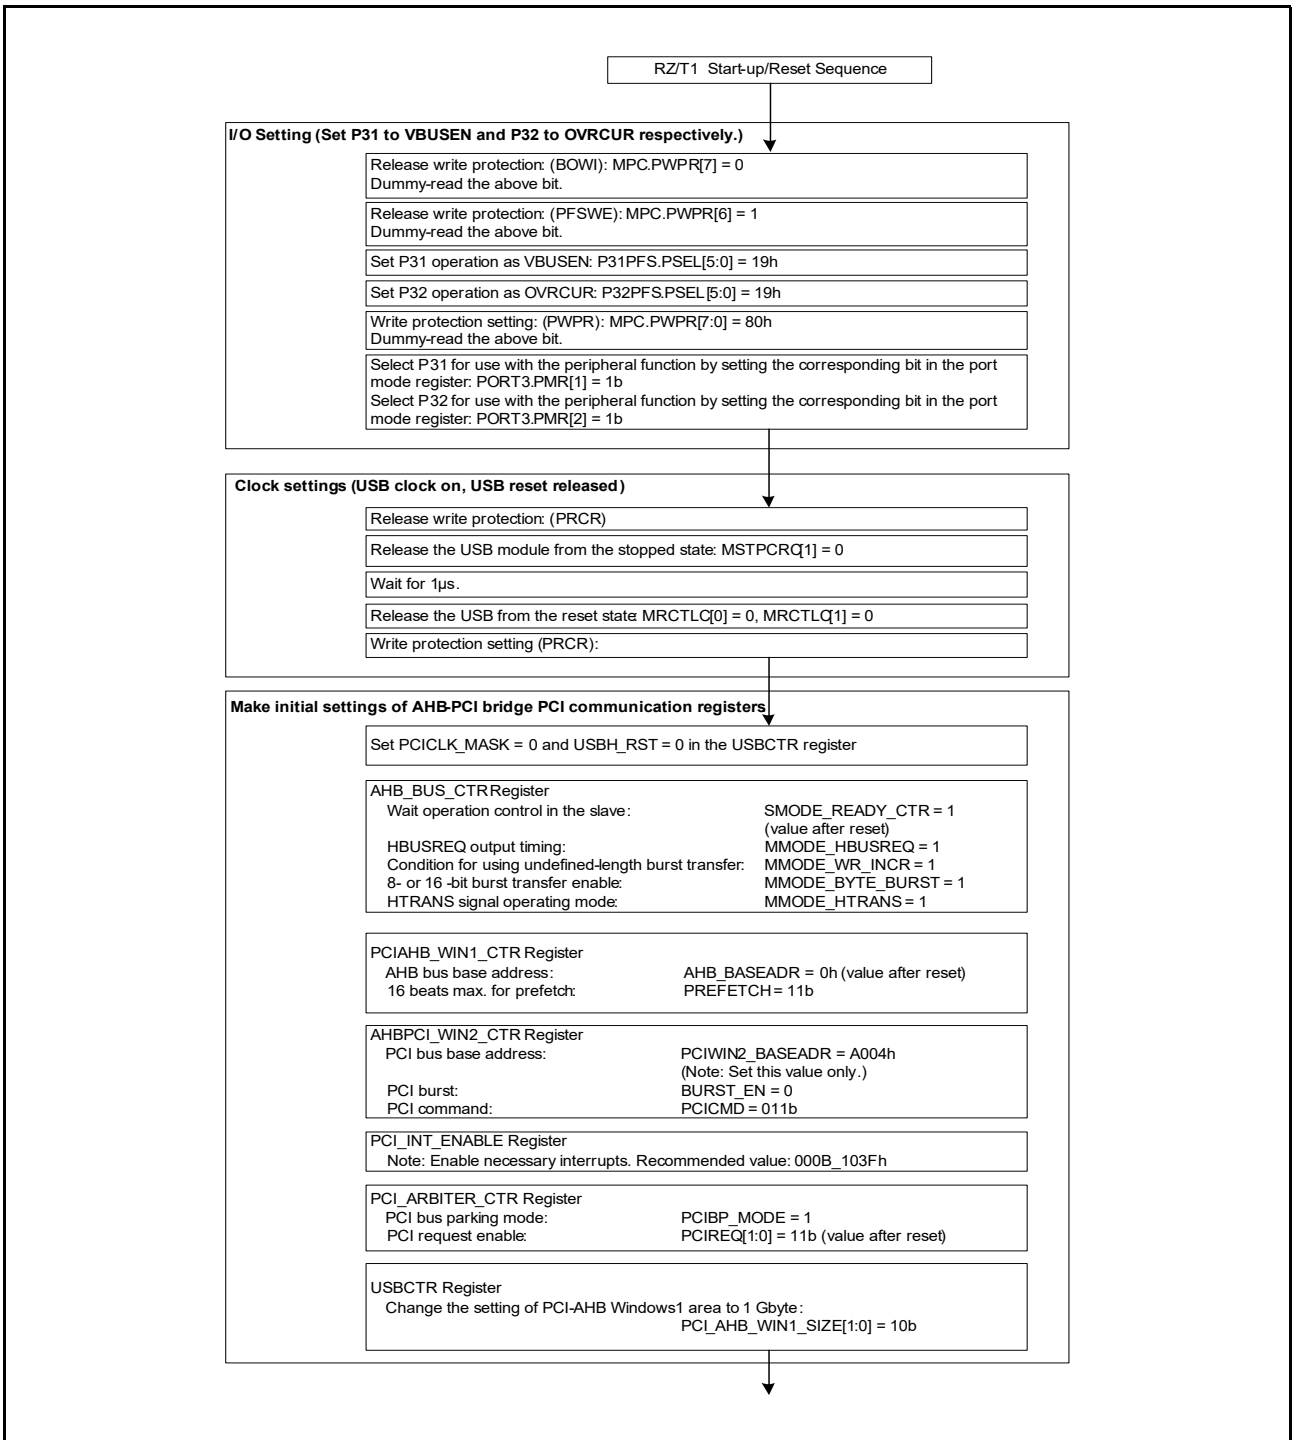
31.8 Operating Procedures

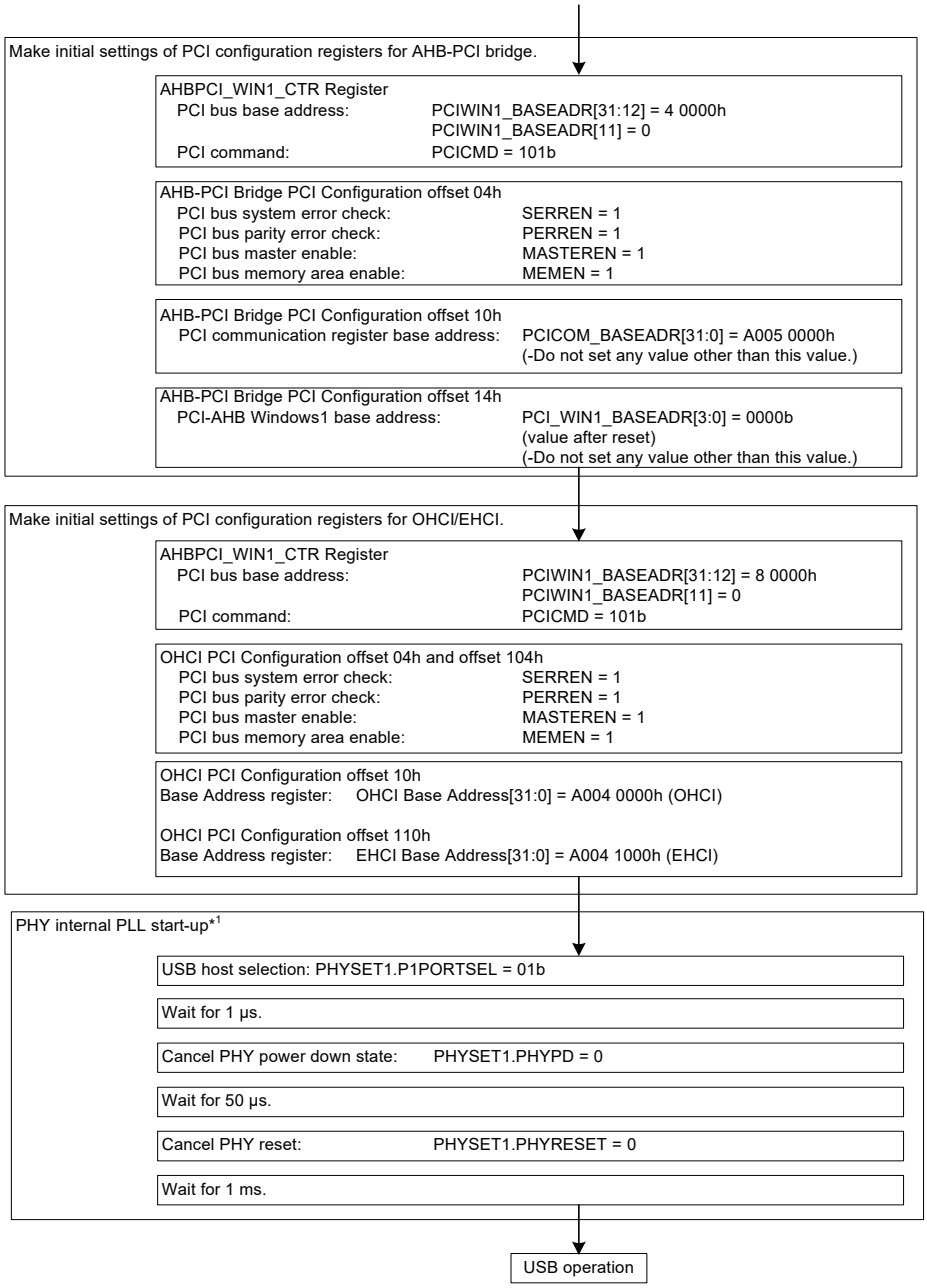
31.8.1 Initial Setting Sequence

31.8.1.1 Sample of Initial Settings

This section shows sample initial settings to implement the following functions.

- Access to OHCI/EHCI operational registers through AHB-PCI window 2 registers.
- Data transfer from the host logic to the AHB bus.





Note 1. A halt of the operation of the PHY internal PLL by setting PHY Power-Down (the PHYSET1.PHYPD bit is 1) and PHY reset (PHYSET1.PHYRESET bit is 1) is prohibited once the PHY internal PLL is activated.

Figure 31.13 Initial Setting Sequence

31.8.2 USB Host Transfer Procedure

For the USB host transfer procedure, see the following OHCI and EHCI specifications.

- Open Host Controller Interface Specification for USB Rev 1.0a
- Enhanced Host Controller Interface Specification for Universal Serial Bus Revision 1.0

This section gives only supplementary information regarding DMA stop.

31.8.2.1 Stopping DMA Transfer

The AHB-PCI Bridge core does not have a function for starting or stopping DMA transfer. The PCI bus cycle started by the host logic working as the master is output to the AHB bus as a DMA transfer without change.
DMA transfer is done in the following two cases.

(1) The current frame number is written to memory.
(2) The descriptors and data expanded in memory are read or written to for list processing.

Note: The frame number is automatically written at frame cycle intervals when the USB state is operational.

To stop DMA transfer, shift the USB state to Suspend or Reset.
To suspend only the list processing in (2), clear the bit for enabling list processing (BLE, CLE, IE, or PLE bit in the HcControl register); the list processing stops at the next frame.

32. USB 2.0 HS Function Module (USBf)

32.1 Overview

The USB module of this LSI is a dual-role device that has USB 2.0 host and function modules. However, it does not have a facility for detecting the ID and so does not support On-the-Go (OTG) functionality.
This LSI handles a single USB port for either host controller or function controller operation. The port connection path select input signal bits (PHYSET1.P1PORTSEL[1:0]) are used to switch between host controller and function controller operation.
Since operation as a host controller or a function controller are exclusive of each other, dynamic switching between the types of operation is not possible.

This section describes function controller operation.

The USBf module supports high-speed transfer and full-speed transfer defined by the USB 2.0 specification.

This LSI supports all transfer types that are defined in the USB specification. It incorporates an 8-Kbyte buffer memory for data transfer and can use up to 10 pipes. Pipes 1 to 9 can be assigned an arbitrary endpoint number according to the user system. The controller is equipped with a dedicated DMA interface as a local bus interface which is independent of the CPU bus interface, making it suitable for systems requiring high-speed, large-capacity data transfer.

Table 32.1 Specifications of the USB Module (1 / 2)

Item	Description
For High-Speed USB	• Built-in USB function controller
For all types of USB transfer	• Support for all types of USB transfer, including isochronous • Control transfer • Bulk transfer • Interrupt transfer (high-bandwidth transfers not supported) • Isochronous transfer (high-bandwidth transfers not supported)
Bus interface	• Two DMA interfaces available - The interface with the DMAC is selectable and DMA transfer is independent of the CPU bus interface • High-speed data transfer for access to the internal FIFOs at 60 Mbytes/second (when the bus width is 32 bits)
Pipe configuration	• 8 Kbytes of buffer memory for USB communications • Up to 10 pipes can be selected (including the default control pipe) • Programmable pipe configuration • Any endpoint number can be assigned to pipes 1 to 9 • Transfer conditions that can be set for each pipe are listed below. Pipe 0: Control transfer, single buffer fixed at 64 bytes Pipes 1 and 2: Bulk transfer or isochronous transfer can be selected, continuous transfer mode, programmable buffer size (specifiable as up to 2 Kbytes, double buffer is also specifiable) Pipes 3 to 5: Bulk transfer, continuous transfer mode, programmable buffer size (specifiable as up to 2 Kbytes, double buffer is also specifiable) Pipes 6 to 9: Interrupt transfer, single buffer fixed at 64 bytes
Features of function controller operation	• High-speed (480 Mbps) and full-speed transfer (12 Mbps) are supported • Automatic recognition of high-speed operation or full-speed operation based on automatic response to the reset handshake • Control transfer stage monitoring • Monitoring of device state • Automatic response to SET_ADDRESS requests • NAK response interrupt function (NRDY) • SOF interpolation

Table 32.1 Specifications of the USB Module (2 / 2)

Item	Description
Other functions	• Judging the end of transfer on the basis of a transaction count • Adjustable timing for BRDY interrupt event notification (BFRE) • Automatic clearing of the buffer memory after the data for the pipe specified in the DxFIFO port has been read (DCLRM) • NAK setting for response PID generated by end of transfer (SHTNAK) • Only self-powered mode is supported (bus-powered mode is not supported).

Figure 32.1 is a block diagram of the USB module.

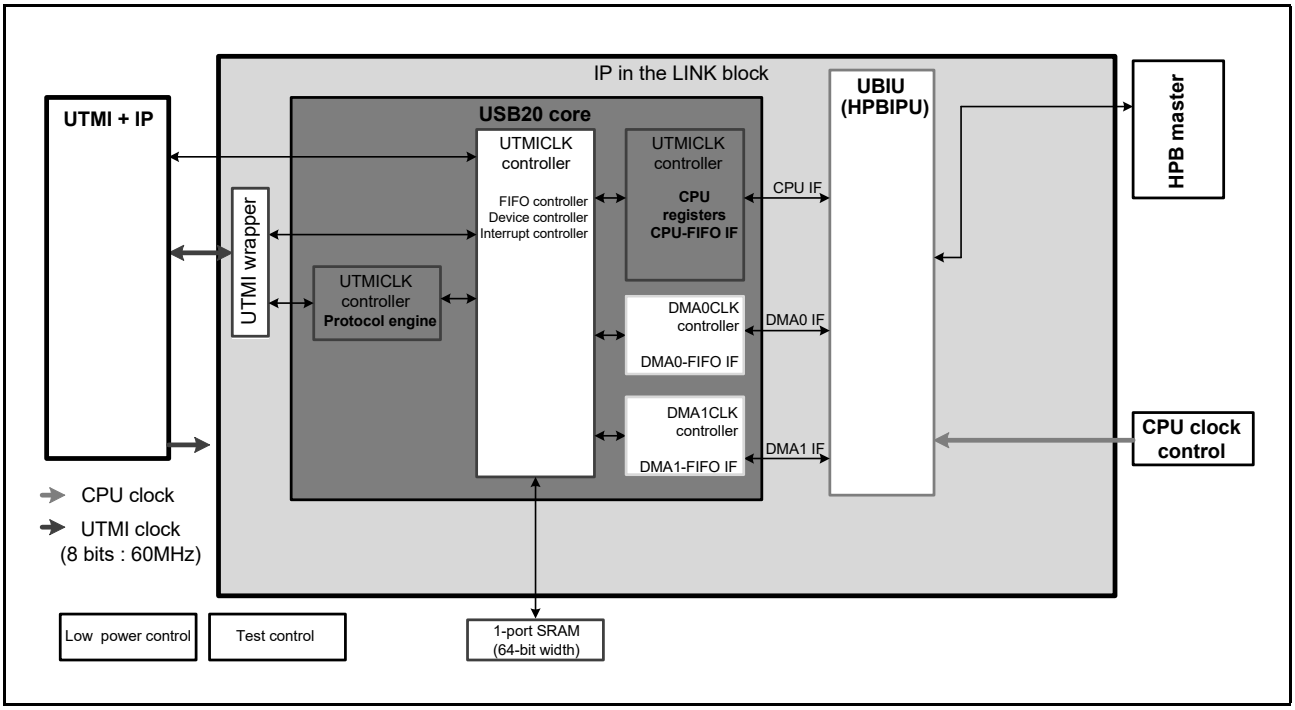


Figure 32.1 Block Diagram of the USB Module

Data transfer between this controller and the host controller connected to the USB bus uses buffer memory assigned to each pipe. For communication between this controller and the host controller, this controller converts the data stored in buffer memory into USB data packets and outputs them to the USB bus serially, and also inputs data packets from the USB bus and stores them in buffer memory.

32.1.1 Functional Overview

32.1.1.1 Identification of the USB Transfer Speed

The hardware can automatically identify the USB transfer speed.

32.1.1.2 Bus interface

(1) How to access the FIFO buffer memory

The following two types of access are available for the FIFO buffer memory for USB data transfers. To read from or write to the FIFO buffer memory, access (read or write) the FIFO ports from the CPU (DMAC).

1. CPU access
   Specify a FIFO port address and write data to the FIFO buffer memory or read data from the FIFO buffer memory.
2. DMA access
   Specify a FIFO port address through the DMAC in the CPU or the dedicated DMAC and write data to the FIFO buffer memory or read data from the FIFO buffer memory.

USB data transfer is done in little endian. The byte endian swap function is available for FIFO port access; for 16-bit or 32-bit access, the endian can be switched through register settings.

32.1.1.3 USB Event

This controller sends an interrupt to the user system to notify an event in USB operation. This controller asserts the UCL_Dx_DREQ (interrupt source [43] or [44]) signal to notify that the pipe selected for the DMA interface has become ready for access.

Sending interrupts for notification can be enabled or disabled separately for each interrupt type and source through software settings.

32.1.1.4 USB Data Transfer

This controller performs all types of USB data transfer: control transfer, bulk transfer, interrupt transfer, and isochronous transfer. The following numbers of pipes are available for each transfer type.
One pipe dedicated to control transfer
Four pipes dedicated to interrupt transfer
Three pipes dedicated to bulk transfer
Two pipes selectively used for bulk transfer or isochronous transfer

Each pipe should be set up as necessary for the desired USB transfer in accordance with the user system; for example, transfer type, endpoint number, or maximum packet size.

This controller has an 8-byte buffer memory. For pipes dedicated for bulk transfer or selective pipes for bulk transfer or isochronous transfer, buffer memory assignment, buffer operating mode setting, or other necessary settings should be made in accordance with the user system. By setting the buffer operating mode, such as double buffer structure or continuous data packet transfer mode, fast data transfer is achieved with fewer interrupts.

CPU and DMA controller access to the buffer memory is made through three FIFO port registers.

32.1.1.5 Functions for Access from Direct Memory Access Controller (DMAC)

This controller provides two channels of the DMA interface having the following functions.
(1) Notification of the end of transfer using a transfer end signal
(2) Automatic clearing of the FIFO buffer when a zero-length packet is received
(3) Judging the end of transfer using the transaction counter

32.2 Register Descriptions

32.2.1 System Configuration Control

32.2.1.1 System Configuration Control Register 0 (SYSCFG0)

Address(es): A006 0000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	HSE	—	DRPD	DPRPU	—	—	—	USBE
Value after hardware reset:	x	x	x	x	x	x	x	0	0	0	1	0	x	x	x	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b0	USBE	USB Block Operation Enable	Enables or disables operation of the USB block. 0: USB block operation is disabled. 1: USB block operation is enabled.	R/W	R
b3 to b1	—	Reserved	When writing to these bits, write 0.	R/W	—
b4	DPRPU	D+ Line Resistor Control	Enables or disables pulling up the D+ line in function controller operation. 0: Pulling up the line is disabled. 1: Pulling up the line is enabled.	R/W	R
b5	DRPD	D+/D- Line Resistor Control	Always set 0 at initialization.	R/W	R
b6	—	Reserved	When writing to this bit, write 0.	R/W	—
b7	HSE	High-Speed Operation Enable	Enables or disables high-speed operation. 0: High-speed operation is disabled (full-speed). 1: High-speed operation is enabled (the controller detects the communication speed)	R/W	R
b15 to b8	—	Reserved	When writing to these bits, write 0.	R/W	—

Note: Writing to this register is possible even while the UTMI clock (output of the clock signal from the PLL in the USB) is stopped. Note however that any values that are set while the UTMI clock is stopped are reflected after oscillation of the UTMI clock is restarted.

USB Block Operation Enable Bit (USBE)

The setting of the USBE bit enables or disables operation of the USB block.
When the USBE bit is modified from 1 to 0, this controller initializes the bits listed in Table 32.2.

Table 32.2 Registers Initialized by Writing USBE = 0

Register Name	Bit Name
SYSSTS0	LNST
DVSTCTR0	RHST
INTSTS0	DVSQ
USBADDR	USBADDR
USBREQ	bRequest bmRequestType
USBVAL	wValue
USBINDX	wIndex
USBLENG	wLength

The value of this bit must be changed when SUSPM = 1 and after the UTMI clock oscillation is started.

D+/D- Line Resistor Control (DRPD and DPRPU)

Settings related to USB data bus resistance are given in Table 32.3, USB Data Bus Resistance Control. Use the DRPD and DPRPU bits to select USB data bus resistance.

Table 32.3 USB Data Bus Resistance Control

Settings		USB Data Bus Resistance Control		
DRPD	DPRPU	D- Line	D+ Line	Remarks
0	0	Open	Open	
0	1	Open	Pull-up	Make these settings when the module is used as a function controller.
1	0	Pull-down	Pull-down	Setting prohibited
1	1	Pull-down	Pull-up	Setting prohibited

- D+ pull-up resistance control for function controller operation (DPRPU)

When this bit set to 1, this controller pulls up the D+ line to 3.3V and can notify the USB host that the function module is attached.
The controller cancels pulling-up of the D+ line by modifying this bit from 1 to 0, and the state for the USB host can be shown as detached.

Settings in these bits should be made set at the same time as that of PHYSET1.PHYVBUSIN.

Hi-Speed Operation Enable Bit (HSE)

Setting this bit to 1 enables high-speed operation. Setting the HSE bit to 1 lets this controller perform high-speed or full-speed operation based on the results of reset handshake.

Setting the HSE bit to 0 lets this controller perform full-speed operation.
On the other hand, setting the HSE bit to 1 lets this controller perform the reset handshake protocol and then perform high-speed or full-speed operation automatically according to the results.

This bit can be modified when DPRPU = 0.

32.2.1.2 System Configuration Control Register 1 (SYSCFG1)

Address(es): A006 0002h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	BWAIT[5:0]					
Value after hardware reset:	x	x	0	0	0	0	0	0	x	x	0	0	1	1	1	1
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b5 to b0	BWAIT[5:0]	CPU Bus Access Wait Specification	Specify the number of wait cycles for access to this controller. b5 b0 000000: 0 wait cycles (2 access cycles) : : 000010: 2 wait cycles (4 access cycles) : : 000100: 4 wait cycles (6 access cycles) : : 001111: 15 wait cycles (17 access cycles) (value after a reset) : : 111111: 63 wait cycles (65 access cycles)	R/W	R
b15 to b6	—	Reserved	When writing to these bits, write 0.	R/W	—

CPU Bus Access Wait Specification Bit (BWAIT)

For continuous access to the registers at addresses of this controller beginning at A006 0004h, at least 67 ns must be secured.

To satisfy this restriction, control wait cycles using the frequency of CPU clock. The value after a reset is the maximum value (17 clock cycles), so select an appropriate value no greater than this.

This setting is the same as that for waiting in access to a FIFO port register. The maximum speeds of access to the FIFO ports are as follows:
MBW = 10b (32-bit width): Max 60 Mbytes/sec
MBW = 01b (16-bit width): Max 30 Mbytes/sec
MBW = 00b (8-bit width): Max 15 Mbytes/sec

32.2.1.3 System Configuration Status Register (SYSSTS0)

Address(es): A006 0004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	LNST[1:0]	
Value after hardware reset:	x	x	x	x	x	x	x	x	x	0	0	x	x	x	x	x
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b1, b0	LNST[1:0]	USB Data Line Status Monitor	Indicate the state of the USB line.	R	W
b15 to b2	—	Reserved	These bits are read as an undefined value.	R	—

Line Status Monitor Bits (LNST)

The states of USB data bus line of this controller is shown in Table 32.4. The controller monitors the states of USB data bus lines (D+ and D- lines) in the LNST bits of the SYSSTS0 register.
Reference to the LNST bits must be made following attach processing (DPRPU = 1) after USBE has been set to 1.

Table 32.4 States of USB Data Bus Line

LNST[1]	LNST[0]	Full-Speed Operations	High-Speed Operations	Chirp Operations*1
0	0	SE0	Squelch*2	Squelch*2
0	1	J state	Unsquelch*3	Chirp J*4
1	0	K state	Invalid	Chirp K*5
1	1	SE1	Invalid	Invalid

Note 1. Chirp: Reset handshake protocol being executed in high-speed operations enabled state (HSE = “1”)
Note 2. Squelch: SE0 or idle state
Note 3. Unsquelch: High-speed J state or high-speed K state
Note 4. Chirp J: Chirp J-state
Note 5. Chirp K: Chirp K-state

32.2.2 USB Signal Control

32.2.2.1 Device State Control Register 0 (DVSTCTR0)

Address(es): A006 0008h

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b2 to b0	RHST[2:0]	Reset Handshake	Indicate the state of reset handshake.	R	W
b7 to b3	—	Reserved	When writing to these bits, write 0.	R/W	—
b8	WKUP	Wakeup Output	Enables or disables the remote wakeup (resume signal output). Only 1 can be written to this bit. 0: Remote wakeup signal is not output. 1: Remote wakeup signal is output.	R/W	R/W
b15 to b9	—	Reserved	When writing to these bits, write 0.	R/W	—

Reset Handshake Status Bits (RHST)

These bits indicate the result of reset handshake. Table 32.5 lists the results of reset handshake.

Table 32.5 State of Reset Handshake

Bus State	RHST Bit Value
Powered or no connection	000b
Reset handshake in progress	100b
Full-speed connection	010b
High-speed connection	011b

When the HSE bit is set to 1, the RHST bits indicate 100b when this controller detects a USB bus reset. Then, these bits indicate 011b when this controller outputs Chirp-K and detects Chirp-JK from the USB host three times. If the connection speed is not fixed to high speed within 2.5 ms after Chirp-K output, these bits indicate 010b.

When the HSE bit is set to 0, these bits indicate 010b when the controller detects a USB bus reset.

A DVST interrupt is generated when the value of the RHST bits is 010b or 011b after the USB bus reset is detected by the controller.

Remote Wakeup (Resume Signal Output) Enable/Disable Bit (WKUP)

With the WKUP bit set to 1, this controller outputs the remote wakeup signal to the USB bus.
This controller controls the output time of a remote wakeup signal. When this bit is set to 1 by software, the controller clears this bit to 0 after outputting the 10-ms K-state.
According to the USB Specifications, the USB bus idle state must be kept for 5 ms or longer before a remote wakeup signal is sent. If this controller writes 1 to this bit right after detection of the suspended state, the K-state will be output after 2 ms.

Do not write 1 to this bit unless the device is in the suspended state (bits DVSQ = 1xxb) and the USB host enables the remote wakeup signal.
When this bit is set to 1, the internal clock must not be stopped even in the suspended state (write 1 to this bit while the SUSPM bit = 1).

32.2.3 Test Mode

32.2.3.1 USB Test Mode Register (TESTMODE)

Address(es): A006 000Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after hardware reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b3 to b0	UTST[3:0]	Test Mode	* See the detailed description below.	R/W	R
b15 to b4	—	Reserved	When writing to these bits, write 0.	R/W	—

Test Mode Bits (UTST)

Writing values to these bits allows this controller to output a USB test signal during high-speed operations. Table 32.6 shows the test mode operations of the controller.

Table 32.6 Test Mode Operations

Test Mode	UTST Settings
Normal operation	0000b
Test_J	0001b
Test_K	0010b
Test_SE0_NAK	0011b
Test_Packet	0100b
Test_Force_Enable	—
Reserved	0101b to 0111b

Write to these bits according to the SetFeature request from the USB host during high-speed communication.
This controller does not enter the suspended state while these bits are 0001h to 0100h.
To perform normal USB communications after the test mode is set, apply a hardware reset.

32.2.4 DMA-FIFO Bus Access Control

The D0FBCFG and D1FBCFG registers control bus access to DMA0-FIFO and DMA1-FIFO, respectively.

32.2.4.1 DMA0-FIFO Bus Configuration Register (D0FBCFG)
DMA1-FIFO Bus Configuration Register (D1FBCFG)

Address(es): D0FBCFG: A006 0010h
D1FBCFG: A006 0012h

b11 to b5	—	Reserved	When writing to these bits, write 0.	R/W	—
b13, b12	DFACC[1:0]	DMAx-FIFO Access Mode	Specify the access mode of the selected FIFO port. b13 b12 00: Cycle stealing mode (value after a reset) 01: 16-byte continuous access mode 10: 32-byte continuous access mode 11: Invalid	R/W	R
b15, b14	—	Reserved	When writing to these bits, write 0.	R/W	—

TENDx_N Input Signal Enable Bit (TENDE)

This bit selects enabling or disabling of the TEND input for write access to a FIFO buffer in DMA mode.
Set this bit to 0 when DFACC = 01b or 10b.

DMA Transfer FIFO Access Mode Select Bits (DFACC)

These bits specify the transfer mode for DMA transfer.

(a) When cycle stealing mode is set, use the DxFIFO port for access to the FIFO buffer.

(b) When 16- or 32-byte continuous access mode is set, use the DxFIFO continuous transfer port for access to the FIFO buffer. The MBW bits of DxFIFOSEL can only be set to 10b (32-bit width).

32.2.5 FIFO Ports

32.2.5.1 CFIFO Port Register (CFIFO)
D0FIFO Port Register (D0FIFO)
D1FIFO Port Register (D1FIFO)

Bit	Symbol	Bit Name	Description	S/W	H/W
b31 to b0	FIFOPORT [31:0]	FIFO Port	Accessing these bits allows reading the received data from the FIFO buffer or writing the transmit data to the FIFO buffer.	R/W	R/W

- FIFO port control

The transmission/reception buffer of this controller is made up of a FIFO structure (FIFO buffer). Use the FIFO port register for access to the FIFO buffer. There are three FIFO ports: CFIFO, D0FIFO, and D1FIFO ports. Also, there is a DxFIFO continuous transfer port for continuous transfer. Each FIFO port consists of a port register (CFIFO, D0FIFO, or D1FIFO) that handles reading of data from the FIFO buffer memory and writing of data to the FIFO buffer memory, a port select register (CFIFOSEL, D0FIFOSEL, or D1FIFOSEL) that is used to select the pipe assigned to the FIFO port, and a port control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR).

The FIFO ports have the following restrictions.

(1) Access to an FIFO buffer for DCP should be through the CFIFO port.
(2) Access to an FIFO buffer by DMA transfer when DFACC = 00b (cycle stealing mode) should be through the DxFIFO port.
(3) Access to an FIFO buffer by DMA transfer when DFACC = 01b or 10b (16-byte or 32-byte continuous access mode) should be through the DxFIFO continuous transfer port.
(4) The DxFIFO ports can also be accessed by the CPU.
(5) When using functions specific to the FIFO port, the pipe number (selected pipe) specified by the CURPIPE bits cannot be changed (when the DMA transfer function is used, etc.).
(6) Registers containing the FIFO port do not affect the other FIFO ports.
(7) Do not assign the same pipe to separate FIFO ports.
(8) In the FIFO buffer state, there are two types of access rights: one assigned to the CPU, and the other to SIE. Access from the CPU is not possible when SIE has the rights to access the FIFO buffer.

FIFO Port Bits (CFIFO, D0FIFO, and D1FIFO)

This controller accesses the FIFO buffer assigned to the pipe number written to the CURPIPE bits of the corresponding select registers (CFIFOSEL, D0FIFOSEL, and D1FIFOSEL) through access to any of these registers by software.

This register can only be accessed when the FRDY bit of each control register (CFIFOCTR, D0FIFOCTR, or D1FIFOCTR) indicates 1 (or while this controller asserts UCL_Dx_DREQ (interrupt sources [43] and [44]) output signals).
The valid bits of this register depend on the settings of the corresponding MBW and BIGEND bits.
Table 32.7 to Table 32.9 list the valid bits.

Table 32.7 Endian Operation in 32-Bit Access (MBW = 10)

BIGEND	b31 to b24	b23 to b16	b15 to b8	b7 to b0
0	N+3 address	N+2 address	N+1 address	N+0 address
1	N+0 address	N+1 address	N+2 address	N+3 address

Table 32.8 Endian Operation in 16-Bit Access (MBW = 01)

b13, b12	—	Reserved	When writing to these bits, write 0.	R/W	—
b14	REW	Buffer Pointer Rewind	Specifies 1 when rewinding the buffer pointer. This bit is read as 0. 0: The buffer pointer is not rewound. 1: The buffer pointer is rewound.	R/W	R
b15	RCNT	Read Count Mode	Specifies the read mode for the value in the DTLN bits in CFIFOCTR. 0: The DTLN bits are cleared when all of the received data has been read from the CFIFO. 1: The DTLN bits are decremented each time the received data is read from the CFIFO.	R/W	R

FIFO Port Access Pipe Specification Bits (CURPIPE)

Write the pipe number for the data to be read or written through the CFIFO port.

When modifying this bit field, write this bit first and then read this bit. Only when the written value matches the read one, proceed to the next process.

Do not specify the same pipe in the CURPIPE bits of the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Even if the setting of these bits is modified during access to the FIFO buffer, the state of the FIFO buffer is retained, with continued access proceeding after these bits are re-set to the value before the modification.

FIFO Port Access Direction Bit when DCP is Selected (ISEL)

To change this bit when the specified pipe is DCP, first write the data to this bit and then read it. Proceed to the next process after checking if the written value matches with the read value.

When the settings of this bit are modified during access to the FIFO buffer, access up to then is saved. Access to the buffer can be continued after rewriting the settings.

Settings in this bit should be made at the same as that of the CURPIPE bits.

FIFO Port Endian Control Bit (BIGEND)

In this bit, set the byte endian for the CFIFO port.
For details, see the description of FIFO Port Bits (CFIFO, D0FIFO, and D1FIFO).

CFIFO Port Access Bit Width Bits (MBW)

In this bit field, set the bit width for accessing the CFIFO port.

When the pipe specified in the CURPIPE bits is in the receiving direction, if reading is started after setting this bit field, do not modify the value of the MBW bits until all data is read.
When the specified pipe is in the receiving direction, modify the value of the CURPIPE bit once and then set the CURPIPE and MBW bits at the same time.
For the procedure for changing the CURPIPE bit, see the description for the same.

When the specified pipe is in the transmitting direction, to switch the bit width from 8 bits to 16 or 32 bits, or from 16 bits to 32 bits is not allowed while writing to the buffer memory is in progress.
With the 16-bit or 32-bit width setting, writing to odd bytes is possible by exercising byte access control.

Buffer Pointer Rewind (REW)

When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double-buffer operation, re-reading the currently-read FIFO buffer plane from the first data is allowed).

Do not set REW to 1 simultaneously with modifying the CURPIPE bits. Before setting REW to 1, be sure to check that FRDY is 1.

To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

Read Count Mode (RCNT)

When 0 is written to this bit, if all received data of the FIFO buffer assigned to the pipe specified in the CURPIPE bits (selected pipe) is read (when the data is read on one side of a double buffer), this controller clears the DTLN bits in the CFIFOCTR register to 0.

When 1 is written to this bit, the controller decrements the value of the DTLN bits in the CFIFOCTR register whenever the received data is read from the FIFO buffer assigned to the specified pipe.

32.2.5.3 D0FIFO Port Select Register (D0FIFOSEL)
D1FIFO Port Select Register (D1FIFOSEL)

b13	DCLRM	Auto Buffer Memory Clear Mode after Specified Pipe Data is Read	Enables or disables automatic clearing of the buffer memory after data has been read out using the selected pipe. 0: Auto buffer clear mode is disabled 1: Auto buffer clear mode is enabled	R/W	R
b14	REW	Buffer Pointer Rewind	Specifies 1 when rewinding the buffer pointer. This bit is read as 0. 0: The buffer pointer is not rewound 1: The buffer pointer is rewound	R/W	R
b15	RCNT	Read Count Mode	Specifies the read mode for the value in the DTLN bits in Dx_FIFOCTR. 0: The DTLN bits are cleared when all of the received data has been read. 1: The DTLN bits are decremented each time the received data is read.	R/W	R

FIFO Port Access Pipe Specification Bits (CURPIPE)

Write the pipe number for the data to be read or written through the DxFIFO port.

When modifying this bit field, first write a value to this bit field and then read it. Check if the write value matches the read value and then proceed to the next process.

Do not specify the same pipe in the CURPIPE bits of the CFIFOSEL, D0FIFOSEL, and D1FIFOSEL registers.

Even if the setting of these bits is modified during access to the FIFO buffer, the state of the FIFO buffer is retained, with continued access proceeding after these bits are re-set to the value before the modification.

DxFIFO Port Byte Endian Control Bit (BIGEND)

Write the byte endian for the DxFIFO port in this bit.
For details, see the description of FIFO Port Bits (CFIFO, D0FIFO, and D1FIFO).

DxFIFO Port Access Bit Width (MBW)

Write the bit width for accessing the DxFIFO port in this bit.

When the pipe specified in the CURPIPE bits is in the receiving direction, if reading is started after setting this bit field, do not modify the value of the MBW bits until all data is read.
When the specified pipe is in the receiving direction, set the CURPIPE and MBW bits at the same time.
For the procedure for changing the CURPIPE bit, see the description for the same.

For details, see the description of FIFO Port Access Pipe Specification Bits (CURPIPE).

UCL_Dx_DREQ Output Disable/Enable Bit (DREQE)

Use this bit to enable or disable the output of the UCL_Dx_DREQ signals.

When enabling the output of the UCL_Dx_DREQ signals, set this bit to 1 after setting the CURPIPE bits.

When modifying the setting of the CURPIPE bits, do so after setting this bit to 0.

Auto FIFO Buffer Clear Disable/Enable Bit (DCLRM)

After reading data in the specified pipe, disable or enable automatic clearing of the FIFO buffer. When 1 is written to this bit, this controller sets the BCLR bit to 1 for a FIFO buffer if a zero-length packet is received when the FIFO buffer assigned to the specified pipe is empty, or when a short packet is received and the data is completely read while BFRE = 1 .

When using this controller with the BRDYM bit set to 1, be sure to set this bit to 0.

Buffer Pointer Rewind (REW)

When the selected pipe is in the receiving direction, setting the REW bit to 1 while the FIFO buffer is being read allows re-reading the FIFO buffer from the first data (in double-buffer operation, re-reading the currently-read FIFO buffer plane from the first data is allowed).

Do not set the REW bit to 1 simultaneously with modifying the CURPIPE bits. Before setting the REW bit to 1, be sure to check that the FRDY bit is 1.
To re-write to the FIFO buffer again from the first data for the pipe in the transmitting direction, use the BCLR bit.

Read Count Mode (RCNT)

When 0 is written to this bit, if all received data of the FIFO buffer assigned to the pipe specified in the CURPIPE bits (selected pipe) is read (when the data is read on one side of a double buffer), this controller clears the DTLN bits in the DxFIFOCTR register to 0.

When 1 is written to this bit, the controller decrements the value of the DTLN bits in the DxFIFOCTR register whenever the received data is read from the FIFO buffer assigned to the specified pipe.

32.2.5.4 CFIFO Port Control Register (CFIFOCTR)
D0FIFO Port Control Register (D0FIFOCTR)
D1FIFO Port Control Register (D1FIFOCTR)

Address(es): CFIFOCTR: A006 0022h

Bit	Symbol	Bit Name	Description	S/W	H/W
b11 to b0	DTLN[11:0]	Receive Data Length	Indicate the length of the receive data.	R	W
b12	—	Reserved	When writing to this bit, write 0.	R/W	—
b13	FRDY	FIFO Port Ready	Indicates whether the FIFO port can be accessed. 0: FIFO port is not accessible. 1: FIFO port is accessible.	R	W
b14	BCLR	CPU Buffer Clear	Specifies 1 to clear the FIFO buffer on the CPU side for the selected pipe. Only 1 can be written to this bit. This bit is read as 0. 0: Invalid 1: Clears the CPU buffer memory on the CPU side.	R/W	R
b15	BVAL	Buffer Memory Valid Flag	Specifies 1 when writing has ended in the CPU-side FIFO buffer for the pipe specified in CURPIPE (selected pipe). Only 1 can be written to this bit. 0: Invalid 1: Writing ended	R/W	R/W

Receive Data Length Bits (DTLN)

The DTLN bits indicate the length of the receive data. While the FIFO buffer is being read, the DTLN bits indicate different values depending on the RCNT bit value as described below.

(1) When RCNT = 0:
The length of received data is set in these bits, and the value is retained until all received data has been read from a single FIFO buffer plane.
While BFRE is 1, these bits retain the length of the receive data until BCLR is set to 1 even after all data has been read.

(2) When RCNT = 1:
This controller decrements the value indicated by these bits each time data is read from the FIFO buffer.
(The value is decremented by 1 when MBW is 00, by 2 when MBW is 01b, and by 4 when MBW is 10b.)

This controller sets these bits to 0 when all data has been read from one FIFO buffer plane. However, in double-buffer operation, if data has been received in one FIFO buffer plane before all data has been read from the other plane, this controller sets these bits to indicate the length of the receive data in the latter plane when all data has been read from the former plane.

When reading these bits during FIFO buffer reading while RCNT = 1, note that these bits are updated within 150 ns after a read cycle for the FIFO port.

FIFO Port Ready Bit (FRDY)

This bit indicates whether the FIFO port can be accessed from the CPU (DMAC).

In the following cases, the controller sets FRDY to 1, but data cannot be read via the FIFO port because there is no data to be read. In these cases, set BCLR to 1, clear the FIFO buffer, and then enable transmission and reception of the next data.

(1) A zero-length packet is received when the FIFO buffer assigned to the selected pipe is empty.
(2) A short packet is received and the data is completely read while BFRE is 1.

CPU Buffer Clear Bit (BCLR)

When this bit is set to 1, this controller clears the FIFO buffer on the CPU for the selected pipe.

When double-buffer operation is set for the FIFO buffer assigned to the selected pipe, this controller clears only one plane of the FIFO buffer even when both planes are read-enabled.

When the selected pipe is the DCP, setting BCLR to 1 allows this controller to clear the FIFO buffer regardless of whether the FIFO buffer is on the CPU side or SIE side. When clearing the buffer on the SIE side, set the PID bits for the DCP to NAK before setting BCLR to 1.

When the selected pipe is not the DCP, writing 1 to this bit should be done while FRDY indicates 1. When checking the FRDY bit after executing BCLR, allow an interval of at least 80 ns after executing BCLR before referencing FRDY.

Buffer Memory Valid Flag (BVAL)

When the pipe specified in the CURPIPE bits (selected pipe) is for transmission, write 1 to this bit in the following cases. This controller sets the FIFO buffer from the CPU side to the SIE side, enabling transmission.

(1) To transmit the short packet, set this bit to 1 after data has been written.
(2) To transmit a zero-length packet, set this bit to 1 before writing data to FIFO.
(3) Set this bit to 1 after the number of data bytes has been written for the pipe in continuous transfer mode, where the number is a natural integral multiple of the maximum packet size and less than the buffer size.

When the data of the maximum packet size has been written for the pipe in non-continuous transfer mode, this controller sets this bit to 1 and switches the FIFO buffer from the CPU side to the SIE side, enabling transmission.

When 1 is written to the BVAL and BCLR bits at the same time when the specified pipe is in the transmitting direction, the controller clears the old data and enables the transmission of a zero-length packet.

Writing 1 to this bit should be done while FRDY indicates 1. When checking the FRDY bit after executing BVAL, allow an interval of at least 80 ns after executing BVAL before referencing FRDY.

When the specified pipe is in the receiving direction, do not write 1 to this bit.

32.2.6 Enabling Interrupts

32.2.6.1 Interrupt Enable Register 0 (INTENB0)

Address(es): A006 0030h

Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b9 to b0	PIPEBRDYE [9:0]	BRDY Interrupt Enable for Each Pipe	Enable or disable the BRDY interrupt for each pipe. 0: Interrupt output disabled 1: Interrupt output enabled	R/W	R
b15 to b10	—	Reserved	When writing to these bits, write 0.	R/W	—

Note: The bit number corresponds to the pipe number.

BRDY Interrupt Enable Bit for Each Pipe (PIPEBRDYE)

On detecting the BRDY interrupt for the pipe corresponding to the bit in this register which has been set to 1 by software, this controller sets 1 to the corresponding PIPEBRDY bit in BRDYSTS and the BRDY bit in INTSTS0, and asserts the interrupt signal through the INT_N (interrupt source [42]) pin.

While at least one PIPEBRDY bit in BRDYSTS indicates 1, this controller asserts the interrupt signal through the INT_N pin when the corresponding interrupt enable bit of this register is changed from 0 to 1 by software.

32.2.6.3 NRDY Interrupt Enable Register (NRDYENB)

Address(es): A006 0038h

Value after USB bus reset:	x	x	x	1	x	x	x	x	x	0	0	1	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b2 to b0	CTSQ[2:0]	Control Transfer Stage	Indicate the control transfer stage. b2 b0 000: Idle or setup stage 001: Control read data stage 010: Control read status stage 011: Control write data stage 100: Control write status stage 101: Control write (no data) status stage 110: Control transfer sequence error 111: Reserved	R	W
b3	VALID	USB Request Reception	Indicates whether reception of the USB request has been detected. When writing to this bit, only 0 can be written. 0: Not detected 1: Setup packet reception	R/W	W
b6 to b4	DVSQ[2:0]	Device State	Indicate the device state. b6 b4 000: Powered state 001: Default state 010: Address state 011: Configured state 1xx: Suspended state	R	W
b7	VBSTS	VBUS Input Status	Indicates the input state of the VBUS pin. 0: VBUS pin is at the low level 1: VBUS pin is at the high level	R	W
b8	BRDY	BRDY Interrupt Status	Indicates the BRDY interrupt state. 0: BRDY interrupts not generated 1: BRDY interrupts generated	R	W
b9	NRDY	NRDY Interrupt Status	Indicates the NRDY interrupt state. 0: NRDY interrupts not generated 1: NRDY interrupts generated	R	W
b10	BEMP	BEMP Interrupt Status	Indicates the BEMP interrupt state. 0: BEMP interrupts not generated 1: BEMP interrupts generated	R	W
b11	CTRT	Control Transfer Stage Transition Interrupt Status	Indicates the control transfer stage transition interrupt state. When writing to this bit, only 0 can be written. 0: Control transfer stage transition interrupts not generated 1: Control transfer stage transition interrupts generated	R/W	W
b12	DVST	Device State Transition Interrupt Status	Indicates the device state transition interrupt state. When writing to this bit, only 0 can be written. 0: Device state transition interrupts not generated 1: Device state transition interrupts generated	R/W	W

Bit	Symbol	Bit Name	Description	S/W	H/W
b13	SOFR	Frame Number Update Interrupt Status	Indicates the frame number update interrupt state. When writing to this bit, only 0 can be written. 0: SOF interrupts not generated 1: SOF interrupts generated	R/W	W
b14	RESM	Resume Interrupt Status	Indicates the resume detection interrupt state. When writing to this bit, only 0 can be written. 0: Resume interrupts not generated 1: Resume interrupts generated	R/W	W
b15	VBINT	VBUS Change Detect Interrupt Status	Indicates the VBUS change detection interrupt state. When writing to this bit, only 0 can be written. 0: VBUS interrupts not generated 1: VBUS interrupts generated	R/W	W

Note 1. To clear the state indicated by the VBINT, RESM, SOFR, DVST, or CTRT bits, write 0 only to the bit to be cleared, and write 1 to the other bits. Do not write 0 to the status bit set to 0.
Note 2. The controller detects the change in state indicated by the VBINT and RESM bits of this register, even while the clock is being stopped (SUSPM = 0), and conveys the interrupt if the corresponding interrupt is enabled. When the clock is enabled, clear the state using software.

Buffer Ready Interrupt Status Bit (BRDY)

This controller sets a BRDY bit to 1 when, among the PIPEBRDY bits for which the corresponding PIPEBRDYE bits in BRDYENB have been set to 1, at least one PIPEBRDY bit in BRDYSTS is set to 1 (that is, when this controller detects the BRDY interrupt state in at least one pipe among the pipes for which software has enabled the output of BRDY interrupts).

For the conditions for the setting of PIPEBRDY bits, refer to the description of the BRDYSTS register.

When a BRDY bit has been set to 1, the controller clears the bit in response to software writing 0 to all PIPEBRDY bits corresponding to PIPEBRDYE bits which have been set to 1.
A BRDY bit will not be cleared to 0 in response to software only writing 0 to individual bits that have been set to 1.

Buffer Not Ready Interrupt Status Bit (NRDY)

This controller sets an NRDY bit to 1 when, among the PIPEBRDY bits for which the corresponding PIPENRDYE bits in NRDYENB have been set to 1, at least one PIPENRDY bit in BNRDYSTS is set to 1 (that is, when this controller detects the NRDY interrupt state in at least one pipe among the pipes for which software has enabled the output of NRDY interrupts).

For the conditions for the setting of PIPENRDY bits, refer to the description of the NRDYSTS register.

When an NRDY bit has been set to 1, the controller clears the bit in response to software writing 0 to all PIPENRDY bits corresponding to PIPENRDYE bits which have been set to 1.
An NRDY bit will not be cleared to 0 in response to software only writing 0 to individual bits that have been set to 1.

Buffer Empty Interrupt Status Bit (BEMP)

This controller sets a BEMP bit to 1 when, among the PIPEBRDY bits for which the corresponding PIPEBEMPE bits in BEMPENB have been set to 1, at least one PIPEBEMP bit in BEMPSTS is set to 1 (that is, when this controller detects the BEMP interrupt state in at least one pipe among the pipes for which software has enabled the output of BEMP interrupts).

For the conditions for the setting of PIPEBEMP bits, refer to the description of the BEMPSTS register.

When a BEMP bit has been set to 1, the controller clears the bit in response to software writing 0 to all PIPEBEMP bits corresponding to PIPEBEMPE bits which have been set to 1.
A BEMP bit will not be cleared to 0 in response to software only writing 0 to individual bits that have been set to 1.

Control Transfer Stage Transition Interrupt Status Bit (CTRT)

If this controller detects the stage transition of control transfer, it updates the CTSQ value and sets 1 to this bit.

When this interrupt occurs, clear the state before the controller detects the next control transfer stage transition.

Device State Transition Interrupt Status Bit (DVST)

If this controller detects a change in the device state, it updates the DVSQ value and sets 1 to this bit.

When this interrupt occurs, clear the state before the controller detects the next device state transition.

Frame Number Update Interrupt Status Bit (SOFR)

The conditions when the controller sets 1 in this bit are below.
When updating the frame number, this controller sets 1 to this bit (this interrupt is detected every 1 ms).
The controller detects the SOFR interrupt by internal interpolation even if the SOF packet from the USB host is corrupted.

Resume Interrupt Status Bit (RESM)

If this controller is in the suspended state (DVSQ = 1xxb) and the DP pin falling edge is detected, 1 is set to this bit.

VBUS Change Interrupt Status Bit (VBINT)

When this controller detects a change in the VBUS pin input value (from high to low and from low to high), 1 is written to this bit. The controller writes the input value of the VBUS pin to the VBSTS bit. When the VBINT interrupt occurs, use the software to execute a consistency check several times during reading the VBSTS bit, and remove the chattering effect.

32.2.8.2 BRDY Interrupt Status Register (BRDYSTS)

Address(es): A006 0046h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b9 to b0	PIPEBRDY [9:0]	BRDY Interrupt Status for Each Pipe	Indicate the BRDY interrupt state for each pipe. When writing to these bits, only 0 can be written. 0: Interrupts not generated 1: Interrupts generated	R/W	W
b15 to b10	—	Reserved	When writing to these bits, write 0.	R/W	—

Note 1. The bit number corresponds to the pipe number.
Note 2. When BRDYM = 0, to clear the state of each bit of this register, write 0 only to the bit to be cleared and 1 to other bits.
Note 3. When BRDYM = 0, clearing these interrupt status bits should be done before accessing the FIFO.

BRDY Interrupt Status Bit for Each Pipe (PIPEBRDY)

When the BRDY interrupt is detected for a pipe by this controller, the controller sets 1 in the corresponding PIPEBRDY bit of the BRDYSTS register. Here, when 1 is written to the corresponding bit of BRDYENB register by using the software, the controller sets 1 to the BRDY bit of the INTSTS0 register.

The conditions for generating and clearing the BRDY interrupt depend on the settings of the SOFCFG.BRDYM bit and PIPECFG.BFRE bit for each pipe as described below.

- When BRDYM = 0 and BFRE = 0

With these settings, the BRDY interrupt indicates that the FIFO port is accessible.
On any of the following conditions, this controller generates the internal BRDY interrupt request trigger and sets 1 to the PIPEBRDY bit corresponding to the selected pipe.

(1) For the pipe in the transmitting direction
  (a) When the software has modified the DIR bit from 0 to 1
  (b) When the controller ends the packet transmission of the selected pipe in the condition where writing is not possible from the CPU to the FIFO buffer that has been assigned to the selected pipe (when the BSTS bit is read as 0).
  In continuous transmission/reception mode, the request trigger is generated when data of one plane of the FIFO buffer is complete.
  (c) In double-buffer operation, one FIFO buffer being empty on completion of the writing of data to the other FIFO buffer.
  The request trigger is not generated until completion of writing data to the currently-written FIFO buffer plane even if transmission to the other FIFO buffer is completed.
  (d) When the hardware flushes the buffer of the pipe for isochronous transfers.

(e) The FIFO buffer making the transition from the write-disabled to the write-enabled state in response to writing of 1 to the ACLRM bit.
The request trigger is not generated for the DCP (that is, during data transmission for control transfers).

(2) For the pipe in the receiving direction

(a) When packet reception is completed successfully thus enabling the FIFO buffer to be read when read-access from the CPU to the FIFO buffer for the selected pipe is disabled (when the BSTS bit is read as 0).
The request trigger is not generated for the transaction in which DATA-PID disagreement occurs.
When a short packet is received, the request trigger is generated even if the FIFO buffer has available space.
When the transaction counter is used, the request trigger is generated on receiving the specified number of packets.
In this case, the request trigger is generated even if the FIFO buffer has available space.

(b) In double-buffer operation, one FIFO buffer being ready for reading on completion of the reading of data from the other FIFO buffer.
The request trigger is not generated until completion of reading data from the currently-read FIFO buffer plane even if reception by the other FIFO buffer is completed.
The BRDY interrupt is not generated in the status stage of control transfers.
The PIPEBRDY interrupt state of the selected pipe can be cleared to 0 by writing 0 to the corresponding PIPEBRDY interrupt status bit in the BRDYSTS register. In this case, 1s should be written to the PIPEBRDY interrupt status bits for the other pipes.
Be sure to clear the BRDY state before accessing the FIFO buffer.

- When BRDYM = 0 and BFRE = 1

With these settings, this controller generates the BRDY interrupt on completion of the reading of all data for a single transfer using the pipe in the receiving direction, and sets 1 to the PIPEBRDY bit corresponding to the selected pipe.

On any of the following conditions, this controller determines that the last data for a single transfer has been received.

(1) When a short packet including a zero-length packet is received.

(2) When the transaction counter register (TRNCNT bits) is used and the number of packets specified by the TRNCNT bits is completely received.

When the pertinent data is completely read out after any of the above determination conditions has been satisfied, this controller determines that all data for a single transfer has been completely read out.

When a zero-length packet is received when the FIFO buffer is empty, the controller determines that all data for a single transfer has been completely read out upon the FRDY and the DTLN bits of the FIFO port control register are set to 1 and 0, respectively.
In this case, write 1 to the BCLR bit of the corresponding FIFOCTR register by software to start the next transfer.

With these settings, this controller does not detect the BRDY interrupt for the pipe in the transmitting direction.

The PIPEBRDY interrupt state of the selected pipe can be cleared to 0 by writing 0 to the corresponding PIPEBRDY interrupt status bit. In this case, 1s should be written to the PIPEBRDY interrupt status bits for the other pipes.

In this mode, the BFRE bit setting should not be modified until all data for a single transfer has been processed.
When it is necessary to modify the BFRE bit before completion of processing, all the FIFO buffers for the selected pipe should be cleared using the ACLRM bit.

- When BRDYM = 1 and BFRE = 0

With these settings, the PIPEBRDY values are linked to the BSTS bit settings for each pipe. In other words, the BRDY interrupt status bits (PIPEBRDY) are set to 1 or 0 by this controller depending on the FIFO buffer state.

(1) For the pipe in the transmitting direction
The setting of a BRDY interrupt status bit is 1 while the port register of the corresponding FIFO buffer is ready for written data and 0 when it is not able to accept written data.
However, the BRDY interrupt is not generated in response to setting of the bit to 1 if writing to the DCP in the transmitting direction can proceed.

(2) For the pipe in the receiving direction
The setting of a BRDY interrupt status bit is 1 while the port register of the FIFO buffer is ready for reading and 0 when all data have been read.

When a zero-length packet is received when the FIFO buffer is empty, the corresponding bit is set to 1 and the BRDY interrupt continues to be effective until 1 is written to BCLR.

With this setting, the PIPEBRDY bit cannot be cleared to 0.

When BRDYM is set to 1, all of the BFRE bits (for all pipes) should be cleared to 0.
When BRDYM is set to 1, the INTL bit should be set to 1 (level control).

32.2.8.3 NRDY Interrupt Status Register (NRDYSTS)

Address(es): A006 0048h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b9 to b0	PIPENRDY [9:0]	NRDY Interrupt Status for Each Pipe	Indicate the NRDY interrupt state for each pipe. When writing to these bits, only 0 can be written. 0: Interrupts not generated 1: Interrupts generated	R/W	W
b15 to b10	—	Reserved	When writing to these bits, write 0.	R/W	—

Note 1. The bit number corresponds to the pipe number.
Note 2. To clear the state indicated by each bit of this register, write 0 only to the bit to be cleared and 1 to the other bits.

NRDY Interrupt Status Bit for Each Pipe (PIPENRDY)

On generating the internal NRDY interrupt request for the pipe whose PID bits are set to BUF, this controller sets the corresponding PIPENRDY bit in NRDYSTS in the register to 1. If the corresponding bit in the NRDYENB register is set to 1, this controller sets the NRDY bit in INTSTS0 in the register to 1.
The conditions on which this controller generates the internal NRDY interrupt request for a given pipe are described below.
However, the internal NRDY interrupt request is not generated during status stage execution of the control transfer.

(1) When the pipe is in the transmitting direction
  (a) When an IN Token is received while there is no transmission data in the FIFO buffer and the corresponding PIPE PID bit is set to BUF (01):
  In this case, this controller generates an NRDY interrupt request at the reception of the IN token, setting the PIPENRDY bit to 1.
  For the pipe for the isochronous transfers in which an interrupt is generated, this controller transmits a zero-length packet, setting the OVRN bit to 1.

(2) For the pipe in the receiving direction

(a) When the PID bits for the corresponding pipe are set to BUF (01) and an OUT token is received while there is no open space in the FIFO buffer:
For the pipe for the isochronous transfers in which an interrupt is generated, this controller generates an NRDY interrupt request at the reception of the OUT token, setting the PIPENRDY bit to 1 and OVRN bit to 1.
For the pipe for the transfers other than isochronous transfers in which an interrupt is generated, this controller generates an NRDY interrupt request when an NAK handshake is transferred after the data following the OUT token was received, setting the PIPENRDY bit to 1.
However, during re-transmission (due to DATA-PID disagreement), the NRDY interrupt request is not generated. In addition, if an error occurs in the DATA packet, the NRDY interrupt request is not generated.

(b) When the PID bits for the corresponding pipe are set to BUF (01) and a PING token is received while there is no open space in the FIFO buffer:
In this case, this controller generates an NRDY interrupt request at the reception of the PING token, setting the PIPENRDY bit to 1.

(c) In an isochronous transfer pipe, when the PID bits are set to BUF (01) and data is not received successfully within the interval frame:
In this case, this controller generates an NRDY interrupt request at the reception of an SOF, and sets the PIPENRDY bit to 1.

32.2.8.4 BEMP Interrupt Status Register (BEMPSTS)

Address(es): A006 004Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	PIPEBEMP[9:0]

Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b9 to b0	PIPEBEMP [9:0]	BEMP Interrupt Status for Each Pipe	Indicate the BEMP interrupt state for each pipe. When writing to these bits, only 0 can be written. 0: Interrupts not generated 1: Interrupts generated	R/W	W
b15 to b10	—	Reserved	When writing to these bits, write 0.	R/W	—

Note 1. The bit number corresponds to the pipe number.
Note 2. To clear the state indicated by each bit of this register, write 0 only to the bit to be cleared and 1 to the other bits.

BEMP Interrupt Status Bit for Each Pipe (PIPEBEMP)

On detecting the BEMP interrupt for the pipe whose PID bits are set to BUF by software, this controller sets the corresponding PIPEBEMP bit in BEMPSTS to 1. If the corresponding bit in BEMPENB is set to 1 by software, this controller sets the BEMP bit in INTSTS0 to 1.

The following describes the conditions on which this controller generates the internal BEMP interrupt request.

(1) For the pipe in the transmitting direction, when the FIFO buffer of the corresponding pipe is empty on completion of transmission (including zero-length packet transmission).
In single-buffer operation, the internal BEMP interrupt request is generated simultaneously with the BRDY interrupt for the pipe other than DCP.
However, the internal BEMP interrupt request is not generated on any of the following conditions.
  (a) When writing data to the FIFO buffer on the CPU (DMAC) side is started by software on completion of transmitting data of one plane in double-buffer operation.
  (b) When the buffer is cleared (emptied) by setting the ACLRM or BCLR bit to 1.
  (c) When IN transfer (zero-length packet transmission) is performed during the control transfer status stage.

(2) For the pipe in the receiving direction
When the successfully-received data packet size exceeds the specified maximum packet size.
In this case, this controller generates the BEMP interrupt request, setting the corresponding PIPEBEMP bit to 1, and discards the received data and modifies the setting of the PID bits of the corresponding pipe to STALL (11).
However, the internal BEMP interrupt request is not generated on any of the following conditions.
  (a) When a CRC error or bit stuffing error is detected in the received data.
  (b) When a setup transaction is being performed.

Writing 0 to the PIPEBEMP bit clears the state; writing 1 to the PIPEBEMP bit has no effect.

32.2.9 Frame Number Registers

32.2.9.1 Frame Number Register (FRMNUM)

Address(es): A006 004Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OVRN	CRCE	—	—	—	FRNM[10:0]										
Value after hardware reset:	0	0	x	x	x	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b10 to b0	FRNM[10:0]	Frame Number	Indicate the latest frame number.	R	W
b13 to b11	—	Reserved	When writing to these bits, write 0.	R/W	—
b14	CRCE	CRC Error Detection Status	Indicates whether a CRC error has been detected in the pipe during isochronous transfer. When writing to this bit, only 0 can be written. 0: No error 1: An error occurred.	R/W	W
b15	OVRN	Overrun/Underrun Detection Status	Indicates whether an overrun/underrun error has been detected in the pipe during isochronous transfer. When writing to this bit, only 0 can be written. 0: No error 1: An error occurred.	R/W	W

Note 1. The OVRN bit is for use in debugging. When designing a system, control the timing so that neither overrun nor underrun occurs.

Frame Number Bits (FRNM)

This controller sets these bits to indicate the latest frame number, which is updated every time an SOF packet is issued or received (every 1 ms).

When reading these bits by software, repeat reading until the same value is read twice.

CRC Error Detection Status Bit (CRCE)

In an isochronous transfer pipe, this controller sets 1 to this bit when a CRC error or bit stuffing error has been detected.

This bit can be cleared by writing 0 to it by software. In this case, write 80h when OVRN is not to be cleared at the same time.

This controller generates an internal NRDY interrupt request when it detects a CRC error. For details, see NRDY Interrupt Enable Bit for Each Pipe (PIPENRDYE).

Overrun/Underrun Detection Status Bit (OVRN)

For the isochronous transfer pipe, this controller sets 1 to this bit when an overrun/underrun is detected.
When an overrun/underrun is detected, the controller issues an internal NRDY request. Refer to NRDY Interrupt Enable Bit for Each Pipe (PIPENRDYE) for details.

This bit can be cleared writing 0 to it by software. In this case, write 40h when CRCE is not to be cleared at the same time.

This controller sets this bit to 1 on any of the following conditions.

(1) For the isochronous transfer pipe in the transmitting direction, the IN token is received before all the transmit data has been written to the FIFO buffer.
(2) For the isochronous transfer pipe in the receiving direction, the OUT token is received when no FIFO buffer planes are empty.

32.2.9.2 µFrame Number Register (UFRMNUM)

Address(es): A006 004Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	UFRNM[2:0]		
Value after hardware reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b2 to b0	UFRNM[2:0]	Microframe Number	Indicate the µframe number.	R	W
b15 to b3	—	Reserved	These bits are read as an undefined value.	R	—

Microframe Number Bits (UFRNM)

This controller sets these bits to indicate the µframe number during high-speed operation. During operation other than high-speed operation, this controller sets these bits to 00h.

When reading these bits, repeat reading until the same value is read twice.

32.2.10 USB Address

32.2.10.1 USB Address Register (USBADDR)

Address(es): A006 0050h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	USBADDR[6:0]						
Value after hardware reset:	x	x	x	x	x	x	x	x	x	0	0	0	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b6 to b0	USBADDR [6:0]	USB Address	Indicate the USB address assigned by the host.	R	R/W
b15 to b7	—	Reserved	These bits are read as an undefined value.	R	—

USB Address Bits (USBADDR)

These bits indicate the USB address assigned by the host when the SetAddress request is successfully processed.
If a USB bus reset is detected by the controller, 00h is set to this bit.

32.2.11 USB Request Registers

The USB request registers are used to store the setup requests for control transfers. The values of the USB request that have been received are stored.

32.2.11.1 USB Request Type Register (USBREQ)

Address(es): A006 0054h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	bRequest[7:0]								bmRequestType[7:0]							
Value after hardware reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b7 to b0	bmRequestType [7:0]	Request Type	USB request bmRequestType value	R	W
b15 to b8	bRequest[7:0]	Request	USB request bRequest value	R	W

USB Request Type Bits (bmRequestType)

These bits indicate the USB request data value received by this controller in the setup transaction. Writing to these bits by software has no effect.

USB Request Bits (bRequest)

These bits indicate the USB request data value received by this controller in the setup transaction. Writing to these bits by software has no effect.

32.2.11.2 USB Request Value Register (USBVAL)

Address(es): A006 0056h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	wValue[15:0]															
Value after hardware reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b15 to b0	wValue[15:0]	Value	USB request wValue value	R	W

Value Bits (wValue)

These bits are used to read the value of the USB request wValue. Bits 7 to 0 are lower-order byte.

These bits indicate the USB request wValue value received by this controller in the setup transaction. Writing to these bits by software has no effect.

32.2.11.3 USB Request Index Register (USBINDX)

Address(es): A006 0058h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	wIndex[15:0]															
Value after hardware reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b15 to b0	wIndex[15:0]	Index	USB request wIndex value	R	W

Index Bits (wIndex)

These bits are used to read the value of the USB request wIndex. Bits 7 to 0 are lower-order byte.

These bits indicate the USB request wIndex value received by this controller in the setup transaction. Writing to these bits by software has no effect.

32.2.11.4 USB Request Length Register (USBLENG)

Address(es): A006 005Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	wLength[15:0]															
Value after hardware reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b15 to b0	wLength [15:0]	Length	USB request wLength value	R	W

Length Bit (wLength)

These bits are used to read the value of the USB request wLength. Bits 7 to 0 are lower-order byte.

These bits indicate the USB request wLength value received in setup transaction by the controller. Writing to these bits by software has no effect.

32.2.12 DCP Configuration

32.2.12.1 DCP Maximum Packet Size Register (DCPMAXP)

Address(es): A006 005Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	MXPS[6:0]						
Value after hardware reset:	0	0	0	0	x	x	x	x	x	1	0	0	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b6 to b0	MXPS[6:0]	Maximum Packet Size	Specify the maximum data payload (maximum packet size) for the DCP.	R	R/W
b15 to b7	—	Reserved	These bits are read as an undefined value.	R	—

Maximum Packet Size Bits (MXPS)

Set the maximum data payload (maximum packet size) for the DCP in these bits. 40h (64 bytes) is the value after a reset.

The MXPS bits should be set to the value based on the USB specification.
The MXPS bits should be set while PID = NAK and before setting the CURPIPE bits.
Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

While MXPS is 0, do not write to the FIFO buffer or do not set PID to BUF.

32.2.12.2 DCP Control Register (DCPCTR)

Address(es): A006 0060h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	BSTS	—	—	—	—	—	—	SQCLR	SQSET	SQMON	PBUSY	—	—	CCPL	PID[1:0]	
Value after hardware reset:	0	0	0	0	0	x	x	0	0	1	0	0	x	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b1, b0	PID[1:0]	Response PID	These bits control the response type of this controller during control transfer. b1 b0 00: NAK response 01: BUF response (depending on the buffer state) 10: STALL response 11: STALL response	R/W	R/W
b2	CCPL	Control Transfer End Enable	Setting this bit to 1 enables the status stage of the control transfer to be completed. 0: End of the control transfer disabled 1: End of the control transfer enabled	R/W	R/W
b4, b3	—	Reserved	When writing to these bits, write 0.	R/W	—
b5	PBUSY	PIPE Busy	Indicates whether the selected pipe is currently being used by the USB bus. 0: The pipe is not being used by the USB bus. 1: The pipe is being used by the USB bus.	R	W
b6	SQMON	Sequence Toggle Bit Monitor	Indicates the expected value of the sequence toggle bit for the next transaction during the DCP transfer. 0: DATA0 1: DATA1	R	W
b7	SQSET	Toggle Bit Set	Specifies DATA1 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect 1: Specifies DATA1	R/W	R
b8	SQCLR	Toggle Bit Clear	Specifies DATA0 as the expected value of the sequence toggle bit for the next transaction during the DCP transfer. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect 1: Specifies DATA0	R/W	R
b10, b9	—	Reserved	When writing to these bits, write 0.	R/W	—
b11			When writing to this bit, write 1. However, this bit is read as 0.	R/W	—
b12			When writing to this bit, write 0.	R/W	—
b14, b13			When writing to these bits, write 1. However, these bits are read as 0.	R/W	—
b15	BSTS	Buffer Status	Indicates whether access to the DCP FIFO buffer is enabled or disabled. 0: Buffer access disabled 1: Buffer access enabled	R	W

Response PID Bits (PID)

Change the setting of these bits from NAK to BUF by software during data stage or status stage of control transfers.

This controller changes the setting of these bits in the following conditions:

(1) This controller changes the setting of the PID bits to select NAK response (00) on receiving the setup packet. Here, this controller sets VALID to 1. The setting of the PID bits cannot be changed until VALID is set to 0.
(2) This controller sets the PID bits to select STALL response (11) on receiving the data of the size exceeding the maximum packet size when the PID bits have been set to select BUF response.
(3) This controller sets the PID bits to select STALL response (1x) on detecting the control transfer sequence error.
(4) This controller sets the PID bits to select NAK response on detecting the USB bus reset.

This controller does not reference to the setting of the PID bits while the SET_ADDRESS request is processed (auto processing).

Control Transfer End Enable Bit (CCPL)

Setting this bit to 1 while the corresponding PID bits are set to BUF enables the stage of the control transfer to be completed.
Specifically, during control read transfer, this controller transmits the ACK handshake in response to the OUT transaction from the USB host, and outputs the zero-length packet in response to the IN transaction from the USB host during control writing or no-data control transfer. However, on detecting the SET_ADDRESS request, this controller operates in auto response mode from the setup stage up to the status stage completion irrespective of the setting of this bit.

This controller modifies this bit from 1 to 0 on receiving the new setup packet.

1 cannot be written by software to this bit while VALID is 1.

PIPE Busy Bit (PBUSY)

This controller modifies this bit from 0 to 1 upon start of the USB transaction for the selected pipe, and modifies the bit from 1 to 0 upon completion of one transaction.

Reading this bit after the PID bits have been set to NAK allows checking that modification of the pipe settings is possible.

Sequence Toggle Bit Monitor Bit (SQMON)

This bit indicates the expected value of the sequence toggle bit of the selected pipe.

This bit is toggled upon normal completion of the transaction. However, this bit is not toggled when a DATA-PID disagreement occurs during the receiving transfer.

This controller sets this bit to 1 (specifies DATA1 as the expected value) upon normal reception of the setup packet. This controller does not reference to this bit during the IN/OUT transaction of the status stage, and does not allow this bit to toggle upon normal completion.

Sequence Toggle Bit Set Bit (SQSET)

Setting this bit to 1 by software allows this controller to set DATA1 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

Set this bit to 1 while PID is NAK and before setting the CURPIPE bits.
Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY is 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Clear Bit of Sequence Toggle Bit (SQCLR)

Setting this bit to 1 by software allows this controller to set DATA0 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Do not set the SQCLR and SQSET bits to 1 simultaneously.

Set this bit to 1 while PID is NAK and before setting the CURPIPE bits.
Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Buffer Status Bit (BSTS)

This bit indicates whether access from the CPU to the FIFO buffer assigned to the DCP is possible.
The meaning of the BSTS bit depends on the ISEL bit setting as follows.

(1) When ISEL = 0: indicates whether the received data can be read from the buffer.
(2) When ISEL = 1: indicates whether the data for transmission can be written to the buffer.

32.2.13 Pipe Configuration Register

Pipes 1 to 9 should be set using the PIPESEL, PIPECFG, PIPEBUF, PIPEMAXP, PIPEPERI, PIPExCTR, PIPExTRE and PIPExTRN registers.

After selecting the pipe using the PIPESEL register, functions of the pipe should be set using the PIPECFG, PIPEBUF, PIPEMAXP and PIPEPERI registers. The PIPExCTR, PIPExTRE and PIPExTRN registers can be set regardless of the pipe selection in the PIPESEL register.

32.2.13.1 Pipe Window Select Register (PIPESEL)

Address(es): A006 0064h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	PIPESEL[3:0]			
Value after hardware reset:	x	x	x	x	x	x	x	x	x	x	x	x	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b3 to b0	PIPESEL [3:0]	Pipe Window Select	Specify the pipe corresponding to the registers allocated at address ranges from 68H to 6EH. b3 b0 0000: No pipe selected 0001: Pipe 1 0010: Pipe 2 0011: Pipe 3 0100: Pipe 4 0101: Pipe 5 0110: Pipe 6 0111: Pipe 7 1000: Pipe 8 1001: Pipe 9	R/W	R
b15 to b4	—	Reserved	When writing to these bits, write 0.	R/W	—

Note 1. When 0000b is set in PIPESEL, 0 is read from all of the bits in the PIPECFG, PIPEBUF, PIPEMAXP, and PIPEPERI registers. When 0000b is set in PIPESEL, writing to the bits in these registers (at address ranges from 68H to 6EH) has no effect.

Pipe Window Select Bits (PIPESEL)

When a value between 0001b and 1001b is set in these bits, the information and settings for the corresponding pipe can be read from the registers at address ranges from A006 0068h to A006 006Eh. After a pipe is specified by setting these bits, the values set by software to the registers at address ranges from A006 0068h to A006 006Eh are reflected in the corresponding pipe transfer type by this controller.

When 0000b is set in PIPESEL, 0 is read from all of the bits from the registers at address ranges from A006 0068h to A006 006Eh. When 0000b is set in PIPESEL, writing to the bits in these registers has no effect.

32.2.13.2 Pipe Configuration Register (PIPECFG)

Address(es): A006 0068h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b3 to b0	EPNUM[3:0]	Endpoint Number	Specify endpoint number for the selected pipe.	R/W	R
b4	DIR	Transfer Direction	Specifies pipe transfer direction for the selected pipe. 0: Receiving direction 1: Transmitting direction	R/W	R
b6, b5	—	Reserved	When writing to these bits, write 0.	R/W	—
b7	SHTNAK	Pipe Disable at the End of Transfer	Specifies whether to change PID to NAK at the end of transfer when the selected pipe is in the receiving direction. 0: Pipe continued at end of transfer 1: Pipe disabled at end of transfer	R/W	R
b8	CNTMD	Continuous Transfer Mode	Specifies whether to use the selected pipe in continuous transfer mode. 0: Non-continuous transfer mode 1: Continuous transfer mode	R/W	R
b9	DBLB	Double Buffer Mode	Selects either single- or double-buffer operation for the FIFO buffer used by the selected pipe. 0: Single-buffer operation 1: Double-buffer operation	R/W	R
b10	BFRE	BRDY Interrupt Operation Specification	Specifies the BRDY interrupt generation timing from this controller to the CPU with respect to the selected pipe. 0: BRDY interrupt notification upon transmitting or receiving data 1: BRDY interrupt notification upon reading data	R/W	R
b13 to b11	—	Reserved	When writing to these bits, write 0.	R/W	—
b15, b14	TYPE[1:0]	Transfer Type	Specify the transfer type for the pipe selected by the PIPESEL bits (selected pipe). b15 b14 00: Pipe is not in use. 01: Bulk transfer 10: Interrupt transfer 11: Isochronous transfer	R/W	R

Endpoint Number Bits (EPNUM)

Specify the endpoint number for the selected pipe in these bits by software.
Setting 0000b indicates that the pipe is not being used.

These bits should be modified while PID is NAK, and the pipe is not selected by the CURPIPE bits.

Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Do not make the settings such that the combination of the set values in the DIR and EPNUM bits should be the same for two or more pipes (EPNUM = 0000b (the selected pipe is not in use) can be set for all the pipes).

Transfer Direction Bit (DIR)

When this bit is set to 0 by software, this controller uses the selected pipe in the receiving direction, and when this bit is set to 1, this controller uses the selected pipe in the transmitting direction.

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.
To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the above-described state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Pipe Disable Bit at the End of Transfer (SHTNAK)

This bit is valid when pipes 1 to 5 are selected in the receiving direction.
When this bit is set to 1 for the selected pipe in the receiving direction, this controller modifies the PID bits for the selected pipe to NAK on determining the end of the transfer. This controller determines that the transfer has ended on any of the following conditions.

(1) A short packet (including a zero-length packet) is successfully received.
(2) The transaction counter is used and the number of packets specified for the counter is successfully received.

This bit should be modified while PID is NAK.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

This bit should be cleared to 0 for the pipe in the transmitting direction.

Continuous Transfer Mode Bit (CNTMD)

This bit is valid when pipes 1 to 5 are selected and the transfer type of the selected pipe is set to bulk.

According to the setting value of this bit, this controller determines transmission/reception completion for the FIFO buffer assigned to the selected pipe. See Table 32.10.

Table 32.10 Relationship between Transfer Mode Settings by CNTMD Bit and Timings at which Reading Data or Transmitting Data from FIFO Buffer is Enabled

CNTMD Bit Setting	When Reading Data or Transmitting Data is Enabled
0	In the receiving direction (DIR = 0), the FIFO buffer is ready for reading in the following case. This controller receives one packet.
	In the transmitting direction (DIR = 1), the FIFO buffer is ready for transmission in either of the following cases. (1) Data of the maximum packet size is written to the FIFO buffer by software (or DMAC). (2) Data of the short packet size (including 0-byte data) is written to the FIFO buffer and then 1 is written to BVAL by software (or DMAC).
1	In the receiving direction (DIR = 0), the FIFO buffer is ready for reading in any of the following cases. (1) The number of the data bytes received in the FIFO buffer assigned to the selected pipe is equal to the number of assigned data bytes ((BUFSIZE + 1) × 64). (2) This controller receives a short packet other than a zero-length packet. (3) This controller receives a zero-length packet when data is already stored in the FIFO buffer assigned to the selected pipe. (4) This controller receives the number of packets equal to the transaction counter value specified for the selected pipe by software.
	In the transmitting direction (DIR = 1), the FIFO buffer is ready for transmission in any of the following cases (1) to (3). (1) The number of the data bytes written to the FIFO buffer by software (or DMAC) is equal to the number of data bytes in a single FIFO buffer plane assigned to the selected pipe. (2) The number of data bytes less than the size of a single FIFO buffer plane (including 0-byte data) assigned to the selected pipe is written to the FIFO buffer and then 1 is written to BVAL by software (or DMAC) . (3) The number of data bytes less than the size of a single FIFO buffer plane (including 0-byte data) assigned to the selected pipe is written to the FIFO buffer and then the DENDx_N signal is asserted at the same time as writing the last data by software (or DMAC).

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.
To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the above-described state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Double Buffer Mode Bit (DBLB)

This bit is valid when pipes 1 to 5 are selected.

When this bit is set to 1, this controller assigns two planes of the FIFO buffer size specified by the BUFSIZE bits in PIPEBUF to the selected pipe.
Specifically, the following expression determines the FIFO buffer size assigned to the selected pipe by this controller.
(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.
To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously by software to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the above-described state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

BRDY Interrupt Operation Specification Bit (BFRE)

This bit is valid when pipes 1 to 5 are selected.

When this bit is set to 1 and the selected pipe is in the receiving direction (the DIR bit is set to 0), this controller detects the transfer completion and generates the BRDY interrupt on having read the pertinent packet.
When the BRDY interrupt is generated with the above conditions, 1 must be written to BCLR. The FIFO buffer assigned to the selected pipe is not enabled for reception until 1 is written to BCLR.

When this bit is set to 1 and the selected pipe is in the transmitting direction (the DIR bit is set to 1), this controller does not generate the BRDY interrupt. For details, refer to the description of the PIPEBRDY interrupt register.

This bit should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.
To modify this bit after completing USB communication using the selected pipe, write 1 and then 0 to ACLRM continuously to clear the FIFO buffer assigned to the selected pipe while the PID and CURPIPE bits are in the above-described state.

Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Transfer Type Bits (TYPE)

Specify the USB transfer type for the pipe selected by the PIPESEL bits (selected pipe) in the TYPE bits.
Table 32.11 lists the selected pipes and transfer types that can be set in the TYPE bits.

Table 32.11 Selected Pipes and Transfer Types that can be Set in TYPE Bits

Selected Pipe	TYPE Bits	USB Transfer Type
Pipe 1 or Pipe 2	01b or 11b	Bulk or isochronous transfer
Pipe 3 to Pipe 5	01b	Bulk transfer
Pipe 6 to Pipe 9	10b	Interrupt transfer

Before setting PID to BUF for the selected pipe (before starting USB communication using the selected pipe), be sure to set these bits to the value other than 00b.

These bits should be modified while the PID bits for the selected pipe are set to NAK. Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY is 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

32.2.13.3 Pipe Buffer Specification Register (PIPEBUF)

Address(es): A006 006Ah

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	BUFSIZE[4:0]					—	—	BUFNMB[7:0]							
Value after hardware reset:	x	0	0	0	0	0	x	x	0	0	0	0	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b7 to b0	BUFNMB[7:0]	Buffer number	Specify the pipe FIFO buffer number for the selected pipe. (4h to 80h)	R/W	R
b9, b8	—	Reserved	When writing to these bits, write 0.	R/W	—
b14 to b10	BUFSIZE[4:0]	Buffer size	Specify the FIFO buffer size for the pipe specified in PIPESEL bits (selected pipe). 00h: 64 bytes 01h: 128 bytes | 1Fh: 2 Kbytes	R/W	R
b15	—	Reserved	When writing to this bit, write 0.	R/W	—

Note 1. The bits in this register should be modified while PID is NAK and the pipe is not selected by the CURPIPE bits.
Note 2. Before modifying the bits of this register after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Buffer Number Bits (BUFNMB)

The first block number in the FIFO buffer to be allocated for the selected pipe should be set in these bits. The FIFO buffer blocks allocated for the selected pipe by this controller are determined as follows:
Block number: BUFNMB to block number of BUFNMB + (BUFSIZE + 1) × (DBLB + 1) - 1

These bits must be set to a value that does not exceed the size of installed memory (0 [00h] to 8192 [0x80] for 8-Kbyte memory). Observe the following conditions:
00h is used exclusively for DCP.
04h is used exclusively for pipe 6. However, when pipe 6 is not used, 04h can be used for other pipes. When pipe 6 is selected, writing to these bits has no effect and 04h is automatically assigned by this controller.
05h is used exclusively for pipe 7. However, when pipe 7 is not used, 05h can be used for other pipes. When pipe 7 is selected, writing to these bits has no effect and 05h is automatically assigned by this controller.
06h is used exclusively for pipe 8. However, when pipe 8 is not used, 06h can be used for other pipes. When pipe 8 is selected, writing to these bits has no effect and 06h is automatically assigned by this controller.
07h is used exclusively for pipe 9. However, when pipe 9 is not used, 07h can be used for other pipes. When pipe 9 is selected, writing to these bits has no effect and 07h is automatically assigned by this controller.

Buffer Size Bits (BUFSIZE)

Specify the size of the FIFO buffer for the selected pipe in these bits in terms of blocks, where one block comprises 64 bytes. When the DBLB bit is set to 1 by software, this controller assigns two planes of the FIFO buffer size specified by the BUFSIZE bits to the selected pipe. Specifically, the following expression determines the FIFO buffer size assigned to the selected pipe by this controller.
(BUFSIZE + 1) × 64 × (DBLB + 1) [bytes]

Set the following value in these bits.
(1) When pipes 1 to 5 are selected, any value from 0h to 1Fh can be set.
(2) When pipes 6 to 9 are selected, only 0h should be set.

When used with CNTMD = 1, set an integral multiple of the maximum packet size to the BUFSIZE bits.

32.2.13.4 Pipe Maximum Packet Size Register (PIPEMAXP)

Address(es): A006 006Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	MXPS[10:0]										
Value after hardware reset:	0	0	0	0	x	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b10 to b0	MXPS[10:0]	Maximum Packet Size	Specify the maximum data payload (maximum packet size) of the selected pipe. Pipes 6 to 9 can be set to 01h to 40h bytes.	R/W	R
b15 to b11	—	Reserved	When writing to these bits, write 0.	R/W	—

Note 1. The value after a reset of the MXPS bit is 00h when no pipe is selected with the PIPESEL bits in PIPESEL and 40h when a pipe is selected with the PIPESEL bits in PIPESEL.

Maximum Packet Size Bits (MXPS)

Set the maximum data payload (maximum packet size) for the selected pipe in these bits.
For pipes 1 and 2, a value between 1 byte (1h) to 1024 bytes (400h) can be set.
For pipes 3 to 5, any value from 8 bytes (8h), 16 bytes (10h), 32 bytes (20h), 64 bytes (40h) and 512 bytes (200h) can be set (bits [2:0] are not provided).
The value after a reset is 040h (64 bytes).

These bits should be set to the appropriate value for each transfer type based on the USB specification.
Set these bits to 1 while PID is NAK and before setting the CURPIPE bits.
Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

While MXPS is 0, do not write to the FIFO buffer or set PID to BUF.

32.2.13.5 Pipe Timing Control Register (PIPEPERI)

Address(es): A006 006Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b2 to b0	IITV[2:0]	Interval Error Detection Spacing	Specify the interval error detection timing for the selected pipe in terms of frames, which is expressed as n-th power of 2.	R/W	R
b11 to b3	—	Reserved	When writing to these bits, write 0.	R/W	—
b12	IFIS	Isochronous IN Buffer Flush	Specifies whether to flush the buffer when the pipe selected by the PIPESEL bits (selected pipe) is used for isochronous IN transfers. 0: The buffer is not flushed 1: The buffer is flushed	R/W	R
b15 to b13	—	Reserved	When writing to these bits, write 0.	R/W	—

Interval Error Detection Spacing Bits (IITV)

Specify the interval error detection timing in terms of frames, which is expressed as n-th power of 2, in these bits.

These bits should be modified while PID is NAK and before setting the CURPIPE bits.
Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Before modifying these bits after USB communication has been completed with these bits set to a certain value, set PID to NAK and then set ACLRM to 1 to initialize the interval timer.

The IITV bits are invalid for pipes 3 to 5; set these bits to 0 for these pipes.

These bits can be set when the selected pipe transfer is for isochronous transfers.

(1) When the selected pipe is for isochronous OUT transfers

This controller generates the NRDY interrupt when it fails to receive a data packet within the interval set for (μ) frames by the IITV bits.

This controller generates the NRDY interrupt when this controller fails to receive a data packet because of a CRC error or other errors contained in the packet, or because of the FIFO buffer being full (because reading data from the FIFO buffer by software (DMAC) is slow).

This controller generates the NRDY interrupt on receiving an SOF packet. Even if the SOF packet is corrupted, the internal interpolation is used and allows the interrupt to be generated at the timing to receive the SOF packet. However, when the IITV bits are set to the value other than 0, this controller generates the NRDY interrupt on receiving an SOF packet for every interval after starting interval counting operation.

When the PID bits are set to NAK by software after starting the interval timer, this controller does not generate the NRDY interrupt on receiving an SOF packet.

The interval counting starts at the different timing depending on the IITV bit setting as follows.

(a) When IITV = 0: The interval counting starts when the PID bits for the selected pipe are set to BUF.

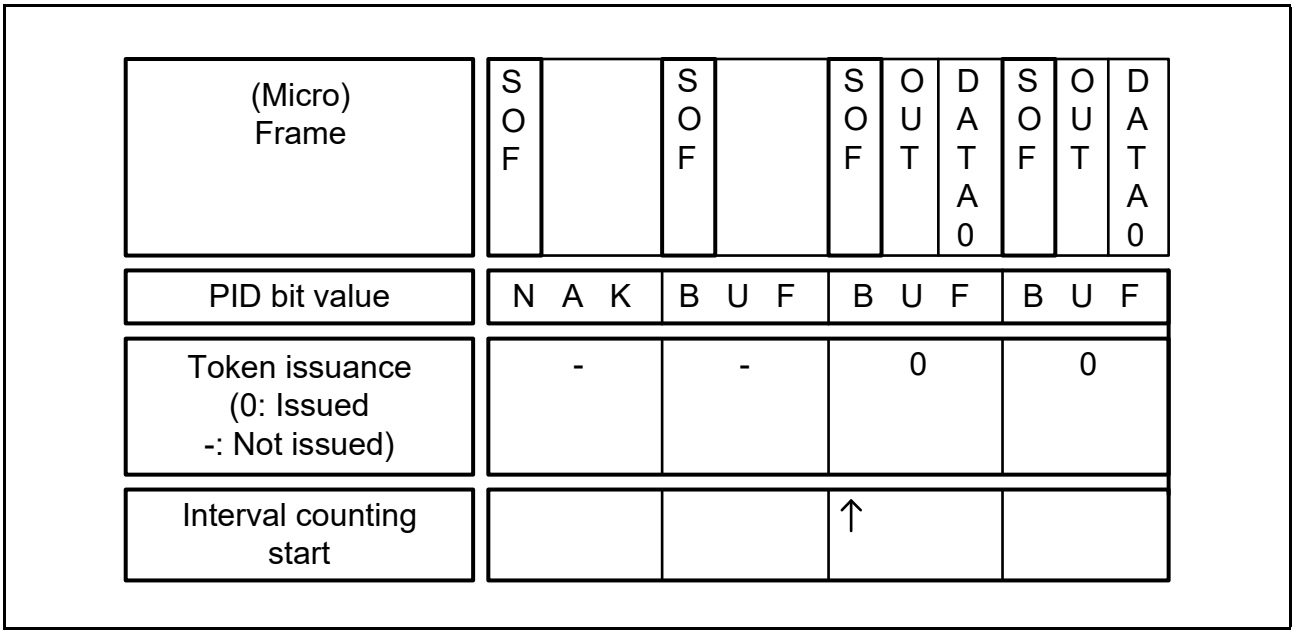

Figure 32.2 Relationship between (μ) Frames and Expected Token Reception when IITV = 0

(b) When IITV ≠ 0: The interval counting starts on completion of successful reception of the first data packet after the PID bits for the selected pipe have been modified to BUF.

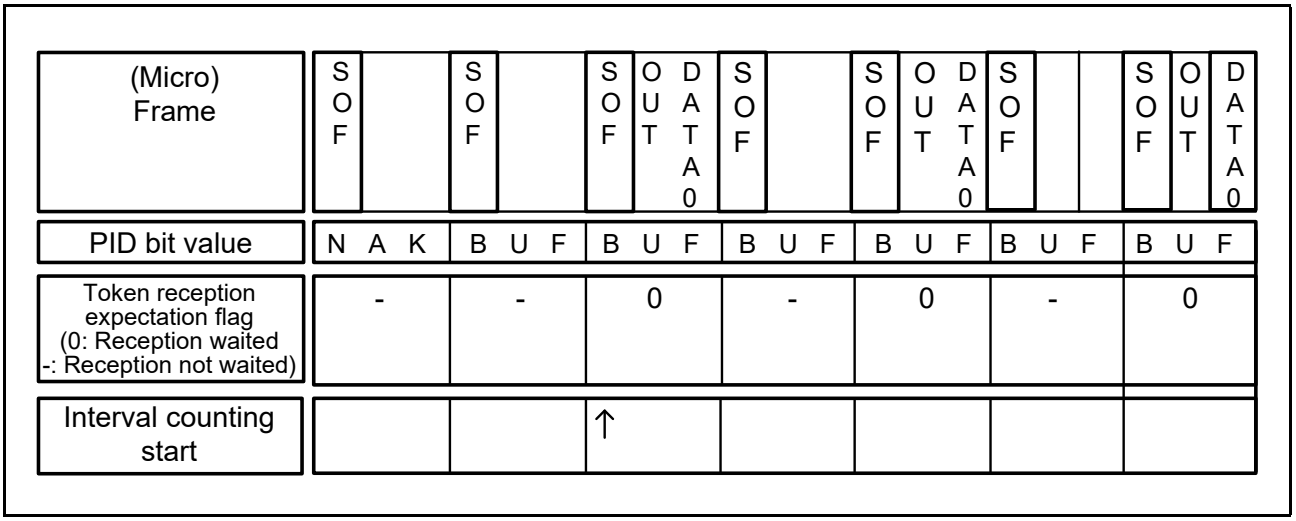

Figure 32.3 Relationship between (μ) Frames and Expected Token Reception when IITV = 1

(2) When the selected pipe is for isochronous IN transfers

The IFIS bit should be 1 for this use. When IFIS = 0, this controller transmits a data packet in response to the received IN token irrespective of the IITV bit setting.

When IFIS = 1, this controller clears the FIFO buffer when this controller fails to receive an IN token within the interval set for (μ) frames by the IITV bits in a state in which there is data to be transmitted in the FIFO buffer.
This controller also clears the FIFO buffer when this controller fails to receive an IN token successfully because of a bus error such as a CRC error contained in the token.
This controller clears the FIFO buffer on receiving an SOF packet. Even if the SOF packet is corrupted, the internal interpolation is used and allows the FIFO buffer to be cleared at the timing to receive the SOF packet.

The interval counting starts at the different timing depending on the IITV bit setting (similar to the timing during OUT transfers).

The counting conditions for the interval counter are any of the following.

(1) When a hardware reset is applied to this controller (at this point, the value of the IITV bits is also cleared to 0).
(2) When the ACLRM bit is set to 1 by software.
(3) When the controller detects a USB bus reset.

Isochronous IN Buffer Flush Bit (IFIS)

When the selected pipe is for isochronous IN transfers, this controller automatically clears the FIFO buffer when this controller fails to receive the IN token from the USB host within the interval set by the IITV bits in terms of (μ) frames. In double-buffer operation (DBLB = 1), this controller only clears the data in the plane used earlier.
This controller clears the FIFO buffer on receiving the SOF packet immediately after the (μ) frame in which this controller has expected to receive the IN token. Even if the SOF packet is corrupted, this controller also clears the FIFO buffer at the right timing to receive the SOF packet by using the internal interpolation.

When the selected pipe is not for the isochronous transfer, set this bit to 0.

b7	SQSET	Toggle Bit Set	Specifies 1 when setting the expected value of the sequence toggle bit in the next transaction of the selected pipe, to DATA1. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect. 1: Specifies DATA1	R/W	R
b8	SQCLR	Toggle Bit Clear	Specifies 1 when clearing the expected value of the sequence toggle bit in the next transaction of the selected pipe, to DATA0. This bit is read as 0. When writing to this bit, only 1 can be written. 0: Writing has no effect. 1: Specifies DATA0	R/W	R
b9	ACLRM	Auto Buffer Clear Mode	Enables or disables automatic buffer clear mode for the selected pipe. 0: Disabled 1: Enabled (all buffers are initialized)	R/W	R

Bit	Symbol	Bit Name	Description	S/W	H/W
b10	ATREPM	Auto Response Mode	Enables or disables auto response mode for the selected pipe. 0: Disabled 1: Enabled (a zero-length packet response while sending, NAK response and an NRDY interrupt is issued while receiving)	R/W	R
b12, b11	—	Reserved	When writing to these bits, write 0.	R/W	—
b13			When writing to this bit, write 1. However, this bit is read as 0.	R/W	—
b14	INBUFM	Transfer Buffer Monitor	Indicates the selected FIFO buffer state when the selected pipe is in the transmitting direction. 0: FIFO buffer contains no transmittable data. 1: FIFO buffer contains transmittable data.	R	W
b15	BSTS	Buffer Status	Indicates the FIFO buffer state of the selected pipe. 0: Buffer access is disabled. 1: Buffer access is enabled.	R	W

Response PID Bits (PID)

Set a response of the controller in each pipe in this bit by the software.

The default value of this bit is NAK. When executing a USB transfer through the selected pipe, change the setting of the PID bits to select BUF. The basic operations (operations when there is no error in the communication packet) of this controller for each value of the PID bit are given in Table 32.12.

To change the PID bits from BUF to NAK by a software while USB communications through the selected pipe is in progress, confirm that the USB transfer status of the known pipe has changed to NAK by reading PBUSY = 0. Note that reading of the PBUSY bit by a software is not required if the setting of the PID bits was changed to NAK by the controller.

In following cases, the controller modifies the value of this bit:

(1) When the selected pipe is for receiving and when the software has written 1 to the SHTNAK bit of the selected pipe, the controller sets PID = NAK upon identifying the transfer end.

(2) For the selected pipe, when the data packet of payload exceeding the maximum packet size is received, the controller sets PID = STALL (11b).

(3) When the USB bus reset is detected, the controller sets PID = NAK.

Write 10b to shift from PID = NAK (00b) to PID = STALL.
Write 11b to shift from BUF (01b) to STALL.
First write 10b and then write 00b to shift form STALL (11b) to NAK.
First, shift to NAK and then to BUF to shift from STALL to BUF.

Table 32.12 List of Controller Operations According to the PID Bit

PID Bit Value	Transfer Type (TYPE Bits Value)	Transfer Direction (DIR Bit Value)	Controller Operations
00b (NAK)	Bulk (TYPE = 01b) or Interrupt (TYPE = 10b)	Not dependent on setup value	NAK response is sent to the token from the USB host.
	Isochronous (TYPE = 11b)	Reception (DIR = 0)	Does not respond to the token from the USB host.
		Transmission (DIR = 1)	A zero-length packet is sent to the token from the USB host.
01b (BUF)	Bulk (TYPE = 01b)	Reception (DIR = 0)	When an OUT token is sent from the USB host, if the FIFO buffer for the selected pipe is ready for reception, the data is received and an ACK or NYET response is returned. A NAK response is returned if not ready. When a PING token is sent from the USB host, if the FIFO buffer of the selected pipe is ready for reception, an ACK response is returned. A NAK response is returned if not ready.
	Interrupt (TYPE = 10b)	Reception (DIR = 0)	For the Out token from the USB host, if the FIFO buffer of the selected pipe is ready for reception, the data is received and an ACK response is sent. A NAK response is returned if not ready.
	Bulk (TYPE = 01b) or Interrupt (TYPE = 10b)	Transmission (DIR = 1)	If the corresponding FIFO buffer is ready for transmission, the data is sent for the token from the USB. A NAK response is returned if not ready.
	Isochronous (TYPE = 11b)	Reception (DIR = 0)	For the Out token from the USB host, if the FIFO buffer of the selected pipe is ready for reception, the data is received. The data is deleted if not ready.
		Transmission (DIR = 1)	If the corresponding FIFO buffer is ready for transmission, the data is sent for the token from the USB. A zero-length packet is sent if not ready.
10b (STALL) or 11b (STALL)	Bulk (TYPE = 01b) or Interrupt (TYPE = 10)	Not dependent on setup value	A STALL response is sent to the token from the USB host.
	Isochronous (TYPE = 11b)	Not dependent on setup value	Returns nothing in response to the token from the USB host.

PIPE Busy Bit (PBUSY)

This controller modifies this bit from 0 to 1 upon start of the USB transaction for the selected pipe, and modifies the bit from 1 to 0 upon completion of one transaction.

Reading this bit after PID has been set to NAK allows checking that modification of the pipe settings is possible.

Sequence Toggle Bit Monitor Bit (SQMON)

This bit indicates the expected value of the sequence toggle bit of the selected pipe.

When the selected pipe is not for the isochronous transfer, this bit is toggled upon normal completion of the transaction. However, this bit is not toggled when a DATA-PID disagreement occurs during the receiving transfer.

Sequence Toggle Bit Set Bit (SQSET)

Setting this bit to 1 by software allows this controller to set DATA1 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Set this bit to 1 while PID is NAK.
Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Sequence Toggle Bit Clear Bit (SQCLR)

Setting this bit to 1 by software allows this controller to set DATA0 as the expected value of the sequence toggle bit of the selected pipe. This bit always indicates 0.

Set this bit to 1 while PID is NAK.
Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Auto Buffer Clear Mode Bit (ACLRM)

To clear the contents in the FIFO buffer assigned to the selected pipe completely, write 1 and then 0 to this bit continuously.
Table 32.13 shows the contents cleared by writing 1 and 0 to this bit continuously.
Table 32.14 shows the cases in which clearing the contents is necessary.

Table 32.13 Contents Cleared by this Controller by Setting ACLRM = 1

No.	Contents Cleared by ACLRM Bit Manipulation
(1)	All the contents in the FIFO buffer assigned to the selected pipe (all the information in two FIFO buffer planes in double-buffer operation)
(2)	The interval count value when the selected pipe is for isochronous transfer

Table 32.14 Cases where Setting ACLRM = 1 is Required

No.	Case where Clearing is Required
(1)	All the contents in the FIFO buffer assigned to the selected pipe are to be cleared.
(2)	The interval counter is to be reset.
(3)	When the BFRE setting is modified
(4)	When the DBLB setting is modified
(5)	When the transaction count function is forcibly terminated

Set this bit to 1 while PID is NAK and before specifying the pipe in CURPIPE bits. Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Auto Response Mode Bit (ATREPM)

When the selected pipe is for bulk transfer, this bit can be set to 1.
When this bit is set to 1, this controller responds to the token from the USB host as described below.

(1) When the selected pipe is for bulk IN transfer (when TYPE = 01b and DIR = 1)
When ATREPM = 1 and PID = BUF, this controller transmits a zero-length packet in response to the IN token. This controller updates (toggles) the sequence toggle bit (DATAPID) each time this controller receives the ACK from the USB host (in a single transaction, IN token is received, zero-length packet is transmitted, and then ACK is received). In this case, this controller does not generate the BRDY or BEMP interrupt.

(2) When the selected pipe is for bulk OUT transfer (when TYPE = 01b and DIR = 0)
When ATREPM = 1 and PID = BUF, this controller returns NAK in response to the OUT token (or PING token) and generates the NRDY interrupt.

This bit should be modified while PID is NAK. Before setting this bit to 1 after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

For USB communication in auto response mode, set this bit to 1 while the FIFO buffer is empty. Do not write to the FIFO buffer during USB communication in auto response mode.

When the selected pipe is for isochronous transfer, be sure to set this bit to 0.

Transmission Buffer Monitor Bit (INBUFM)

When the selected pipe is in the transmitting direction (DIR = 1), this controller sets this bit to 1 when writing to at least one FIFO buffer plane is completed by software (or DMAC).
This controller sets this bit to 0 when this controller completes transmitting the data from the FIFO buffer plane to which all data has been written. In double-buffer operation (DBLB = 1), this controller sets this bit to 0 after this controller has completed transmitting the data from both FIFO buffer planes but before it has completed writing data to a single FIFO buffer plane.

This bit indicates the same value as the BSTS bit when the selected pipe is in the receiving direction (DIR = 0).

Buffer Status Bit (BSTS)

This bit indicates whether access from the CPU to the FIFO buffer assigned to the selected pipe is enabled or disabled.
The meaning of the BSTS bit depends on the setting of the DIR, BFRE and DCLRM bits as follows.

Table 32.15 BSTS Bit Operations

DIR Bit Value	BFRE Bit Value	DCLRM Bit Value	Meaning of BSTS Bit
0	0	0	1: The received data can be read from the FIFO buffer. 0: The received data has been completely read from the FIFO buffer.
		1	Setting prohibited
	1	0	1: The received data can be read from the FIFO buffer. 0: The BCLR bit has been set to 1 after the received data has been completely read from the FIFO buffer.
		1	1: The received data can be read from the FIFO buffer. 0: The received data has been completely read from the FIFO buffer.
1	0	0	1: The transmit data can be written to the FIFO buffer. 0: The transmit data has been completely written to the FIFO buffer.
		1	Setting prohibited
	1	0	Setting prohibited
		1	Setting prohibited

b5	PBUSY	PIPE Busy	Indicates whether or not the selected pipe is being currently used for the USB bus. 0: The pipe is not being currently used for the USB bus. 1: The pipe is being currently used for the USB bus.	R	W
b6	SQMON	Toggle Bit Confirm	Sets the expected value of the sequence toggle bit in the next transaction of the selected pipe. 0: DATA0 1: DATA1	R	W
b7	SQSET	Toggle Bit Set	Specifies 1 while clearing the expected value of the sequence toggle bit in the next transaction of the selected pipe to DATA1.This bit is read as 0. When writing to this bit, write 1. 0: Writing has no effect. 1: Specifies DATA1	R/W	R
b8	SQCLR	Toggle Bit Clear	Specifies 1 while clearing the expected value of the sequence toggle bit in the next transaction of the selected pipe to DATA0. This bit is read as 0. When writing to this bit, write 1. 0: Writing has no effect. 1: Specifies DATA0	R/W	R
b9	ACLRM	Auto Buffer Clear Mode	Enables or disables automatic buffer clear mode for the selected pipe. 0: Disabled 1: Enabled (all buffers are initialized)	R/W	R
b12 to b10	—	Reserved	When writing to these bits, write 0.	R/W	—
b13			When writing to this bit, write 1. However, this bit is read as 0.	R/W	—
b14			When writing to this bit, write 0.	R/W	—
b15	BSTS	Buffer Status	Indicates the FIFO buffer state of the selected pipe. 0: Buffer access is disabled 1: Buffer access is enabled	R	W

As for the bits listed below, see the description of each bit in section 32.2.14.1, PIPE1 Control Register (PIPE1CTR) PIPE2 Control Register (PIPE2CTR) PIPE3 Control Register (PIPE3CTR) PIPE4 Control Register (PIPE4CTR) PIPE5 Control Register (PIPE5CTR).

- Response PID Bits (PID)
- PIPE Busy Bit (PBUSY)
- Buffer Status Bit (BSTS)
- Sequence Toggle Bit Monitor Bit (SQMON)
- Sequence Toggle Bit Set Bit (SQSET)
- Sequence Toggle Bit Clear Bit (SQCLR)

Auto Buffer Clear Mode Bit (ACLRM)

To clear all contents from the FIFO buffer allocated to the selected pipe, write 1 and 0 sequentially in the ACLRM bit. Table 32.16 shows the contents of data to be cleared by the controller when 1 and 0 are written to this bit sequentially. The cases that require this processing are listed in Table 32.17.

Table 32.16 Contents Cleared by the Controller when ACLRM = 1

No.	Contents Cleared by ACLRM Bit Manipulation
(1)	Entire contents of the FIFO buffer allocated to the selected pipe

Table 32.17 Cases where Setting ACLRM = 1 is Required

No.	Cases where Clearing is Required
(1)	All the contents in the FIFO buffer assigned to the selected pipe are to be cleared.
(2)	The interval counter is to be reset.
(3)	The value of the BFRE bit is changed.
(4)	The transaction count function is forcibly terminated.

The ACLRM bit should be set while PID = NAK and before specifying the pipe in the CURPIPE bits.
Before modifying this bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY is 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

32.2.15 Transaction Counters

32.2.15.1 PIPE1 Transaction Counter Enable Register (PIPE1TRE)
PIPE2 Transaction Counter Enable Register (PIPE2TRE)
PIPE3 Transaction Counter Enable Register (PIPE3TRE)
PIPE4 Transaction Counter Enable Register (PIPE4TRE)
PIPE5 Transaction Counter Enable Register (PIPE5TRE)

Address(es): PIPE1TRE: A006 0090h
PIPE2TRE: A006 0094h
PIPE3TRE: A006 0098h
PIPE4TRE: A006 009Ch
PIPE5TRE: A006 00A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	TRENB	TRCLR	—	—	—	—	—	—	—	—
Value after hardware reset:	x	x	x	x	x	x	0	0	x	x	x	x	x	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b7 to b0	—	Reserved	When writing to these bits, write 0.	R/W	—
b8	TRCLR	Transaction Counter Clear	The transaction counter can be cleared to 0 by writing 1 to this bit. This bit is read as 0. When writing to this bit, write 1. 0: Invalid 1: The current counter value is cleared	R/W	R
b9	TRENB	Transaction Counter Enable	Enable or disables the transaction counter 0: The transaction counter is disabled 1: The transaction counter is enabled	R/W	R
b15 to b10	—	Reserved	When writing to these bits, write 0.	R/W	—

Note 1. Modify each bit in this register while PID is NAK.
Before modifying each bit after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.

Transaction Counter Clear Bit (TRCLR)

When this bit is set to 1 by software, this controller clears the current counter value of the transaction counter corresponding to the selected pipe and then sets this bit to 0.

Transaction Counter Enable Bit (TRENB)

For the pipe in the receiving direction, setting this bit is set to 1 by software after setting the total number of the packets to be received in the TRNCNT bits allows the following control on having received the number of packets equal to the set value in the TRNCNT bits.

(1) In continuous transmission/reception mode (CNTMD = 1), this module switches the FIFO buffer to the CPU side even if the FIFO buffer is not full on completion of reception.
(2) While SHTNAK is 1, this module changes the setting of the PID bits to NAK for the corresponding pipe on having received the number of packets equal to the set value in the TRNCNT bits.
(3) While DENDE is 1 and PKTMD is 0, the DEND signal is asserted when the number of packets specified in the TRNCNT bits is received and the last data is to be read.
(4) While BFRE is 1, this module asserts the BRDY interrupt on having received the number of packets equal to the set value in the TRNCNT bits and then reading out the last received data.

For the pipe in the transmitting direction, set this bit to 0.
When the transaction counter is not used, set this bit to 0.
When the transaction counter is used, set the TRNCNT bits before setting this bit to 1. Set this bit to 1 before receiving the first packet to be counted by the transaction counter.

32.2.15.2 PIPE1 Transaction Counter Register (PIPE1TRN)
PIPE2 Transaction Counter Register (PIPE2TRN)
PIPE3 Transaction Counter Register (PIPE3TRN)
PIPE4 Transaction Counter Register (PIPE4TRN)
PIPE5 Transaction Counter Register (PIPE5TRN)

Address(es): PIPE1TRN: A006 0092h
PIPE2TRN: A006 0096h
PIPE3TRN: A006 009Ah
PIPE4TRN: A006 009Eh
PIPE5TRN: A006 00A2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TRNCNT[15:0]															
Value after hardware reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b15 to b0	TRNCNT [15:0]	Transaction Counter	When written to: Specify the total number of reception packets (number of transactions) to be received by the selected pipe. When read from: Indicate the specified number of transactions if TRENB is 0. Indicate the number of currently counted transaction if TRENB is 1.	R/W	R/W

Transaction Counter Bits (TRNCNT)

For the pipe in the receiving direction, setting these bits to 1 by software after setting the total number of the packets to be received in the TRNCNT bits allows the control of the transaction counter clear bit (TRCLR).
When TRENB = 0, these bits indicate the number of transactions set by software.
When TRENB = 1, these bits indicate the number of transactions being currently counted.

This controller increments the value of these bits by one when all of the following conditions are satisfied on receiving the packet.

(a) TRENB = 1
(b) (TRNCNT setting ≠ current counter value +1) on receiving the packet
(c) The payload of the received packet agrees with the set value in the MXPS bits.

This module clears the value of these bits to 0 when any of the following conditions are satisfied.

(1) When all the following conditions are satisfied:
(a) TRENB = 1
(b) (TRNCNT setting = current counter value +1) on receiving the packet
(c) The payload of the received packet agrees with the set value in the MXPS bits.

(2) When both of the following conditions are satisfied:
(a) TRENB = 1
(b) A short packet is received.

(3) When the following condition is satisfied:
(a) When the TRCLR bit is set to 1 by software

For the pipe in the transmitting direction, set these bits to 0. When the transaction counter is not used, set these bits to 0.

These bits should be modified while PID is NAK and TRENB is 0.
Before modifying these bits after changing the setting of the PID bits for the selected pipe from BUF to NAK, check that PBUSY = 0. However, checking of the PBUSY bit is not required if the setting of the PID bits has been changed to select NAK response by the controller.
To modify the value of these bits, set TRCLR to 1 before setting TRENB to 1.

32.2.16 Low-Power Status Register (LPSTS)

Address(es): A006 0102h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	SUSPM	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after hardware reset:	x	0	x	0	x	x	x	0	x	x	x	x	0	x	0	0
Value after USB bus reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	S/W	H/W
b13 to b0	—	Reserved	When writing to these bits, write 0.	R/W	—
b14	SUSPM	UTMI SuspendM Control	Controls the SuspendM signal to the UTMI. 0: UTMI suspend mode 1: UTMI normal mode	R/W	R/W
b15	—	Reserved	When writing to this bit, write 0.	R/W	—

UTMI SuspendM Control Bit (SUSPM)

The USBf module controls output of the clock signal from the PLL in the USB-PHY layer. Accordingly, supply of the clock signal to the USBf module is stopped while SUSPM = 0.
After setting this bit to 1, wait for at least 100 us to allow oscillation of the UTMI clock to become stable.

Writing to this controller is disabled when the SUSPM bit is set to 0 (the UTMI clock is stopped). Reading from the controller area is allowed. However, writing to the registers listed in Table 32.18 is enabled even when the SUSPM bit is set to 0.

Table 32.18 List of Registers that can be Written by Software when SUSPM = 0

Address	Register Name
A006 0000h	SYSCFG0
A006 0002h	SYSCFG1
A006 0102h	LPSTS

However, the value written to the SYSCFG0 register while the UTMI clock is stopped (SUSPM = 0) is reflected after the UTMI clock oscillation is started (SUSPM = 1).

32.2.17 FIFO Continuous Transfer Ports

32.2.17.1 D0FIFO Continuous Transfer Port Register n (D0FIFOBn) (n = 0 to 7)
D1FIFO Continuous Transfer Port Register n (D1FIFOBn) (n = 0 to 7)

b15 to b5	—	Reserved	When writing to these bits, write 0.	R/W	—

Note: Placing the PLL in the PHY layer in power-down mode is prohibited once the PHY-PLL has been activated.

P1PORTSEL[1:0]

Port connection path selection input signals
00b: Signals are not driven.
01b: USB host controller
10b: Setting prohibited
11b: USB function controller

PHYPD

USB PHY power-down signal
0: Normal mode
1: Power-down mode

PHYRESET

USB PHY reset input
0: Release from the reset state
1: The reset signal is asserted.

PHYVBUSIN

This bit sets the VBUS input to the USB PHY layer. The setting of this bit enables the pull-up resistor for the D+ signal.
0: No VBUS input (D+ pull-up resistor disabled)
1: VBUS input (D+ pull-up resistor enabled)

32.3 Operation

32.3.1 System Controls and Oscillation Controls

This section describes the register operations required for initial settings of this module, and the registers necessary for power consumption control. The startup sequence is as follows.

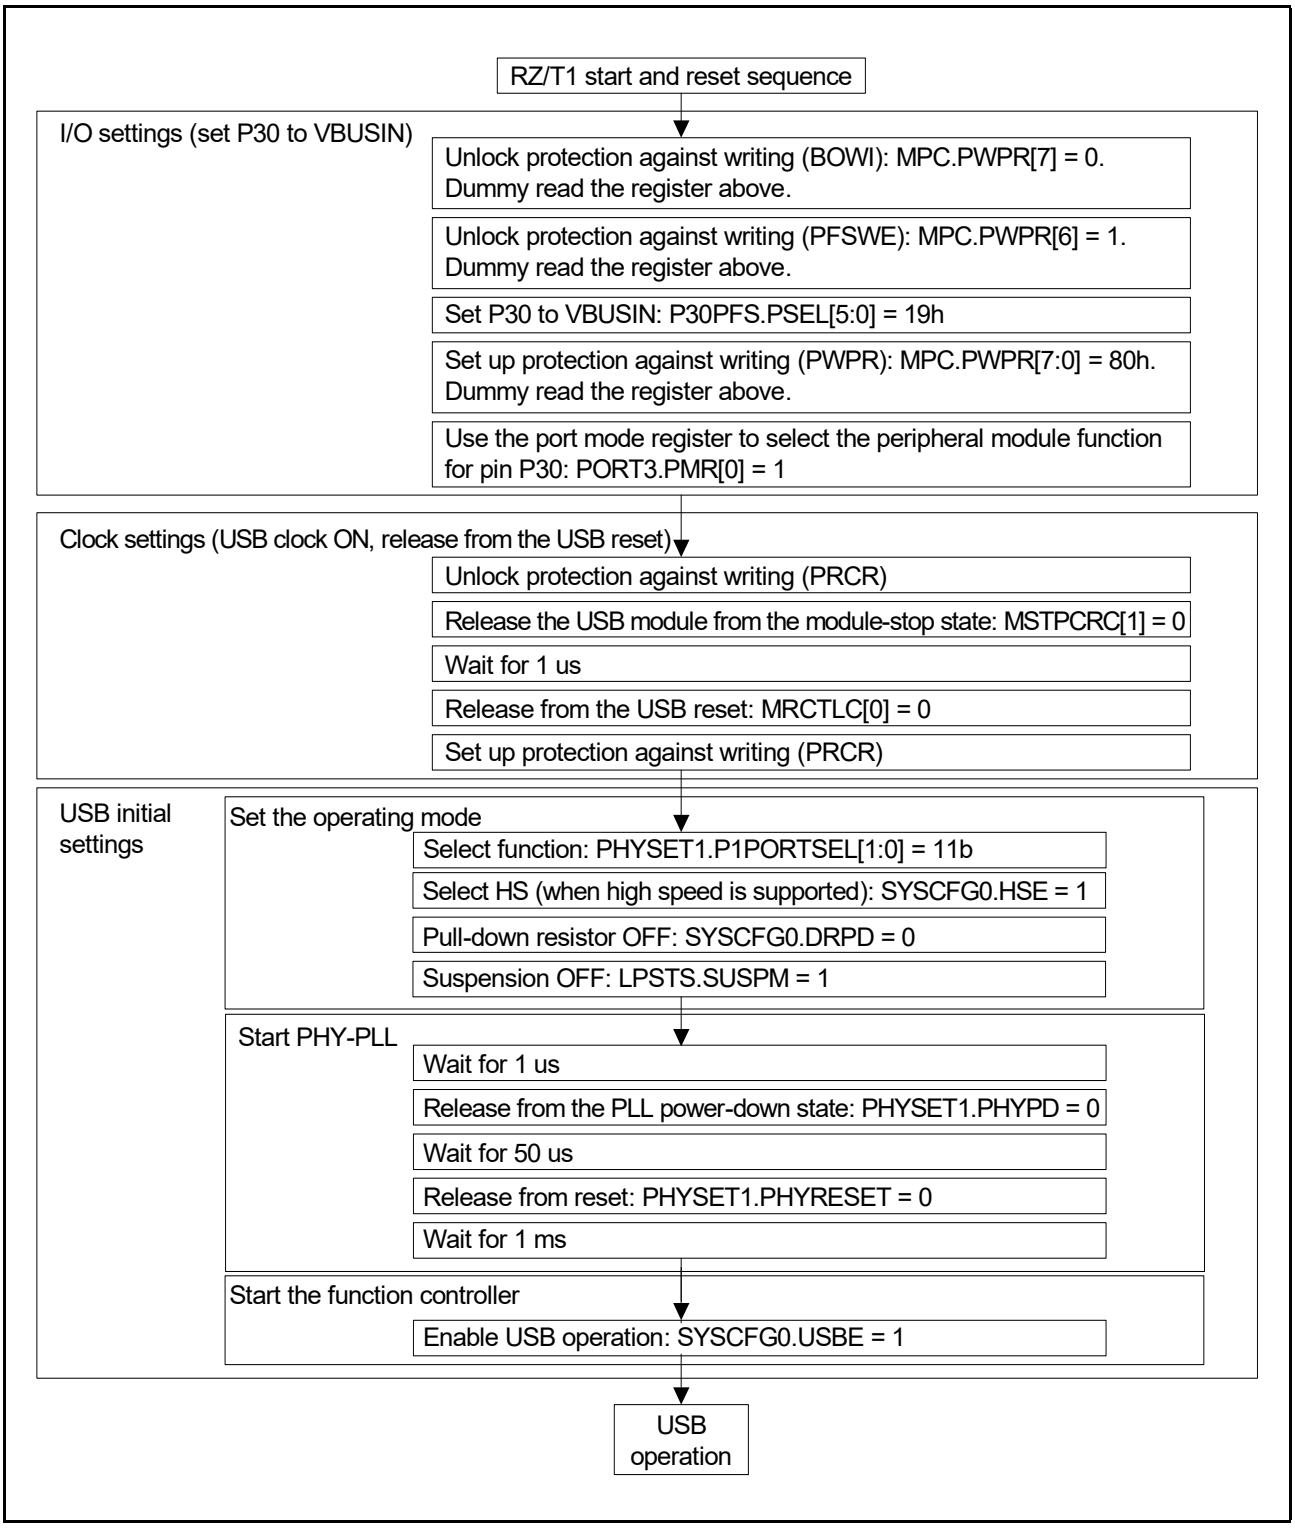

Figure 32.4 Startup Sequence

32.3.2 Resets

Table 32.19 lists the types of reset for this controller. For the initial states of the registers following the reset operations, refer to section 5, I/O Registers.

Table 32.19 Types of Reset

Name	Operation
USB bus reset	Automatically detected by this module from the D+ and D- lines

32.3.3 USB Data Bus Resistor Controller

This controller controls the pull-up resistors for the D+ signal of the USB2.0-PHY port.
Make pull-up setting for the D+ signal using the DPRPU and DRPD bits of the SYSCFG0 register.

Confirm the connection to the USB Host before setting the DPRPU bit of the SYSCFG0 register to 1 to pull up D+.
Set PHYSET1.PHYVBUSIN to 1 at the same time.

This controller incorporates termination resistors for the D+ and D- signals (in high-speed operation mode) and output resistors (in full-speed operation mode). The switching of the internal resistors following the connection to the PC is automatically done by the controller during reset handshake, suspend, and resume processing.

If the DPRPU bit of the SYSCFG0 register is set to 0 during communication with the PC, the controller disables the pull-up resistors (or termination resistors) of the USB data lines, so that it can notify the host controller of the disconnection of the device. At that time, set PHYSET1.PHYVBUSIN to 0 at the same time.

32.3.4 Supply of Clocks

Table 32.20 lists two clocks required for this controller.

Table 32.20 Input Clocks

Input Clock Name	Description
CPU clock (CPUCLK)	CPU clock input There are no restrictions on the clock frequency.
PHY clock (UTMI clock)	PHY clock input 60 MHz is internally supplied.

32.3.5 Notes on Stopping Clocks

- The PHY clock can be stopped with the SUSPM register in suspend mode.
- If a clock is to be stopped while the controller is in USB suspended state, however, it is necessary to resume the supply of the clock during resume processing. The resumption of the PHY clock need be accomplished within 5.5 ms after a resume interrupt occurs.
- After starting the PLL in the USB-PHY, do not stop it by setting the PHY power down bit (PHYSET1.PHYPD) or the PHY reset bit (PHYSET1.PHYRESET).
- When the USB function is not in use, place the USB module in the module-stop state (MSTPCRC[1] = 1 (MRCTLC[0] = 1 for making the USB reset setting)).

32.4 Interrupt Functions

32.4.1 Overview of Interrupt Functions

Table 32.21 lists the interrupt functions of this controller.

Table 32.21 List of Interrupt Functions

Bit	Interrupt Name	Interrupt Source	Related Status
VBINT	VBUS interrupt	When a change in the state of the VBUS input pin has been detected (low to high or high to low).	VBSTS
RESM	Resume interrupt	When a change in the state of the USB bus has been detected in the suspended state (J-state to K-state or J-state to SE0)	—
SOFR	Frame number update interrupt	If SOFRM = 0: When an SOF packet with a different frame number is received. If SOFRM = 1: When an SOF packet for a μ frame number of 0 cannot be received due to a corrupted packet.	—
DVST	Device state transition interrupt	When transition in device state is detected: A USB bus reset detected The suspended state detected Set Address request received Set Configuration request received	DVSQ
CTRT	Control transfer stage transition interrupt	When a stage transition is detected in control transfer: Setup stage completed Control write transfer status stage transition Control read transfer status stage transition Control transfer completed A control transfer sequence error occurred	CTSQ
BEMP	Buffer empty interrupt	When the buffer becomes empty after all data in the buffer memory has been transmitted. When a packet exceeding the maximum packet size is received.	PIPEBEMP
NRDY	Buffer not ready interrupt	When a token is received when PID = BUF and the buffer memory is not ready to transmit or receive data. When a CRC error or bit stuff error occurs while receiving data in isochronous transfer. When an interval error occurs while receiving data in isochronous transfer.	PIPENRDY
BRDY	Buffer ready interrupt	When the buffer is ready (readable or writable).	PIPEBRDY

Table 32.22 shows operations for a USBf interrupt output from this controller. In case more than one interrupt source is generated, the USBf interrupt output method can be set by using the INTL bit in the SOFCFG register. Set the USBf interrupt output operation according to the user system.

Table 32.22 Operations for USBf Interrupt Output

USBf Interrupt output pin operation / INTL Setting	When One Interrupt Source is Generated	When More than One interrupt Source is Generated
Edge sense (INTL = 0)	Holds the pin low until the interrupt source is cleared.	Negated (H pulse output) for 32 clock cycles at 48 MHz when one source is cleared.
Level sense (INTL = 1)	Holds the pin low until the interrupt source is cleared.	Holds the pin low until all sources are cleared.

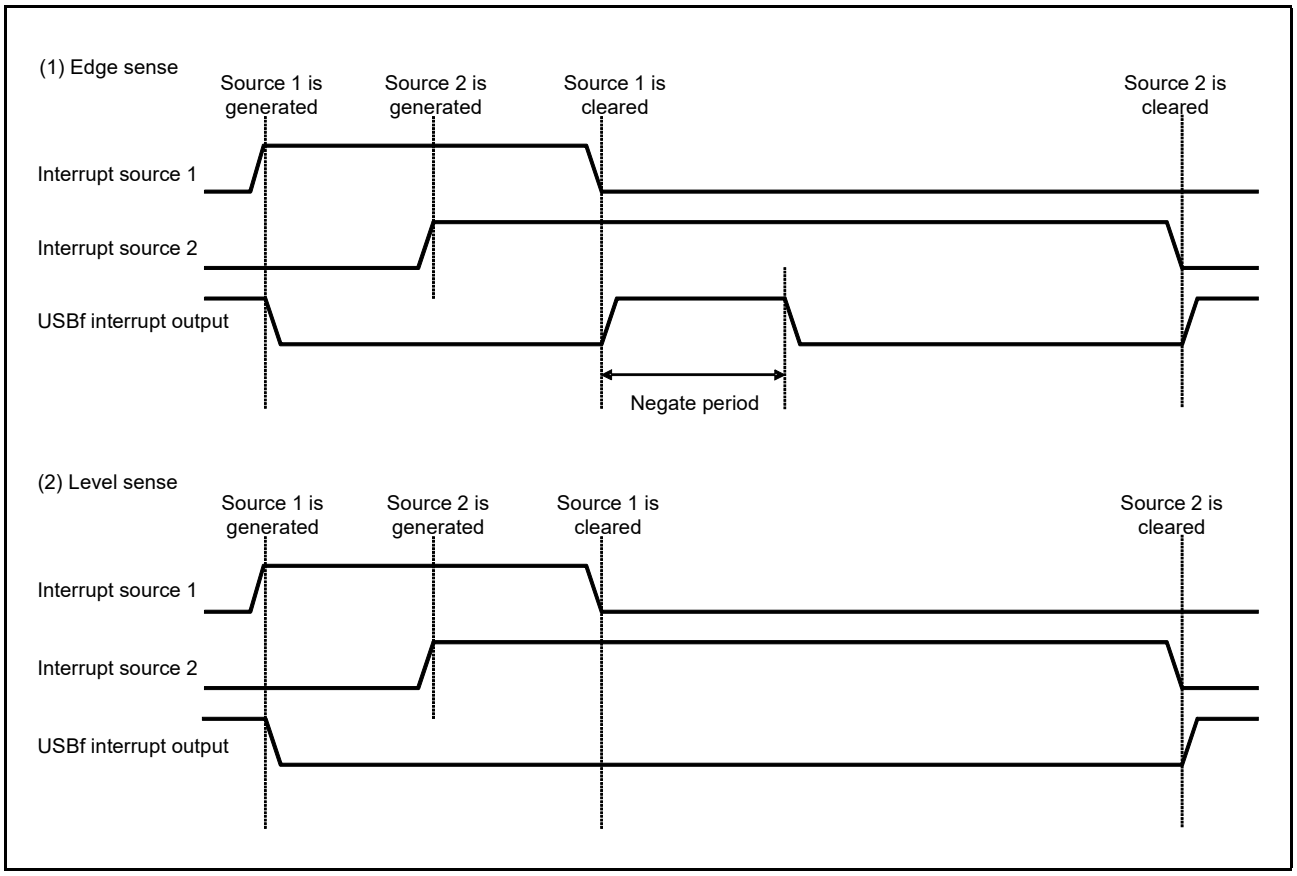

Figure 32.5 USBf Interrupt Output Operation Diagram

Figure 32.6 shows the interrupt configurations for the controller.

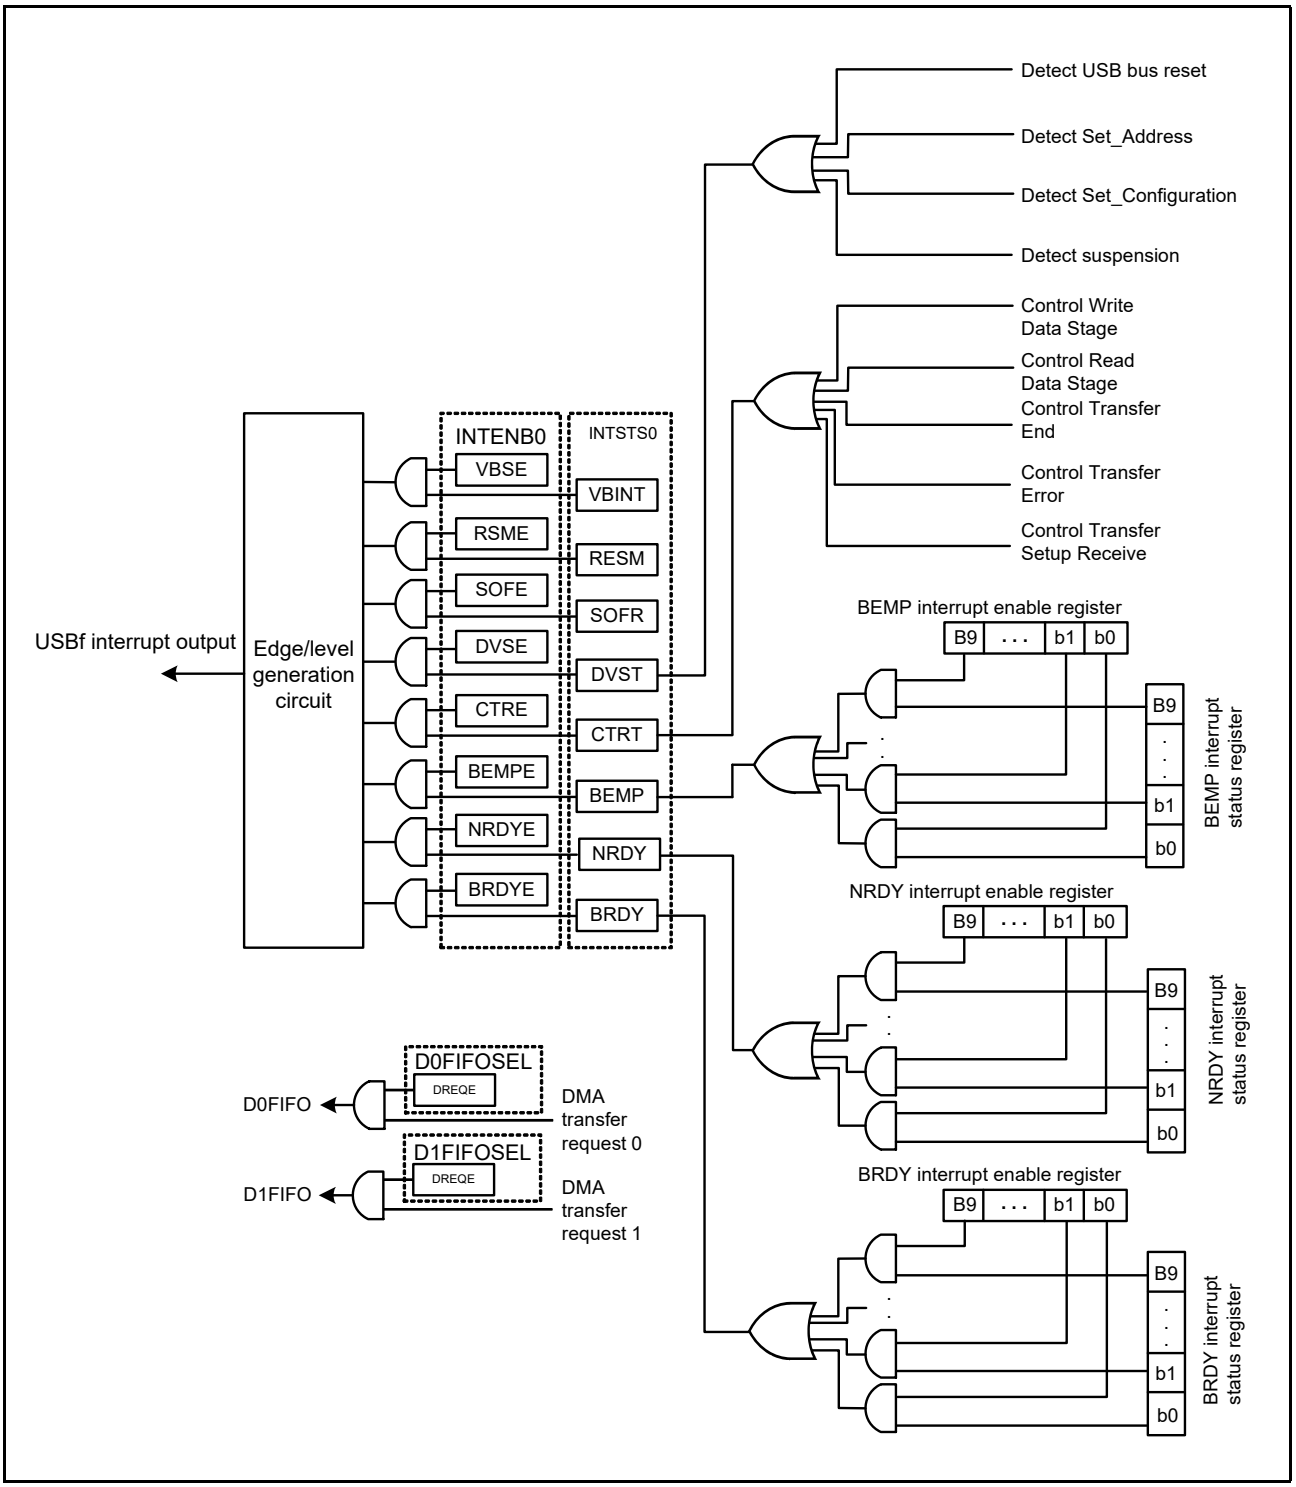

Figure 32.6 Interrupt Configuration Diagram

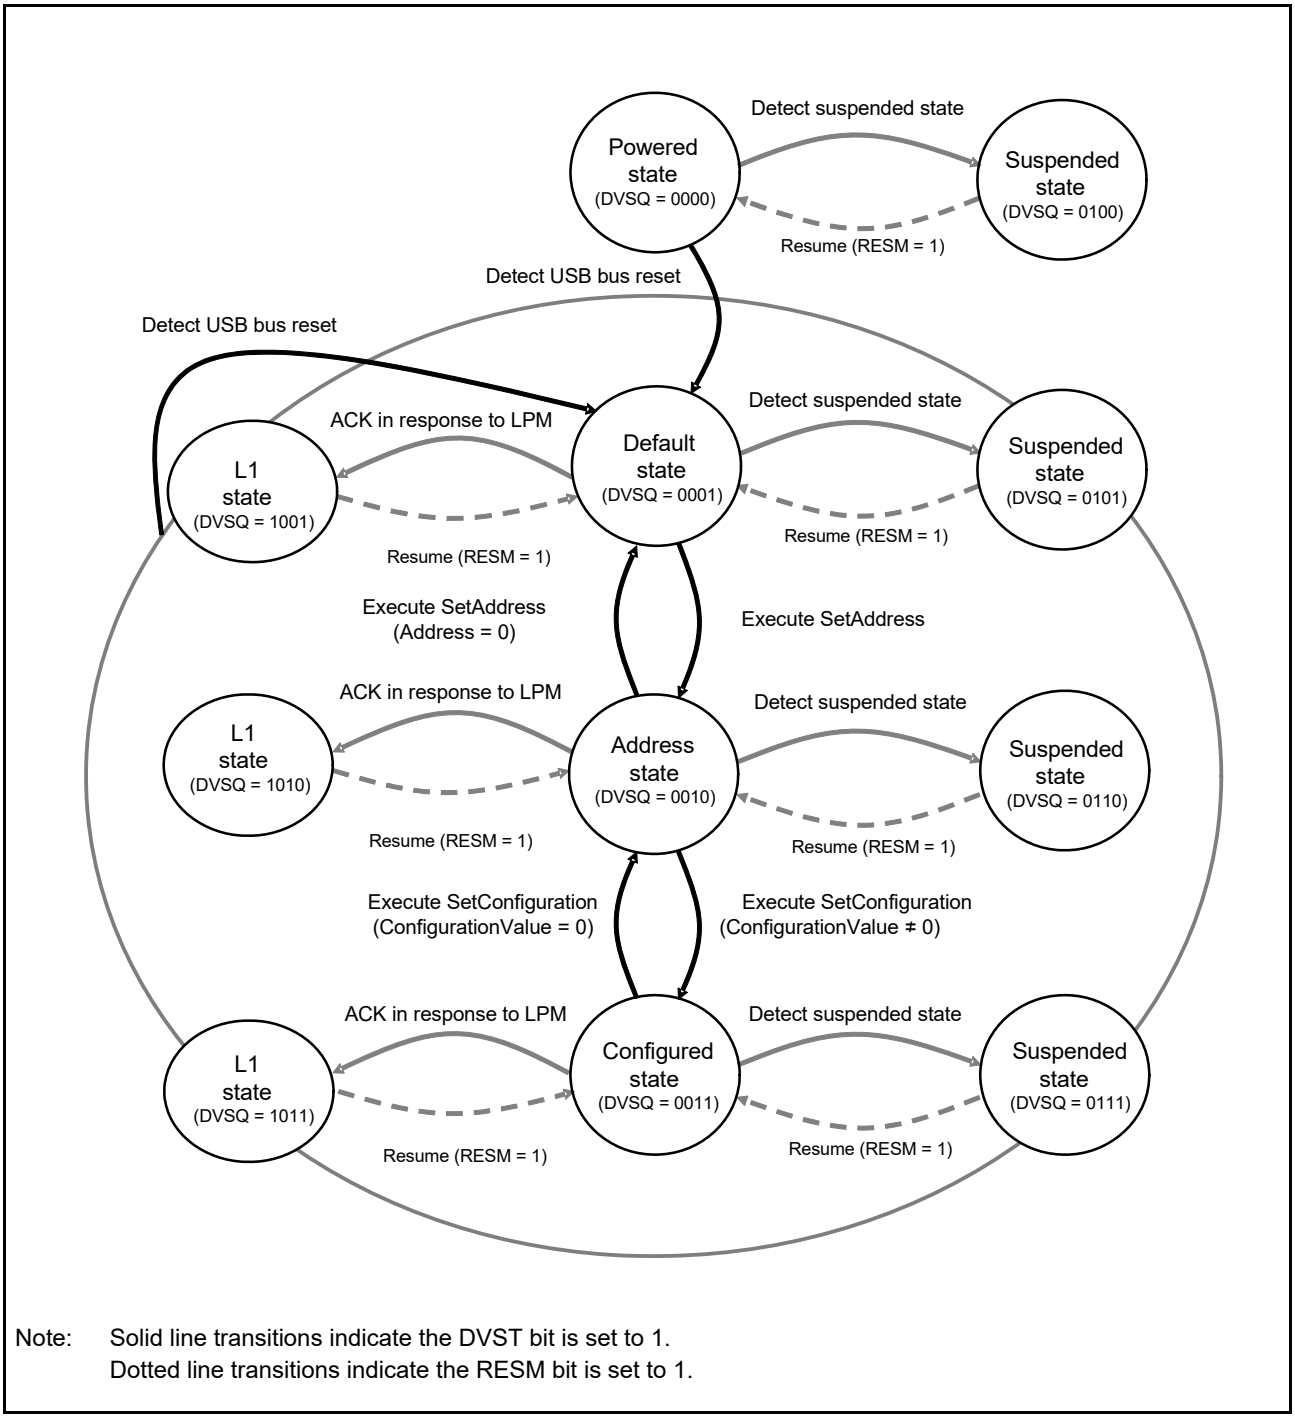
32.4.2 Device State Transition Interrupt

Figure 32.7 shows a diagram of how this module handles the device state transitions. The controller monitors the device states and generates the device state transition interrupts. However, recovery from the suspended state (resume signal detection) is detected by the resume interrupt. The device state transition interrupts can be enabled or disabled individually by setting the INTENB0 register. The device state after a transition can be confirmed using the DVSQ bits in the INTSTS0 register.

When making a transition to the default state, the device state transition interrupt is generated after the reset handshake protocol has been completed.



Note: Solid line transitions indicate the DVST bit is set to 1.
Dotted line transitions indicate the RESM bit is set to 1.

Figure 32.7 Device State Transitions

32.4.3 Control Transfer Stage Transition Interrupt

Figure 32.8 shows a diagram of how this module handles the control transfer stage transition. The controller monitors the control transfer sequence and generates the control transfer stage transition interrupts. The control transfer stage transition interrupts can be enabled or disabled individually in the INTENB0 register. The control transfer stage after a transition can be confirmed in the CTSQ bits in the INTSTS0 register.

The control transfer sequence errors are described below. If an error occurs, the PID bits in DCPCTR are set to 1xb (STALL).

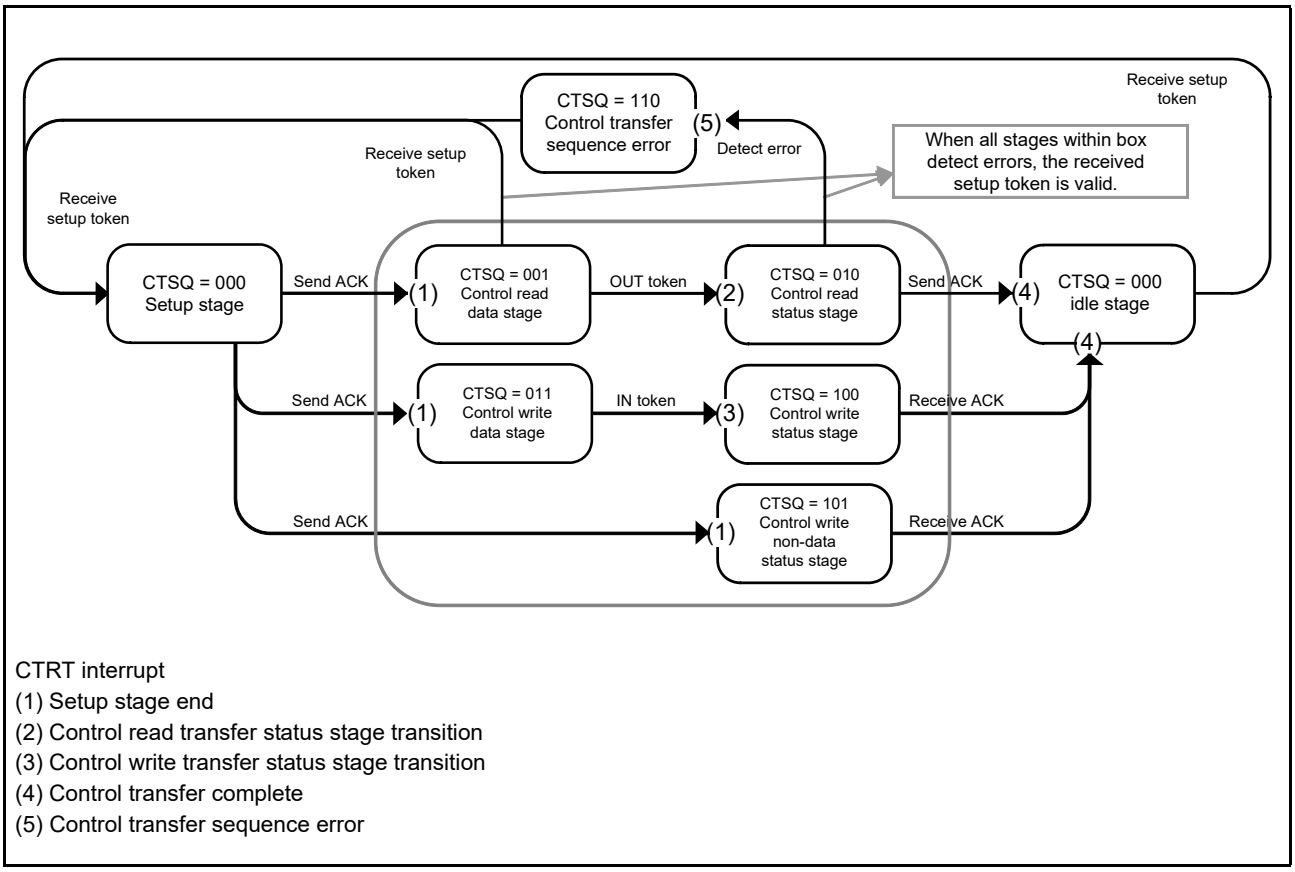
(1) During control read transfers
  (a) At the IN token of the data stage, an OUT or PING token is received when there have been no data transfers at all.
  (b) An IN token is received at the status stage.
  (c) A packet is received at the status stage for which the data packet is DATAPID = DATA0.

(2) During control write transfers
  (a) At the OUT token of the data stage, an IN token is received when there have been no ACK response at all.
  (b) A packet is received at the data stage for which the first data packet is DATAPID = DATA0.
  (c) At the status stage, an OUT or PING token is received.

(3) During control write no-data transfers
  (a) At the status stage, an OUT or PING token is received.

Note that in the control write transfer data stage, if the number of received data is more than the USB request wLength value, the control transfer sequence error cannot be recognized. Also, in the control read transfer status stage, when a packet other than a zero-length packet is received, an ACK response is returned and the transfer is successfully completed.

When a CTRT interrupt is generated due to a sequence error (SERR = 1), the value of CTSQ = 110b is retained until CTRT = 0 is written by the user system (clearing the interrupt state). Therefore, while CTSQ = 110 is retained, the CTRT interrupt for the completion of the setup stage is not generated, even when a new USB request is received. Events occurring after the setup stage are saved by the controller and the CTRT interrupt is generated after the interrupt state is cleared by software.



CTRT interrupt
(1) Setup stage end
(2) Control read transfer status stage transition
(3) Control write transfer status stage transition
(4) Control transfer complete
(5) Control transfer sequence error

Figure 32.8 Control Transfer Stage Transition

32.5 Pipe Control

Table 32.23 provides a list of pipe settings for the controller. In USB data transfers, data transmission is executed in logic pipes called endpoints. This controller comes with ten pipes for data transfer. Each pipe can be set to meet the requirements of the user system.

Table 32.23 Pipe Settings

Register Name	Bit Name	Setting	Remark
PIPECFG	TYPE	Specifies the transfer type	Can be set for pipes 1 to 9.
	BFRE	Selects BRDY interrupt mode	Can be set for pipes 1 to 5.
	DBLB	Selects double buffer configuration	Can be set for pipes 1 to 5.
	CNTMD	Selects continuous transfer or non-continuous transfer	Can be set for pipes 1 and 2 only in bulk transfers. Can be set for pipes 3 to 5.
	DIR	Selects transfer direction	Set to IN or OUT
	EPNUM	Endpoint number	Can be set for pipes 1 to 9. Set to a value other than 0000 when a pipe is in use.
	SHTNAK	Disables pipe when transfer is completed.	Can be set for pipes 1 and 2 only in bulk transfers. Can be set for pipes 3 to 5.
PIPEBUF	BUFSIZE	Buffer memory size	Cannot be set for DCP (fixed to 256 bytes). Up to 2 Kbytes can be set for pipes 1 to 5. Cannot be set for pipes 6 to 9 (fixed to 64 bytes).
	BUFNMB	Buffer memory number	Cannot be set for DCP (fixed at areas 0 to 3hex). Can be set for pipes 1 to 5 (specifiable in area ranging from 8 to 80hex). Cannot be set for pipes 6 to 9 (fixed at areas ranging from 4 to 7hex).
DCPMAXP PIPEMAXP	MXPS	Maximum packet size	Setting conforming to the USB standard
PIPEPERI	IFIS	Buffer flush	Can be set for pipes 1 and 2 only in isochronous transfers. Cannot be set for pipes 3 to 5. Cannot be set for pipes 6 to 9.
	IITV	Interval counter	Can be set for pipes 1 and 2 only in isochronous transfers. Cannot be set for pipes 3 to 5. Cannot be set for pipes 6 to 9.
DCPCTR PIPExCTR	BSTS	Buffer status	DCP state switched between receive and transmission buffer by ISEL bit
	INBUFM	IN buffer monitor	Available only for pipes 3 to 5.
	ATREPM	Auto response mode	Can be set for pipes 1 to 5.
	ACLRM	Auto buffer clear	Can be set for pipes 1 to 9.
	SQCLR	Sequence clear	Clears data toggle bit.
	SQSET	Sequence set	Sets data toggle bit.
	SQMON	Sequence check	Monitors data toggle bit.
	PBUSY	Pipe busy check	
	PID	Response PID	
PIPExTRE	TRENB	Transaction count enable	Can be set for pipes 1 to 5.
	TRCLR	Current transaction counter clear	Can be set for pipes 1 to 5.
PIPExTRN	TRNCNT	Transaction counter	Can be set for pipes 1 to 5.

32.5.1 Maximum Packet Size Setting

The MXPS bits in DCPMAXP and PIPEMAXP are used to specify the maximum packet size for each pipe. DCP and PIPE1 to PIPE5 can be set to any of the maximum packet sizes defined by the USB Specification. For PIPE6 to PIPE9, 64 bytes are the upper limit of the maximum packet size. The maximum packet size should be set before beginning the transfer (PID = BUF).
DCP: 64 should be set when using high-speed operation.
DCP: Select and set 8, 16, 32, or 64 when using full-speed operation.
Pipes 1 to 5: 512 should be set when using high-speed bulk transfer.
Pipes 1 to 5: Select and set 8, 16, 32, or 64 when using full-speed bulk transfer.
Pipes 1 to 2: Set a value between 1 and 1024 when using high-speed isochronous transfer.
Pipes 1 to 2: Set a value between 1 and 1023 when using full-speed isochronous transfer.
Pipes 6 to 9: Set a value between 1 and 64.

The high bandwidth transfers used with interrupt transfers and isochronous transfers are not supported.

32.5.2 Response PID

Set the response PID for each pipe with the PID bits of the DCPCTR and PIPExCTR registers.

(1) Response PID setting
The response PID specifies the response to a transaction from the Host.
(a) NAK setting: Always sends a NAK response when a transaction is issued.
(b) BUF setting: Responds to the transaction in accordance with the buffer memory state.
(c) STALL setting: Always sends a STALL response when a transaction is issued.
Regardless of the value set in the PID bit, an ACK is always sent as a response to a setup transaction and the USB request is stored in corresponding registers.

Based on the results of the transaction, the controller may trigger the PID bits to be written.
The controller will trigger a write event to the PID bit in the following cases.

- Hardware setting of response PID

(a) NAK setting:
1) When SETUP token is received normally (only DCP)
2) In bulk transfers when the SHTNAK bit of the PIPECFG register is set to 1 and short packet is received
3) In bulk transfers when SHTNAK bit is set to 1 and the transaction counter is completed.
(b) BUF setting: The BUF cannot be written by the controller.
(c) STALL setting:
1) When a maximum packet size over error is detected in the received data packet
2) When a control transfer sequence error is detected

32.5.3 Pipe Control Register Switching Procedures

The bits in the following pipe control registers can be re-written only when USB transmission is disabled (PID = NAK). Figure 32.9 shows the procedure for switching the pipe control register from the USB transmission enabled (PID = BUF) state.

Registers for which settings are prohibited when the USB transmission is enabled (PID = BUF):

- All bits of the DCPMAXP register
- Bits SQCLR and SQSET of the DCPCTR register
- All bits of the PIPECFG, PIPEBUF, PIPEMAXP and PIPEPERI registers
- ATREPM, ACLRM, SQCLR, and SQSET bits of the PIPExCTR register
- All bits of the PIPExTRE and PIPExTRN registers

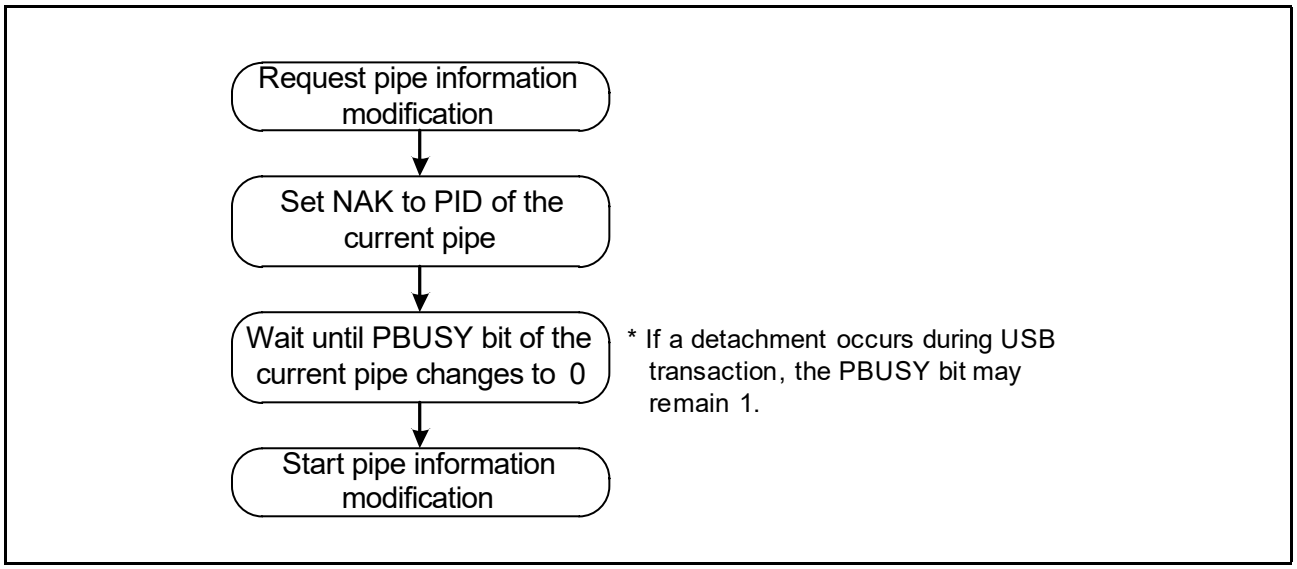


Figure 32.9 Procedure for Changing Pipe Information from USB Transmission Enabled (PID = BUF) State

In addition, the following bits of the pipe control registers can only be re-written with pipe information that is not set in the CURPIPE bits of CPU/DMA0/DMA1-FIFO ports.

Register for which settings are prohibited during setting of the CURPIPE bits in the FIFO port register:

- All bits of the DCPMAXP register
- All bits of the PIPECFG, PIPEBUF, PIPEMAXP and PIPEPERI registers
- Bit ACLRM of the PIPExCTR register

When modifying information of a pipe, specify other pipe number in the CURPIPE bits. Also, after setting the DCP pipe information, clear the buffer using the BCLR bit.

32.5.4 Data PID Sequence Bit

When a normal data transfer occurs in the control transfer data stage, bulk transfer or interrupt transfer, the controller automatically toggles the data PID sequence bit. The next data PID sequence bit for data transfer can be confirmed in the SQMON bit in the DCPCTR or PIPExCTR registers. The sequence bit is switched in the ACK handshake receive timing when data is sent or in the ACK handshake send timing when data is received. The data PID sequence bit can also be modified for the SQCLR and SQSET bits of the DCPCTR and PIPExCTR registers.
In control transfers, the controller automatically sets the sequence bit for stage transitions. DATA1 is established at the end of the setup stage. In the status stage, the controller does not reference the sequence bit and returns a response with PID = DATA1. Therefore, the bit does not need to be set with software. Note that the data PID sequence bit must be set with software when a ClearFeature request is received.
Finally, the sequence bit cannot be manipulated through the SQSET bit for the isochronous transfer setup pipe.

32.6 FIFO Buffers

This section describes the operation of the FIFO buffers in this controller.

32.6.1 FIFO Buffer Allocation

Figure 32.10 shows an example of memory map for the FIFO buffers of this controller. The FIFO buffer area is shared by the CPU controlling the user system and this controller. The access right of the FIFO buffers may be given to the user system (CPU side) or to this controller (SIE side).

An independent FIFO buffer area is allocated for each pipe. The memory area is made up of memory blocks of 64 bytes and defined by the starting block number (1 block is 64 bytes long) and the number of blocks (specified by the BUFNMB and BUFSIZE bits of the PIPEBUF register). If the CNTMD bit of the PIPExCFG register is set to continuous transfer mode, the value specified in the BUFSIZE bits must be an integral multiple of the maximum packet size. If the double buffer configuration is selected through the DBLB bit of the PIPExCFG register, two planes of memory area the size of which is specified by the BUFSIZE bits of the PIPEBUF register are allocated to a single pipe.

Two FIFO ports are used to access an FIFO buffer (data read/write). The pipe to be assigned to an FIFO port is designated by specifying the pipe number in the CURPIPE bits of the CFIFOSEL or DxFIFOSEL register.

The FIFO buffer state of each pipe can be confirmed by using the BSTS and INBUFM bits of the DCPCTR and PIPExCTR registers. The access right of a FIFO port can be confirmed by using the FRDY bit of the CFIFOCTR or DxFIFOCTR register.

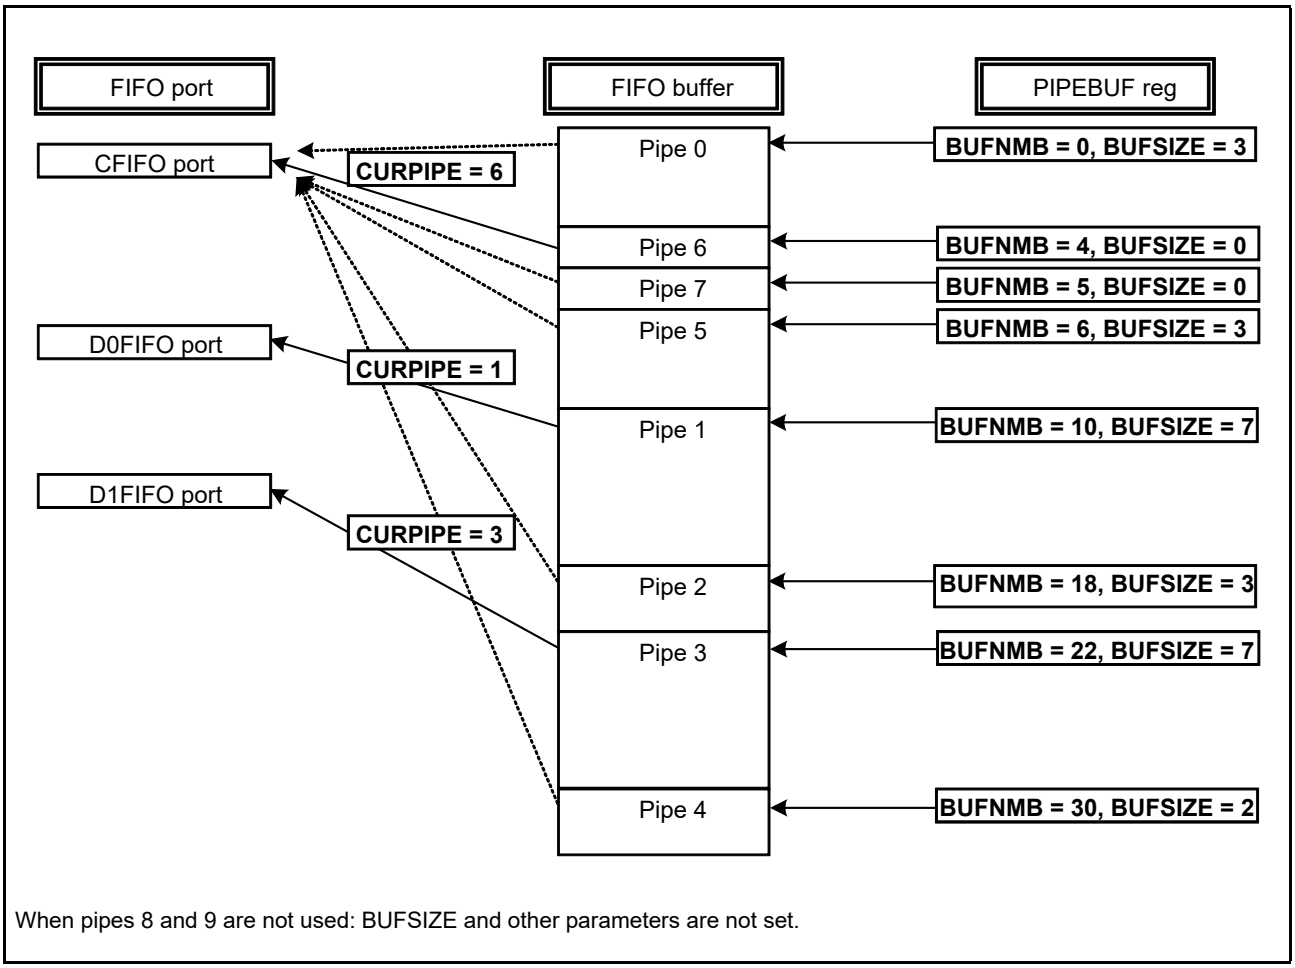

Figure 32.10 Example of FIFO Buffer Memory Map

32.6.2 Clearing FIFO Buffers

Table 32.24 shows a list of modes of clearing the FIFO buffers by this controller. The FIFO buffers can be cleared by the 3 bits that are listed in the table.

Table 32.24 List of FIFO Buffer Clearing Modes

Bit Name	BCLR	DCLRM	ACLRM
Register	CFIFOCTR register DxFIFOCTR register	DxFIFOSEL register	PIPExCTR register
Function	The FIFO buffer on the CPU side is cleared.	The FIFO buffer is automatically cleared after the data is read from the designated pipe.	The buffer is automatically cleared to discard all the received packets.
Clearing method	Write 1 to clear.	1: Mode valid 0: Mode invalid	1: Mode valid 0: Mode invalid

32.7 FIFO Port Function

This section describes FIFO port functions. Table 32.25 lists settings of FIFO port functions of this controller. If writing data is continued until the buffer becomes full (up to the maximum packet size in discontinuous transfer mode) during the data write access, the FIFO port automatically enters the state where data can be transmitted to the USB bus. To make data with a size less than the buffer full (the maximum packet size in discontinuous transfer mode) transmittable, write completion must be set by the BVAL bit in the CFIFOCTR or DxFIFOCTR register (DMA transfer: TEND signal of the DMAC (for details, see section 15, DMA Controller (DMACAa)). Furthermore, to transmit a zero-length packet, clear the buffer by the BCLR bit in the CFIFOCTR or DxFIFOCTR register and set write completion by the BVAL bit.
When all data has been read during the read access, the FIFO port automatically enters the state where a new packet can be received. However, when a zero-length packet is received (DTLN = 0), the data cannot be read. In that case, clear the buffer by the BCLR bit in the CFIFOCTR or DxFIFOCTR register. The receive data length is checked by the DTLN bits in the CFIFOCTR or DxFIFOCTR register.

Table 32.25 FIFO Port Function Settings

Register Name	Bit Name	Function	Notes
C/DxFIFOSEL	RCNT	DTLN read mode selection	
	REW	Buffer memory rewind (re-read, re-write)	
	DCLRM	Automatic clearing of buffer memory after specified pipe received data is read	DxFIFO only
	DREQE	DREQ signal assertion	DxFIFO only
	MBW	FIFO port access bit width	
	BIGEND	FIFO port endian selection	
	ISEL	FIFO port access direction	DCP only
	CURPIPE	Current pipe selection	
C/DxFIFOCTR	BVAL	Buffer memory write completion	
	BCLR	Clearing of CPU-side buffer memory	
	FRDY	Monitoring of FIFO port ready	
	DTLN	Confirmation of received data length	

32.7.1 FIFO Port Selection

Table 32.26 shows the list of pipes that can be selected in each FIFO port. The pipes to be accessed are selected with the CURPIPE bits of the CFIFOSEL or DxFIFOSEL register. After selecting the pipes, confirm that the value of the CURPIPE bits written was read correctly (if the previous pipe number is read out, this indicates the controller is still changing the pipe), then confirm that FRDY = 1 and access the FIFO port. Figure 32.11 shows the procedure for switching pipes for access to the FIFO port.
Also, select the bus width for the FIFO port access with the MBW bit. The buffer memory access direction is determined by the ISEL bit for DCP, and the DIR bit of the PIPExCFG register for all other pipes.

Table 32.26 FIFO Port Access by Pipe

Pipe	Access Method	Usable Ports
DCP	CPU access	CFIFO port register
Pipes 1 to 9	CPU access	CFIFO port register
	DMA access	DxFIFO port register

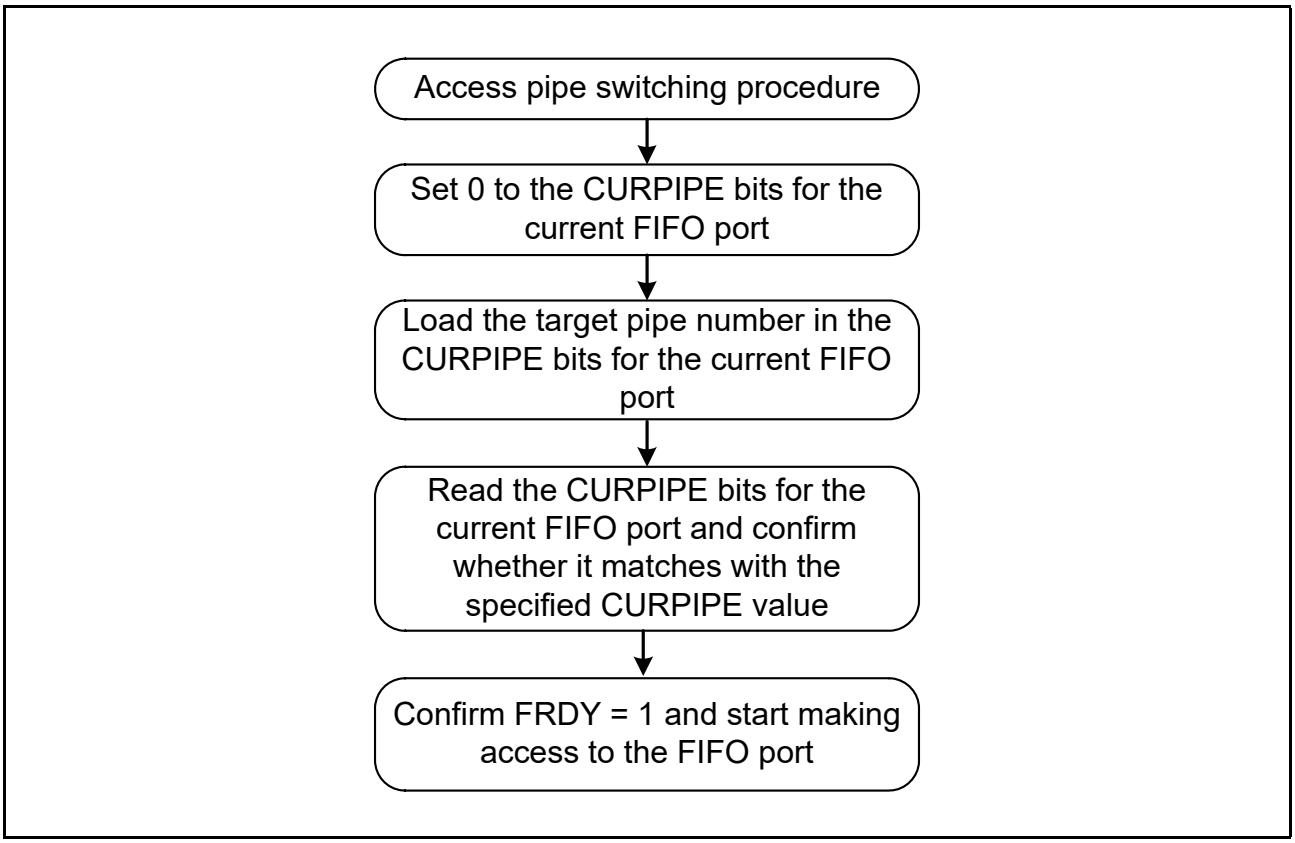

Figure 32.11 Pipe Switching Procedure for FIFO Port Access

32.7.2 DxFIFO Automatic Clear Mode (DxFIFO Port Read Direction)

When a data read event of the controller buffer memory is completed with setting the DCLRM bit of the DxFIFOSEL register to 1, the buffer memory of the corresponding pipe is automatically cleared.

Table 32.27 shows the correspondence between packet reception and buffer memory clearing by software in each setting.

As indicated in Table 32.27, the buffer clear conditions differ according to the set value of the BFRE bit, even for states in which clear is normally required, using the DCLRM bit eliminates the need for clearing of the buffer by software, enabling DMA transfers without the use of software.

Note that this function only supports the buffer memory read direction setting.

Table 32.27 Correspondence of Packet Reception and Buffer Memory Clearing by Software

Register Setting / Buffer State when Packet is Received	DCLRM = 0		DCLRM = 1	
	BFRE = 0	BFRE = 1	BFRE = 0	BFRE = 1
Buffer full	Clearing not required	Clearing not required	Clearing not required	Clearing not required
Zero-length packet received	Clearing required	Clearing required	Clearing not required	Clearing not required
Normal short packet received	Clearing not required	Clearing required	Clearing not required	Clearing not required
Transaction count end	Clearing not required	Clearing required	Clearing not required	Clearing not required

32.7.3 BRDY Interrupt Timing Selection

The BFRE bit of the PIPECFG register can be set so that the BRDY interrupt is not generated when a data packet of maximum packet size is received.

When using a DMA transfer, this function enables an interrupt to be generated only when the last data is received. The last data indicates either a short packet reception or the transaction count end. By setting BFRE = 1, the BRDY interrupt will be generated after the received data is read. By reading the DTLN bit of the DnFIFOCTR register, the receive data length of last data packet received just before the BRDY interrupt was generated can be confirmed.

Table 32.28 shows the timing of the BRDY interrupt.

Table 32.28 BRDY Interrupt Generation Timing

Register Setting / Buffer State when Packet is Received	BFRE = 0	BFRE = 1
Buffer full (normal packet received)	When packet is received	No interrupt generated
Zero-length packet received	When packet is received	When packet is received
Normal short packet received	When packet is received	When read event of data received from buffer memory is completed
Transaction count end	When packet is received	When read event of data received from buffer memory is completed

The BFRE bit function is only valid in reading direction of the buffer memory. When in writing direction, fix the BFRE bit to 0.

32.8 Control Transfer (DCP)

Data transfers of the data stage of control transfers are done using the default control pipe (DCP). The DCP buffer memory is a 64-byte single buffer, and is a fixed area that is shared for both control reading and control writing. The buffer memory can be accessed only through the CFIFO port.

32.8.1 Setup Stage

The controller always responds with an ACK when it receives a normal setup packet. The controller operations in the setup stage are as follows.

(1) When a new setup packet is received, the controller sets the following bits.
  (a) Sets the VALID bit of the INTSTS0 register to 1.
  (b) Sets the PID bits of the DCPCTR register to NAK.
  (c) Sets the CCPL bit of the DCPCTR register to 0.
(2) When a data packet is received following the setup packet, the USB request parameters are stored in the following registers: USBREQ, USBVAL, USBINDX and USBLENG.

Always set VALID = 0 before the response process to a control transfer. While VALID = 1, PID = BUF will not be set and the data stage cannot be completed.
The function of the VALID bit allows the controller to temporarily stop a request in-process when it receives a new USB request during a control transfer, and respond to the newest request.

In addition, the controller automatically judges the direction bit (bmRequestType bit 8) and the request data length (wLength) of the received USB request and determines whether it is a control read transfer, control write transfer or control write no-data transfer, and then handles the stage transition. If the sequence is incorrect, a sequence error for the control transfer stage transition interrupt is generated and is notified to the software. For more information concerning the controller stage management, see Figure 32.8.

32.8.2 Data Stage

Use the DCP for data transfers in response to receiving a USB request. Before accessing the DCP buffer memory, set the access direction in the ISEL bit of the CFIFOSEL register.
The transaction is executed by setting the PID bits of the DCPCTR register to BUF.
Data transfer completion is detected by the BRDY and BEMP interrupts. Use the BRDY interrupt for control write transfers and the BEMP interrupt for control read transfers.
For control write transfers in high-speed operation, a NYET handshake is sent in accordance with the buffer memory state.

32.8.3 Status Stage

When the setting of the PID bits of the DCPCTR register is BUF, set the CCPL bit to 1 to complete the control transfer. After the above settings, the controller automatically executes the status stage in accordance with the data transfer direction fixed in the setup stage. The detailed process is as follows.

(1) Control read transfers:
  The controller receives a zero-length packet from the USB host and sends an ACK response.
(2) Control write transfers and no-data control transfers:
  The controller sends a zero-length packet and receives an ACK response from the USB host controller.

32.8.4 Control Transfer Automatic Response

The controller automatically sends a response to a normal SET_ADDRESS request. If one of the following errors occurs, a response must be sent by software.

(1) bmRequestType ≠ 00h
(2) wIndex ≠ 00h
(3) wLength ≠ 00h
(4) wValue > 7Fh
(5) DVSQ = 011b (configured)

All requests other than the SET_ADDRESS request must be responded to by software.

32.9 Bulk Transfer (Pipes 1 to 5)

The user can select the buffer memory usage method (single/double buffer, continuous/non-continuous transfer mode) for bulk transfer. The maximum size that can be set for the buffer memory is 2 Kbytes. The controller manages the buffer memory state and automatically responds to PING packets and NYET handshakes.

32.9.1 NYET Handshake Control

Table 32.29 shows the list of responses to a token received in a bulk or control transfer. When an OUT token is received in a bulk or control transfer and there is only enough open space for one packet in the buffer memory, the controller sends a NYET response. However, when a short packet is received, the controller sends an ACK response instead of a NYET response, even under these conditions.

Table 32.29 List of Responses to Received Tokens

PID Bits Setting	Buffer Memory State	Received Token	Response	Notes
NAK/STALL	—	SETUP	ACK	—
	—	IN/OUT/PING	NAK/STALL	—
BUF	—	SETUP	ACK	—
	RCV-BRDY*1	OUT/PING	ACK	When OUT token is received, data packet is received.
	RCV-BRDY*2	OUT	NYET	Data packet is received.
	RCV-BRDY*2	OUT (Short)	ACK	Data packet is received.
	RCV-BRDY*2	PING	ACK	
	RCV-NRDY*3	OUT / PING	NAK	
	TRN-BRDY*4	IN	DATA0 / 1	Data packet is transmitted.
	TRN-NRDY*5	IN	NAK	

Note 1. RCV-BRDY: Buffer memory has enough space for 2 packets or more when an OUT or PING token is received.
Note 2. RCV-BRDY: Buffer memory has only enough space for one packet when an OUT token is received.
Note 3. RCV-NRDY: Buffer memory has not enough space when a PING token is received.
Note 4. TRN-BRDY: Buffer memory has data for transmission when an IN token is received.
Note 5. TRN-NRDY: Buffer memory does not have data for transmission when an IN token is received.

32.10 Interrupt Transfer (Pipes 6 to 9)

This controller executes an interrupt transfer in accordance with the period managed by the host controller. The controller ignores (no response) PING packets in interrupt transfers. In addition, the controller does not send a NYET handshake, but responds with ACK, NAK, or STALL.
The controller does not support high-bandwidth interrupt transfers.

32.11 Isochronous Transfer (Pipes 1 and 2)

The controller provides the following functions for isochronous transfers.

(1) Isochronous transfer error information notification
(2) Interval counter (IITV bit setting)
(3) Isochronous IN transfer data setup control (IDLY function)
(4) Isochronous IN transfer buffer flush function (IFIS bit setting)
(5) SOF pulse output function

The controller does not support high-bandwidth isochronous transfers.

32.11.1 Isochronous Transfer Error Detection

The controller manages isochronous transfer errors by software and therefore has the following error information detection functions. Table 32.30 and Table 32.31 describe the procedure in which errors are confirmed and the interrupts that are generated.

(1) PID error
When PID of the received packet is corrupted
(2) CRC error and bit stuffing error
When an error occurs in CRC of the received packet or when the bit stuffing is corrupted
(3) Maximum packet size over
This indicates the data size of the received packet is larger than the value set for the maximum packet size.
(4) Overrun and underrun
When there is no data in the buffer memory when an IN token is received in an IN-direction (send) transfer
When there is no empty space in the buffer memory when an OUT token is received in an OUT-direction (receive) transfer
(5) Interval error
The following will generate interval errors.
(a) When an IN token could not be received in the interval frame of an isochronous IN transfer
(b) When an OUT token could not be received in the interval frame of an isochronous OUT transfer

Table 32.30 Errors Detected in Token Reception/Transmission

Detection Priority	Error Type	Generated Interrupts and States at Time of Error Detection
1	PID error	No interrupt generated (ignored as corrupted packet)
2	CRC error or bit stuffing error	No interrupt generated (ignored as corrupted packet)
3	Overrun or underrun errors	NRDY interrupt is generated and OVRN bit is set. A zero-length packet is sent in response to an IN token. A data packet is not received in response to an OUT token.
4	Interval error	NRDY interrupt generated

Table 32.31 Errors Detected in Data Packet Reception

Detection Priority	Error Type	Generated Interrupts and States
1	PID error	No interrupt generated (ignored as corrupted packet)
2	CRC error or bit stuffing error	NRDY interrupt is generated and CRCE bit is set.
3	Maximum packet size over error	BEMP interrupt is generated and PID is set to STALL.

32.11.2 DATA-PID

This controller does not support high-bandwidth transfers. The following occurs in response to a received PID.

(1) IN direction:
  (a) DATA0: Transmitted as PID of the data packet
  (b) DATA1: Not transmitted
  (c) DATA2: Not transmitted
  (d) mDATA: Not transmitted

(2) OUT direction (in full-speed operation):
  (a) DATA0: Received successfully as PID of the data packet
  (b) DATA1: Received successfully as PID of the data packet
  (c) DATA2: The packet is ignored.
  (d) mDATA: The packet is ignored.

(3) OUT direction (in high-speed operation):
  (a) DATA0: Received successfully as PID of the data packet
  (b) DATA1: Received successfully as PID of the data packet
  (c) DATA2: Received successfully as PID of the data packet
  (d) mDATA: Received successfully as PID of the data packet

32.11.3 Interval Counter

32.11.3.1 Overview of Operation

The isochronous transfer interval can be set in the IITV bit of the PIPEPERI register. Table 32.32 shows the functions of the interval counter.

Table 32.32 Interval Counter Functions

Transfer Direction	Function	Detection Conditions
IN	Transfer buffer flush function	Cannot successfully receive IN token in interval frame during isochronous IN transfer.
OUT	Notifies that a token not being received	Cannot successfully receive OUT token in interval frame during isochronous OUT transfer.

Since the interval counting is performed upon reception of SOF or by the complemented SOF, the isochronism can be maintained even if the SOF is damaged. Frame intervals are set as 2^{IITV} (μ) frames.

32.11.3.2 Interval Counter Initialization

The controller initializes the interval counter under the following conditions.

(1) Hardware reset
Initializes the IITV bit.

(2) Clearing of the buffer memory by the ACLRM bit
This initializes the counter but not the IITV bit.

(3) USB bus reset

After the interval counter is initialized and a packet is successfully transferred, the interval count starts under the following conditions.

(1) SOF is received after data is sent in response to an IN token when PID = BUF.

(2) SOF is received after data is received in response to an OUT token when PID = BUF.

Note that the interval counter is not initialized in the following conditions.

(1) When the PID is set to NAK or STALL
The interval timer is not stopped at this time. The transaction will be attempted at the next interval.

(2) USB bus reset or USB suspend
The IITV bit is not initialized at this time. When the SOF is received, the count starts from the value before the reception.

32.11.4 Isochronous Transfer Transmission Data Setup

In the isochronous data transmission by this controller, after data is written to the buffer memory, the data packet can be sent out in the next frame after the SOF packet is detected. This function, called the isochronous transfer transmission data setup, allows specification of the frame that started transmission.
When the buffer memory is used for double buffering and writing to both buffers has been completed, only transfer from the first buffer to have received data can proceed. Therefore, even when several IN tokens are received in the same frame, only one packet of data is sent by the buffer memory.

When an IN token is received, if the buffer memory is ready for transmission, the data is transferred and a normal response is returned. However, if the buffer memory is not ready for transmission, a zero-length packet is sent and an underrun error occurs.

Figure 32.12 shows an example of transmission using the isochronous transfer transmission data setup function with this controller when IITV = 0 (for each frame) is set.

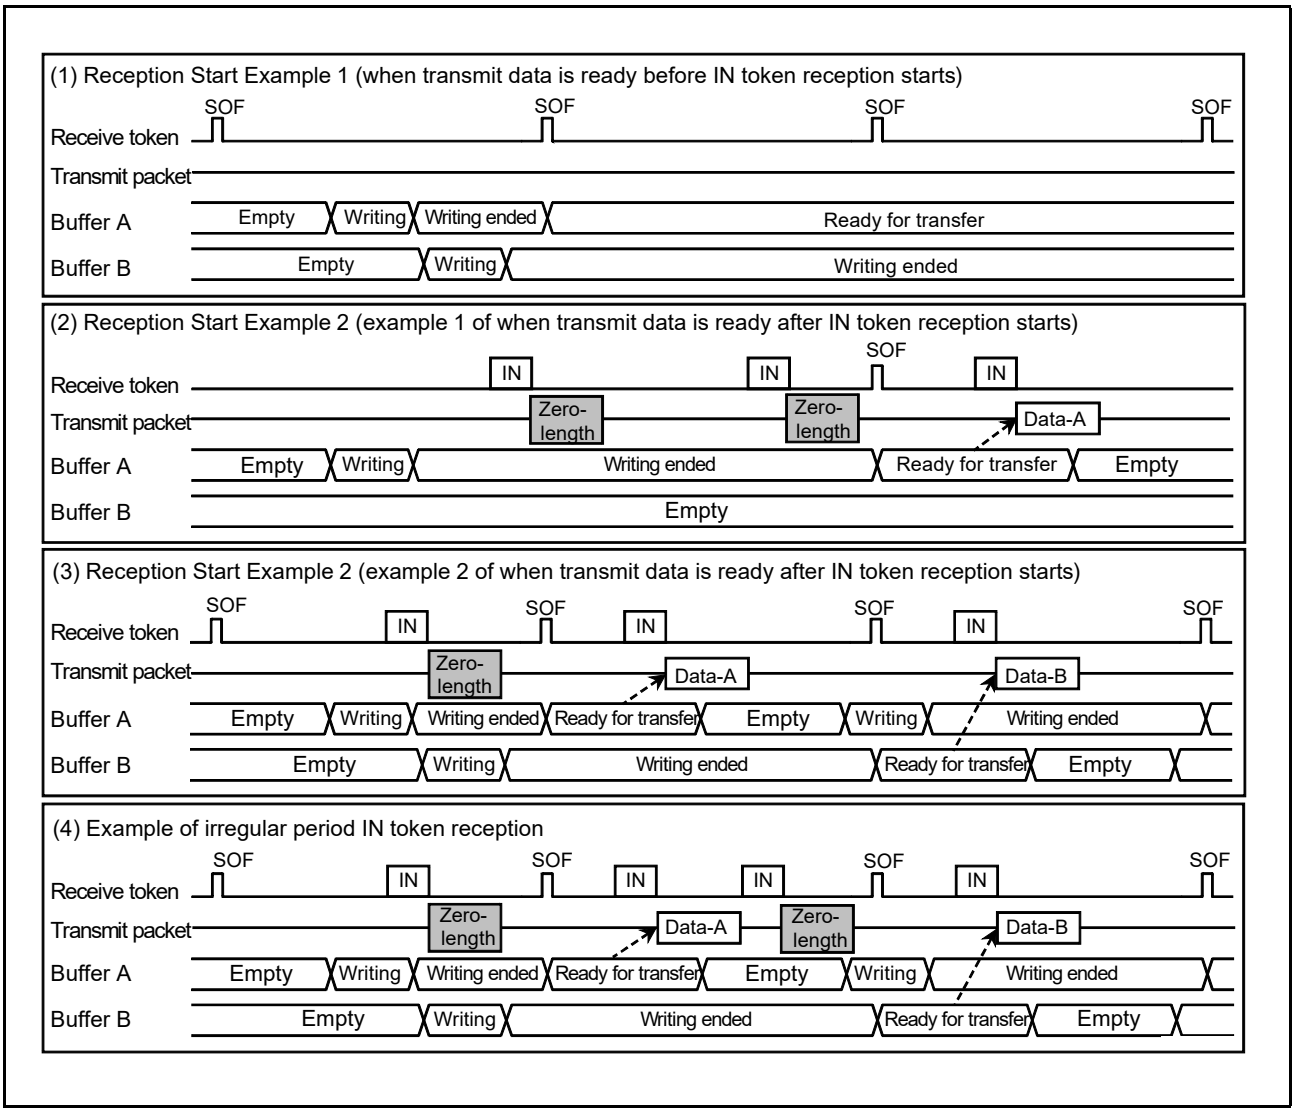

Figure 32.12 Example of Data Setup Function Operation

32.11.5 Isochronous Transfer Transmission Buffer Flush

When an SOF packet or a µSOF packet of the next frame is received without receiving an IN token in the interval frame during isochronous data transmission, this controller operates as if a corrupted IN token was received, and clears the buffer which is ready for transmission, making that buffer ready for writing.
If a double buffer is being used and writing to both buffers has been completed, data are considered to have been sent from the buffer memory that was cleared in the same interval frame, and transmission is enabled for the buffer memory that is not discarded with SOF or µSOF packets reception.
The timing at which the buffer flush function is activated varies depending on the setting of the IITV bits.

(1) When IITV = 0
The buffer flush operation proceeds from the first frame after the pipe becomes valid.

(2) When IITV ≠ 0
The buffer flush operation proceeds after the first successful transaction.

Figure 32.13 shows an operation example of the buffer flush function of this controller. When an unanticipated token is received prior to the interval frame, this controller sends the written data or a zero-length packet as an underrun error according to the data setup state.

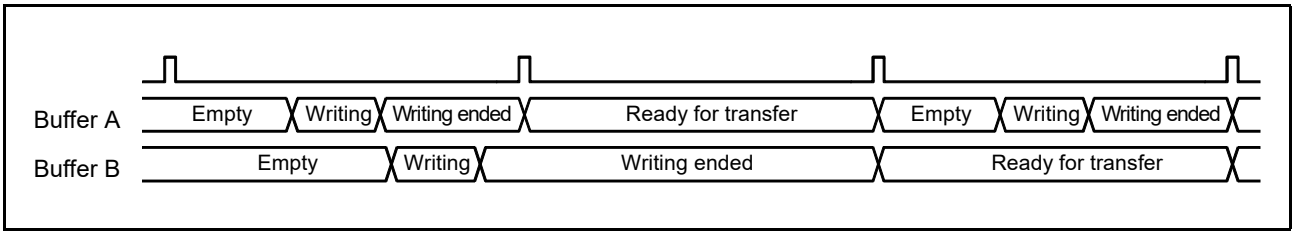

Figure 32.13 Buffer Flush Function Operation Example

Figure 32.14 shows an example of an interval error generated in the controller. There are five types of interval errors, as listed below. Timing 1 in the figure shows when the interval error occurs and how the buffer flush function operates.
When an interval error occurs during an IN transfer, the buffer flush function goes into operation; during an OUT transfer, the NRDY interrupt is generated.
Use the OVRN bit to determine whether an error is an NRDY interrupt, such as a receive packet error, or an overrun error.
Responses to the tokens in the shaded boxes are executed in accordance to the buffer memory state.

(1) IN direction:
  (a) If the buffer is ready for transfer, data is transferred as a normal response.
  (b) If the buffer is not ready for transfer, a zero-length packet is sent and an underrun error occurs.

(2) OUT direction:
  (a) If the buffer is ready for reception, data is received as a normal response.
  (b) If the buffer is not ready for reception, data is discarded and an overrun error occurs.

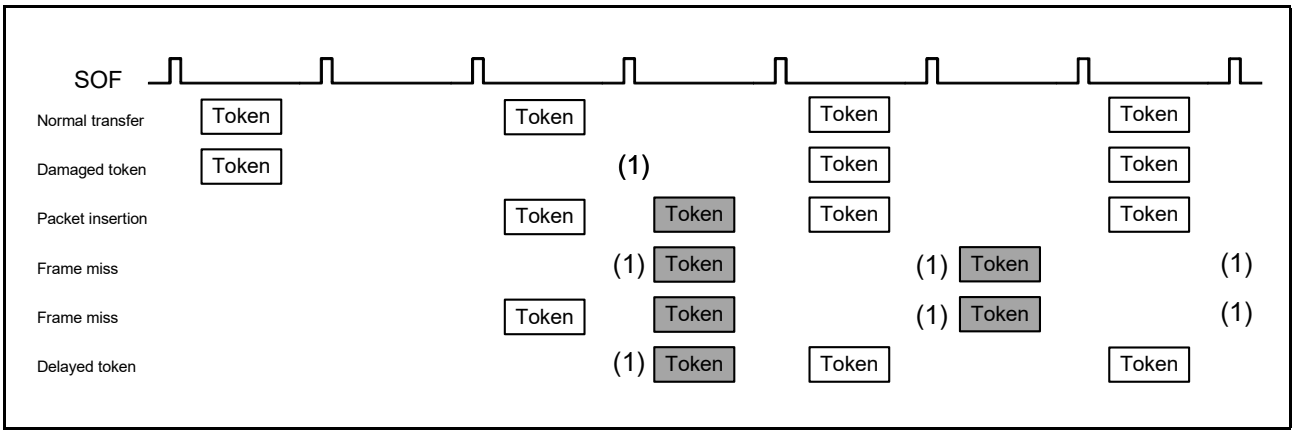

Figure 32.14 Example of Interval Error When IITV = 1

32.12 SOF Interpolation

If an SOF packet could not be received at intervals of 1 ms (in full-speed operation) or 125 µs (in high-speed operation) because of corruption or missing, this controller interpolates the SOF. The SOF interpolation operation begins when both the USBE and SUSPM bits have been set to 1 and an SOF packet is received. The interpolation is initialized under the following conditions.

(1) Hardware reset
(2) USB bus reset
(3) Suspended state detected

The SOF interpolation operates according to the following specifications.

(1) The frame interval (125 µs or 1 ms) is based on the results of the reset handshake protocol.
(2) The interpolation does not operate until the SOF packet is received.
(3) After a first SOF packet is received, interpolation of another SOF packet proceeds after a 125-µs or 1-ms interval counted in cycles of the internal clock running at 48 MHz clock has elapsed.
(4) Interpolation is performed in the previous reception intervals after the 2nd and subsequent SOF packets are received.
(5) Interpolation is not performed in the suspended state or during reception of a USB bus reset.
When the controller goes to the suspended state in high-speed operation, interpolation continues for 3 ms from the last packet.

The SOF interpolation works for the following.

(1) Updating of the frame number or micro-frame number
(2) SOFR interrupt and µSOF lock
(3) SOF pulse output
(4) Isochronous transfer interval count

When an SOF packet is lost during full-speed operation, the FRNM bit of the FRMNUM register is not updated.
When a µSOF packet is lost during high-speed operation, the UFRNM bit of the UFRMNUM register is updated. However, when a µSOF packet when µFRNM = 000b is lost, the FRNM bit is not updated. At this time, even if µSOF packets when µFRNM ≠ 000b are received successfully, the FRNM bit is not updated.

33. Serial Communications Interface with FIFO (SCIFA)

This LSI has five channels of serial communication interface (SCIFA) with FIFO that support both asynchronous and clock synchronous serial communication. The SCIFA has 16-stage FIFO buffers for transmission and reception, respectively, for each channel that enable this LSI to perform efficient high-speed continuous communication.

33.1 Overview

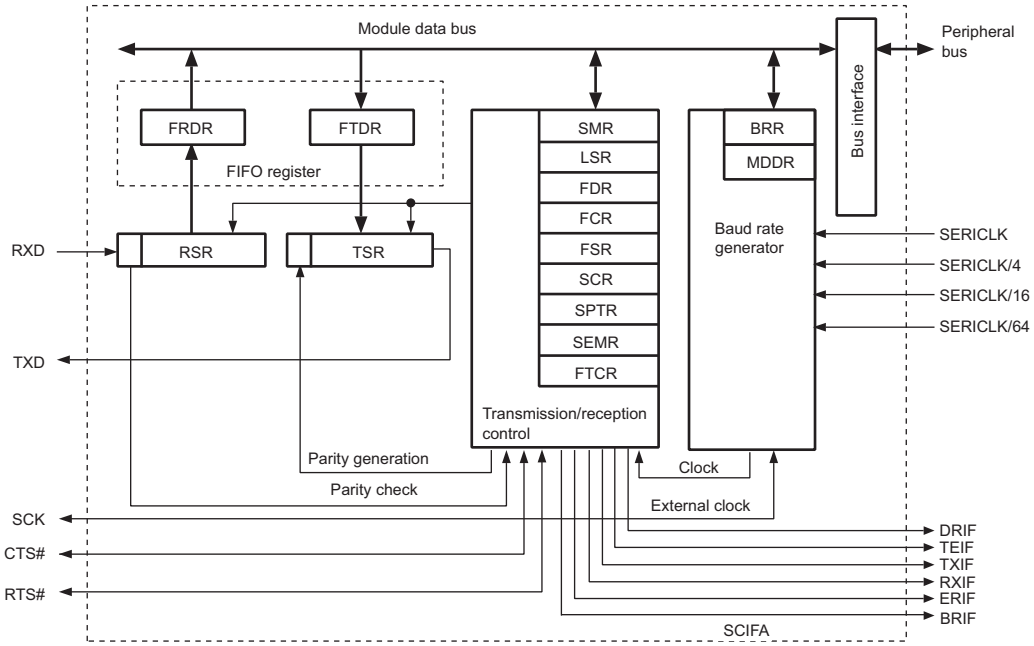
Table 33.1 lists the specifications of the SCIFA.

Table 33.1 Specifications of SCIFA

Item		Description
Channel		5 channels
Serial communication method		Asynchronous communication mode and clock synchronous communication mode
Transfer speed		Selectable bit rate with an on-chip baud rate generator
Full duplex communication		Transmitting section: realizes continuous data transmission using 16-stage FIFO buffer Receiving section: realizes continuous data reception using 16-stage FIFO buffer
Data transmission		Selectable either LSB-first or MSB-first transfer
Interrupt source		The following six sources: • Transmit-end (TEIF) • Transmit-FIFO-data-empty (TXIF) • Receive-FIFO-data-full (RXIF) • Receive-data-ready (DRIF)*1 • Framing error or parity error (ERIF) • Break or overrun (BRIF)
Asynchronous communication mode	Character length	7 or 8 bits
	Transmission stop bit length	1 or 2 bits
	Parity	Even, odd, or none
	Receive error detection	Detects following errors as receive error: parity error, overrun error, and framing error
	Hardware flow control	Controls data transmission and reception using the CTS# and RTS# pins.
	Break detection	Break signal detection function by hardware.
	Clock source	Selectable from internal or external clock
	Noise cancellation	Incorporates a digital noise filter in the RXD pin input path.
Clock synchronous communication mode	Character length	8 bits
	Receive error detection	Detects an overrun error as a receive error.
	Clock source	Selectable either internal or external clock
Bit rate modulation		Enables errors to be decreased by correcting the output of the on-chip baud rate generator.

Note 1. Effective only for asynchronous communication mode

Figure 33.1 shows a block diagram of the SCIFA.



RSR:	Receive shift register	BRR:	Bit rate register
FRDR:	Receive FIFO data register	SPTR:	Serial port register
TSR:	Transmit shift register	FCR:	FIFO control register
FTDR:	Transmit FIFO data register	FDR:	FIFO data count register
SMR:	Serial mode register	LSR:	Line status register
SCR:	Serial control register	SEMR:	Serial extended mode register
FSR:	Serial status register	FTCR:	FIFO trigger control register
MDDR:	Modulation duty register		

Figure 33.1 Block Diagram of SCIFA

Table 33.2 lists the input/output pins of the SCIFA.

Table 33.2 Pin Configuration of the SCIFA

Item	Pin Name	I/O	Function
Serial clock pin	SCK	I/O	Transmission/reception clock input/output, general output
Receive data pin	RXD	Input	Receive data input
Transmit data pin	TXD	Output	Transmit data output
Transmission/reception start control pin	CTS#	I/O	Input for hardware flow control (transmission enable signal) / general output
	RTS#	Output	Output for hardware flow control (transmission request signal) / general output

Note: Channels of each pin is omitted.

33.2 Register Descriptions

33.2.1 Receive Shift Register (RSR)

The RSR register receives serial data and temporally stores the data. The SCIFA stores the serial data input via the RXD pin into the RSR register. When one byte of data has been received, it is automatically transferred to the receive FIFO data register (FRDR).
The CPU cannot read from or write to the RSR register directly.

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

33.2.2 Receive FIFO Data Register (FRDR)

The FRDR register is an 8-bit, 16-stage FIFO register that stores the received serial data. When the SCIFA receives one byte of serial data, it transfers the received data from the receive shift register (RSR) to the FRDR register and completes the receive operation. Continuous reception is possible until the received 16 bytes of data are stored. If the FRDR register is read when there is no received data in the FRDR register, an undefined value is read.
When the FRDR register is full of received data, subsequently received serial data is lost.
The CPU can read the FRDR register but cannot write to it.

Address(es): SCIFA0.FRDR A006 500Ah, SCIFA1.FRDR A006 540Ah, SCIFA2.FRDR A006 580Ah, SCIFA3.FRDR A006 5C0Ah, SCIFA4.FRDR A006 600Ah

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

33.2.3 Transmit Shift Register (TSR)

The SCIFA transfers the transmit data from the transmit FIFO data register (FTDR) to the TSR register, and then transmits the data serially to the TXD pin. After transmitting one byte of data, the SCIFA automatically transfers the next transmit data from the FTDR register into the TSR register and starts transmission.
The CPU cannot read from or write to the TSR register directly.

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

33.2.4 Transmit FIFO Data Register (FTDR)

The FTDR register is an 8-bit, 16-stage FIFO register that stores serial transmission data. When the SCIFA detects that the transmit shift register (TSR) is empty, it transmits data written in the FTDR register to the TSR register and starts serial transmission. Continuous serial transmission is executed until there is no transmit data left in the FTDR register. Writing the transmit data to the FTDR register should be done when a transmit data empty interrupt (TXIF) request is generated.

When the FTDR register becomes full of transmit data (16 bytes), no more data can be written. Even if new data is written, the data is ignored.

CPU can read from the FTDR register but cannot write to it.

Address(es): SCIFA0.FTDR A006 5006h, SCIFA1.FTDR A006 5406h, SCIFA2.FTDR A006 5806h, SCIFA3.FTDR A006 5C06h, SCIFA4.FTDR A006 6006h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

33.2.5 Serial Mode Register (SMR)

The SMR register specifies the SCIFA serial communication format and selects the clock source for the baud rate generator.

The CPU can always read and write to the SMR register.

Address(es): SCIFA0.SMR A006 5000h, SCIFA1.SMR A006 5400h, SCIFA2.SMR A006 5800h, SCIFA3.SMR A006 5C00h, SCIFA4.SMR A006 6000h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CM	CHR	PE	PM	STOP	—	CKS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKS[1:0]	Clock Select	b1b0 0 0: 1 × SERICLK*1 0 1: 1/4 × SERICLK*1 1 0: 1/16 × SERICLK*1 1 1: 1/64 × SERICLK*1	R/W
b2	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b3	STOP	Stop Bit Length	0: One stop bit 1: Two stop bits	R/W
b4	PM	Parity Mode	0: Even parity 1: Odd parity	R/W
b5	PE	Parity Enable	0: Parity bit addition or check is disabled. 1: Parity bit addition or check is enabled.	R/W
b6	CHR	Character Length	0: 8-bit data 1: 7-bit data*2	R/W
b7	CM	Communication Mode	0: Asynchronous mode 1: Clock synchronous mode	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. SERICLK: Peripheral clock

Note 2. When 7-bit data is selected, the MSB (bit 7) of the transmit FIFO data register is not transmitted.

CKS[1:0] Bits (Clock Select)

Select an internal clock source for the on-chip baud rate generator. For further information on the clock source, bit rate register settings, and baud rates, see section 33.2.8, Bit Rate Register (BRR).

STOP Bit (Stop Bit Length)

Selects one bit or two bits as the stop bit length in asynchronous mode. This setting is used only in asynchronous mode. It is ignored in clock synchronous mode because no stop bits are added. When receiving, only the first stop bit is checked, regardless of the STOP bit setting. If the second stop bit is 1, it is treated as a stop bit, but if the second stop bit is 0, it is treated as the start bit of the next incoming character.

Note: When transmitting with one stop bit, a single 1 bit (stop bit) is added at the end of each transmission character.

Note: When transmitting with two stop bits, two 1 bits (stop bits) are added at the end of each transmission character.

PM Bit (Parity Mode)

Selects either the even or odd parity check. The setting of this bit is effective only when the parity enable (PE) bit of this register is set to 1 in asynchronous mode. The setting of this bit is ignored in clock synchronous mode, or when parity addition/check is disabled in asynchronous mode.

Note: If even parity is selected, the parity bit is added to data to be transmitted to make the total number of 1s even in the transmission character and parity bit combined. When receiving, the SCIFA verifies that the total number of 1s in the received character and parity bit combined is even.

Note: If odd parity is selected, the parity bit is added to data to be transmitted to make the total number of 1s odd in the transmission character and parity bit combined. When receiving, the SCIFA verifies that the total number of 1s in the received character and parity bit combined is odd.

PE Bit (Parity Enable)

Selects whether to add a parity bit on data transmission and whether to enable/disable the parity check on data reception in asynchronous mode. In clock synchronous mode, a parity bit is neither added nor checked, regardless of the setting of this bit.

Note: When this bit is set to 1, an even or odd parity bit specified in the PM bit is added to data to be transmitted. The SCIFA verifies whether the parity bit of the received data is even or odd as specified in the PM bit when receiving.

CHR Bit (Character Length)

Selects 7- or 8-bit data length in asynchronous mode. In clock synchronous mode, the data length is always 8 bits, regardless of the CHR setting.

CM Bit (Communication Mode)

Selects whether the SCIFA operates in asynchronous or clock synchronous mode.

33.2.6 Serial Control Register (SCR)

The SCR register enables or disables the SCIFA transmission/reception and interrupt requests, and selects the transmit/receive clock source. The CPU can always read from and write to the SCR register.

Address(es): SCIFA0.SCR A006 5004h, SCIFA1.SCR A006 5404h, SCIFA2.SCR A006 5804h, SCIFA3.SCR A006 5C04h, SCIFA4.SCR A006 6004h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TIE	RIE	TE	RE	REIE	TEIE	CKE[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	CKE[1:0]	Clock Enable	In asynchronous mode: b1 b0 0 0: Internal clock or SCK pin is used for input pin (input signal is ignored). The SCK pin state depends on the SCKIO and SCKDT bits in SPTR. 0 1: Internal clock or SCK pin is used for clock output (The output clock frequency is 16 or 8 times of the bit rate). 1 0: External clock or SCK pin is used for clock input (The input clock frequency is 16 or 8 times of the bit rate). 1 1: Setting prohibited In clock synchronous mode: b1 b0 0 0: Internal clock or SCK pin is used for synchronous clock output. 0 1: Internal clock or SCK pin is used for synchronous clock output. 1 0: External clock or SCK pin is used for synchronous clock input. 1 1: Setting prohibited	R/W
b2	TEIE*1	Transmit End Interrupt Enable	0: Transmit end interrupt (TEIF) request is disabled. 1: Transmit end interrupt (TEIF) request is enabled.	R/W
b3	REIE	Receive Error Interrupt Enable	0: Receive-error interrupt (ERIF) and break interrupt (BRIF) requests are disabled. 1: Receive-error interrupt (ERIF) and break interrupt (BRIF) requests are enabled.	R/W
b4	RE	Receive Enable	0: Data reception is disabled. 1: Data reception is enabled.	R/W
b5	TE	Transmit Enable	0: Data transmission is disabled. 1: Data transmission is enabled.	R/W
b6	RIE	Receive Interrupt Enable	0: Receive-FIFO-data-full interrupt (RXIF), receive-data ready interrupt (DRIF), receive-error interrupt (ERIF), and break interrupt (BRIF) requests are disabled. 1: Receive-FIFO-data-full interrupt (RXIF), receive-data ready interrupt (DRIF), receive-error interrupt (ERIF), and break interrupt (BRIF) requests are enabled.	R/W
b7	TIE	Transmit Interrupt Enable	0: Transmit-FIFO-data-empty interrupt request (TXIF) is disabled. 1: Transmit-FIFO-data-empty interrupt request (TXIF) is enabled.	R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. TEIF interrupt requests can be cleared by reading 1 from the TEND flag, and then clearing the setting to 0, or by setting the TEIE bit to 0.

CKE[1:0] Bits (Clock Enable)

Select the SCIFA clock source and enable or disable clock output from the SCK pin. Depending on the settings of these bits, the SCK pin can be used for serial clock output or serial clock input. If the SCK pin is set for the synchronous clock output in the clock synchronous mode, set the CM bit in the SMR register to 1, and then set the CKE[1:0] bits. The settings of the CKE[1:0] bits are listed in Table 33.15.

REIE Bit (Receive Error Interrupt Enable)

Specifies whether to enable or disable a receive-error interrupt (ERIF) request and a break interrupt (BRIF) request. The setting of this bit is only valid when the RIE bit is set to 0.

Note: ERIF interrupt requests can be cleared by reading 1 from the ER bit in the FSR register, and then clearing the setting to 0, or by clearing both the RIE and REIE bits in this register to 0. BRIF interrupt requests can be cleared by reading 1 from the BRK bit in the FSR register, or from the ORER flag in the LSR register, and then clearing the setting to 0, or by clearing both the RIE and REIE bits in this register to 0.

RE Bit (Receive Enable)

Specifies whether to enable or disable the serial data reception.

Note: Setting this bit to 0 does not affect the receive flags (DR, ER, BRK, RDF, FER, and PER in the FSR register, and ORER in the LSR register). These flags retain their previous values.

Note: Serial reception starts when a start bit is detected in asynchronous mode, or a synchronous clock input is detected in clock synchronous mode. Before setting this bit to 1, be sure to set the serial mode register (SMR) and the FIFO control register (FCR) to select the receive format and reset the receive FIFO.

TE Bit (Transmit Enable)

Specifies whether to enable or disable the serial data transmission.

Note: Serial transmission starts after writing of data to be transmitted into the FTDR register under this condition. Before setting this bit to 1, be sure to set the serial mode register (SMR) and the FIFO control register (FCR) to select the transmit format and reset the transmit FIFO.

RIE Bit (Receive Interrupt Enable)

Specifies whether to enable or disable a receive-FIFO-data-full (RXIF) interrupt request when the RDF flag in the serial status register (FSR) is set to 1, a receive-data ready (DRIF) interrupt request when the DR flag in the FSR register is set to 1, a receive-error (ERIF) interrupt request when the ER flag in the FSR register is set to 1, and a break (BRIF) interrupt request when the BRK flag in the FSR register or the ORER flag in the line status register (LSR) is set to 1.

Note: RXIF interrupt requests can be cleared by reading 1 from the DR or RDF flag in the FSR register, then clearing the flag to 0, or by clearing the RIE bit to 0. DRIF interrupt requests can be cleared by reading 1 from the DR flag in the FSR register, and then clearing the setting to 0, or by clearing the RIE bit in this register to 0. Receive error interrupt (ERIF) requests and break interrupt (BRIF) requests can be cleared by clearing both the RIE and REIE bits in this register to 0.

TIE Bit (Transmit Interrupt Enable)

Specifies whether to enable or disable a transmit-FIFO-data-empty interrupt (TXIF) request when the serial transmit data is transferred from the transmit FIFO data register (FTDR) into the transmit shift register (TSR), the quantity of data in the transmit FIFO data register falls below the specified trigger number for transmission, and the TDFE flag in the serial status register (FSR) is set to 1.

Note: TXIF interrupt requests can be cleared either by writing a greater quantity of transmit data than the specified transmission trigger number into the FTDR register, reading 1 from the TDFE flag, and then clearing the TDFE flag to 0, or by clearing this bit to 0.

33.2.7 Serial Status Register (FSR)

The FSR register is a 16-bit register. The 8 lower-order bits indicate the status flag representing the SCIFA operating state.

The CPU can always read and write to the FSR register, but cannot write 1 to the status flags (ER, TEND, TDFE, BRK, RDF, and DR bits) in this register. These flags can be only cleared to 0 when they have first been read (after being set to 1). b3 (FER) and b2 (PER) are read-only bits that cannot be written.

Address(es): SCIFA0.FSR A006 5008h, SCIFA1.FSR A006 5408h, SCIFA2.FSR A006 5808h, SCIFA3.FSR A006 5C08h, SCIFA4.FSR A006 6008h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	ER	TEND	TDFE	BRK	FER	PER	RDF	DR
Value after reset:	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DR	Receive Data Ready Flag	0: Reception is in progress, or no received data has remained in the FRDR register after normally completed receiving. 1: Next receive data has not been received.	R/(W) *1
b1	RDF	Receive FIFO Data Full Flag	0: The quantity of receive data in the FRDR register falls below the specified reception trigger number. 1: The quantity of receive data written in the FRDR register is equal to or greater than the specified reception trigger number.	R/(W) *1
b2	PER	Parity Error Flag	0: No receive parity error occurred in the next receive data read from the FRDR register. 1: A receive parity error occurred in the next receive data read from the FRDR register.	R
b3	FER	Framing Error Flag	0: No receive framing error occurred in the next data read from the FRDR register. 1: A receive framing error occurred in the next data read from the FRDR register.	R
b4	BRK	Break Detect Flag	0: No break signal is received. 1: A break signal is received.*2	R/(W) *1
b5	TDFE	Transmit FIFO Data Empty Flag	0: The quantity of transmit data written in the FTDR register exceeds the specified transmission trigger number. 1: The quantity of transmit data written in the FTDR register is equal to or less than the specified transmission trigger number.*3	R/(W) *1
b6	TEND	Transmit End Flag	0: Transmission is in the waiting state or in progress. 1: Transmission is completed.	R/(W) *1
b7	ER	Receive Error Flag	0: Reception is in progress or has normally completed. 1: A framing error or parity error has occurred during reception.	R/(W) *1
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. 0 can be only written to clear the flag after 1 is read.

Note 2. When a break signal is detected, transfer of the receive data (00h) to the FRDR register stops after the detection. When the break ends and the receive signal becomes mark state (high level), the transfer of receive data resumes.

Note 3. Since the FTDR register is a 16-byte FIFO register, the maximum quantity of data that can be written when TDFE is 1 is “16 minus the number of non-transmitted data units”. If additional data is written, the data is ignored. The quantity of data in the FTDR register is indicated by the 8 higher-order bits of the FDR register.

DR Bit (Receive Data Ready Flag)

Indicates that the quantity of data stored in the receive FIFO data register (FRDR) falls below the specified reception trigger number, and that no next data has been received yet after the elapse of 15 ETUs*1 from the last stop bit in asynchronous mode. In clock synchronous mode, this bit is not set to 1.

[Setting condition]

- DR is set to 1 when the FRDR register contains less data than the specified reception trigger number*2, and no next data has been received yet after the elapse of 15 ETUs*1 from the last stop bit.

[Clearing conditions]

When either of the following is satisfied:

- DR is cleared to 0 when DR = 1 is read and then 0 is written to the DR flag.
- DR is cleared to 0 when all received data in the FRDR register are read.

Note 1. This is equivalent to one and a half (1.5) frames in the 8-bit format with one stop bit (ETU: elementary time unit).
Note 2. The clearing condition takes precedence when all received data in the FRDR register are read.
Note: When the RE bit in SCR is cleared to 0, the DR bit is not affected and retains its previous value.

RDF Bit (Receive FIFO Data Full Flag)

Indicates that receive data has been transferred to the receive FIFO data register (FRDR), and the quantity of data in FRDR becomes equal to or greater than the specified reception trigger number.

[Setting condition]

- RDF is set to 1 when the quantity of receive data which is equal to or greater than the specified reception trigger number are stored in the FRDR register*1.

[Clearing condition]

- RDF is cleared to 0 when the FRDR register is read until the quantity of receive data in the FRDR register falls below the specified reception trigger number after 1 is read from RDF and then 0 is written to this bit.

Note 1. Since the FRDR register is a 16-byte FIFO register, the maximum quantity of data that can be read when this bit is 1 is equivalent to the specified reception trigger number. If an attempt is made to read after all the data in the FRDR register has been read, the read data is undefined. The quantity of receive data in the FRDR register is indicated by the 8 lower-order bits of the FDR register.

PER Bit (Parity Error Flag)

Indicates whether there is a parity error in the data read from the receive FIFO data register (FRDR) in asynchronous mode.

[Setting condition]

- PER is set to 1 when a parity error is present in the next data read from the FRDR register.

[Clearing condition]

- PER is cleared to 0 when no parity error is present in the next data read from the FRDR register.

FER Bit (Framing Error Flag)

Indicates whether there is a framing error in the data read from the receive FIFO data register (FRDR) in asynchronous mode.

[Setting condition]

- FER is set to 1 when a framing error is present in the next data read from the FRDR register.

[Clearing condition]

- FER is cleared to 0 when no framing error is present in the next data read from the FRDR register.

BRK Bit (Break Detect Flag)

Indicates that a break signal has been detected in receive data.

[Setting condition]

- BRK is set to 1 when data including a framing error is received, and the framing error is followed by at least one frame of data received at the space 0 level (low level).

[Clearing condition]

- BRK is cleared to 0 when software reads BRK after it has been set to 1 and then writes 0 to BRK.

TDFE Bit (Transmit FIFO Data Empty Flag)

Indicates that data has been transferred from the transmit FIFO data register (FTDR) into the transmit shift register (TSR), the quantity of data in the FTDR register becomes equal to or less than the specified transmission trigger number, and writing of transmit data to the FTDR register is enabled.

[Setting conditions]

When either of the following is satisfied:

- TDFE is set to 1 when the TE bit in SCR is 0.
- TDFE is set to 1 when the quantity of transmit data written in the FTDR register is equal to or less than the specified transmission trigger number.

[Clearing condition]

- TDFE is cleared to 0 when 0 is written in the TDFE bit after reading TDFE = 1.

TEND Bit (Transmit End Flag)

Indicates that the FTDR register contains no more valid data and transmission is completed when transmitting the last bit of the transmit data.

[Setting condition]

- TEND is set to 1 when the FTDR register does not contain transmit data when the last bit of the serial transmission data is transmitted.

[Clearing conditions]

When either of the following is satisfied:

- When transmit data is written to the FTDR register
- When 0 is written to TEND after it has been read as 1

ER Bit (Receive Error Flag)

Indicates the occurrence of a framing error, or of a parity error when receiving the parity-added data*1.

[Setting conditions]

When either of the following is satisfied:

- ER is set to 1 when the stop bit is found to be 0 after checking whether the stop bit of the received data is 1 at the end of one data receive operation*2.
- ER is set to 1 when the total number of 1s in the received data and parity bit combined does not match the even or odd parity setting specified by the PM bit in the SMR register.

[Clearing condition]

- When 0 is written to ER after it has been read as 1

Note 1. Clearing the RE bit to 0 in the SCR register does not affect this bit, which retains its previous value. Even if a receive error occurs, the receive data is transferred to the FRDR register and the receive operation is continued. Whether the data read from the FRDR register includes a receive error can be detected by the FER and PER bits in the FSR register.

Note 2. In two stop bits mode, only the first stop bit is checked; the second stop bit is not checked.

33.2.8 Bit Rate Register (BRR)

The BRR register is an 8-bit register that, together with the baud rate generator clock source selected by the CKS[1:0] bits in the serial mode register (SMR), determines the serial transmit/receive bit rate.
This register is located in the same address as that of the MDDR register and selected when the MDDRS bit in SEMR is 0. The CPU can read and write to BRR. Writing to BRR should be executed when TE = RE = 0 in the SCR register.

Address(es): SCIFA0.BRR A006 5002h, SCIFA1.BRR A006 5402h, SCIFA2.BRR A006 5802h, SCIFA3.BRR A006 5C02h, SCIFA4.BRR A006 6002h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The BRR setting is calculated using the following formulae.
[Asynchronous mode]

- When the baud rate generator is in normal mode (SEMR.BGDM = 0):

$$N = \frac{SERICLK}{64 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$N = \frac{SERICLK}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1):

$$N = \frac{SERICLK}{32 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$N = \frac{SERICLK}{16 \times 2^{2n-1} \times B} \times 10^6 - 1$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

[Clock synchronous mode]

$$N = \frac{SERICLK}{8 \times 2^{2n-1} \times B} \times 10^6 - 1$$

B: Bit rate (bit/s)
N: Setting of the BRR register (0 ≤ N ≤ 255) (The setting must satisfy the electrical characteristics).
SERICLK: Operating frequency for peripheral modules (MHz)
n: Baud rate generator clock source (n = 0, 1, 2, 3) (For the clock sources and values of n, see Table 33.3).

Note: The MDDR register is used to adjust the bit rate. For details, see section 33.2.9, Modulation Duty Register (MDDR).

Table 33.3 SMR Register Setting

		Setting of SMR.CKS [1:0] Bits	
n	**Clock Source**	**b1**	**b0**
0	SERICLK	0	0
1	SERICLK/4	0	1
2	SERICLK/16	1	0
3	SERICLK/64	1	1

The bit rate error in asynchronous mode is calculated using the following formulae.

- When the baud rate generator is in normal mode (SEMR.BGDM = 0):

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{(N + 1) \times B \times 64 \times 2^{2n-1}} - 1 \right\} \times 100$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{(N + 1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1):

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{(N + 1) \times B \times 32 \times 2^{2n-1}} - 1 \right\} \times 100$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{(N + 1) \times B \times 16 \times 2^{2n-1}} - 1 \right\} \times 100$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

Table 33.4 list the examples of the BRR register setting in asynchronous mode, and Table 33.5 list the examples of the BRR register setting in clock synchronous mode.

Table 33.4 Bit Rates and BRR Register Settings in Asynchronous Mode

Bit Rate (bps)	SERICLK (MHz)					
	120			150		
	n	N	Error (%)	n	N	Error (%)
150						
300	3	194	0.16	3	243	0.06
600	3	97	-0.35	3	121	0.06
1200	2	194	0.16	2	243	0.06
2400	2	97	-0.35	2	121	0.06
4800	1	194	0.16	1	243	0.06
9600	1	97	-0.35	1	121	0.06
14400	1	64	0.16	1	80	0.47
19200	0	194	0.16	0	243	0.06
28800	0	129	0.16	0	162	-0.15
31250	0	119	0	0	149	0
38400	0	97	-0.35	0	121	0.06
115200				0	40	-0.76
500000						

Note: These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 0. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1, the bit rate is doubled. When bits SEMR.ABCS0 and SEMR.BGDM are both 1, the bit rate is quadrupled. Configure settings so the range of error is no greater than 1%.
Values for the blank cells in the table can be set using the MDDR register. For details, see section 33.2.9, Modulation Duty Register (MDDR) and the Table 33.10.

Table 33.5 Bit Rates and BRR Register Settings in Clock Synchronous Mode

Bit Rate (bps)	SERICLK (MHz)			
	120		150	
	n	N	n	N
250				
500				
1000				
2500	3	187	3	233
5000	3	93	3	116
10000	2	187	2	233
25000	2	74	2	93
50000	1	149	1	187
100000	1	74	1	93
250000	0	119	0	149
500000	0	59	0	74
1000000	0	29	0	37
2500000	0	11	0	14
5000000	0	5	0	7

Blank: Setting is prohibited.
Note: Set the BRR register so that the range of error can fall within 1% or less.

Table 33.6 lists the maximum bit rates for various frequencies in asynchronous mode when the baud rate generator is used. Table 33.7 lists the maximum bit rates for various frequencies in clock synchronous mode when the baud rate generator is used. Table 33.8 and Table 33.9 list the maximum rates for external clock inputs in asynchronous mode and clock synchronous mode, respectively.

Table 33.6 Maximum Bit Rates for Various Frequencies with Baud Rate Generator (in Asynchronous Mode)

SERICLK (MHz)	Maximum Bit Rate (bit/s)	Settings	
		n	N
120	15000000	0	0
150	18750000	0	0

Note: These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 1. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1, the bit rate is 1/2. When bits SEMR.ABCS0 and SEMR.BGDM are both 0, the bit rate is 1/4.

Table 33.7 Maximum Bit Rates for Various Frequencies with Baud Rate Generator (in Clock Synchronous Mode)

SERICLK (MHz)	Discontinuous Transmission/Reception			Continuous Transmission/Reception		
	Maximum Bit Rate (bit/s)	Settings		Maximum Bit Rate (bit/s)	Settings	
		n	N		n	N
120	30000000	0	0	15000000	0	1
150	37500000	0	0	18750000	0	1

Table 33.8 Maximum Bit Rates with External Clock Input (in Asynchronous Mode)

SERICLK (MHz)	External Input Clock (MHz)	Maximum Bit Rate (bit/s)
120	30	3750000
150	37.5	4687500

Note: This is an example when the SEMR.ABCS0 bit is 1. When the ABCS0 bit is set to 0, the bit rate is 1/2 .

Table 33.9 Maximum Bit Rates with External Clock Input (in Clock Synchronous Mode)

SERICLK (MHz)	External Input Clock (MHz)	Maximum Bit Rate (bit/s)
120	10	10000000
150	12.5	12500000

33.2.9 Modulation Duty Register (MDDR)

The MDDR register corrects the bit rate adjusted by the BRR register. The value after reset of this register is FFh. When the BRME bit in SEMR is set to 1, the bit rate generated by the on-chip baud rate generator is evenly corrected according to the settings of MDDR (MDDR/256). The relationship between the MDDR register setting and the bit rate (B) is given by the following formula. The MDDR register is located in the same address as that of the BRR register and is selected when the MDDRS bit in SEMR is 1. This register is only writable when TE = RE = 0 in the SCR register. b7 in this register is fixed to 1.

Address(es): SCIFA0.MDDR A006 5002h, SCIFA1.MDDR A006 5402h, SCIFA2.MDDR A006 5802h, SCIFA3.MDDR A006 5C02h, SCIFA4.MDDR A006 6002h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

The formulae below show the relationships between the MDDR setting and the bit rate (B) when the bit rate modulation function is used.

[Asynchronous mode]

- When the baud rate generator is in normal mode (SEMR.BGDM = 0):

$$B = \frac{SERICLK \times 10^6}{64 \times 2^{2n-1} \times (256/MDDR) \times (N + 1)}$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$B = \frac{SERICLK \times 10^6}{32 \times 2^{2n-1} \times (256/MDDR) \times (N + 1)}$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1):

$$B = \frac{SERICLK \times 10^6}{32 \times 2^{2n-1} \times (256/MDDR) \times (N + 1)}$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$B = \frac{SERICLK \times 10^6}{16 \times 2^{2n-1} \times (256/MDDR) \times (N + 1)}$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

[Clock synchronous mode]

$$B = \frac{SERICLK \times 10^6}{8 \times 2^{2n-1} \times (256/MDDR) \times (N + 1)}$$

When the bit rate modulation is used, the bit rate average error is given by the following formulae.

- When the baud rate generator is in normal mode (SEMR.BGDM = 0):

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{B \times 64 \times 2^{2n-1} \times (256/\text{MDDR}) \times (N+1)} - 1 \right\} 100$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/\text{MDDR}) \times (N+1)} - 1 \right\} 100$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

- When the baud rate generator is in double-speed mode (SEMR.BGDM = 1):

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{B \times 32 \times 2^{2n-1} \times (256/\text{MDDR}) \times (N+1)} - 1 \right\} 100$$

(When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0))

$$\text{Error (\%)} = \left\{ \frac{\text{SERICLK} \times 10^6}{B \times 16 \times 2^{2n-1} \times (256/\text{MDDR}) \times (N+1)} - 1 \right\} 100$$

(When operating on the base clock with a frequency 8 times the bit rate (SEMR.ABCS0 = 1))

B:	Bit rate (bits/s)
N:	BRR register setting (0 ≤ N ≤ 255) (The setting must satisfy the electrical characteristics).
SERICLK:	Operating frequency for peripheral modules (MHz)
MDDR:	MDDR setting (128 ≤ MDDR ≤ 255)
n:	Baud rate generator clock source (n = 0, 1, 2, 3) (For the clock sources and values of n, see Table 33.3).

Table 33.10 Bit Rates and Settings of BRR and MDDR Registers in Asynchronous Mode

Bit Rate (bps)	SERICLK (MHz)							
	120				150			
	n	N	MDDR	Error (%)	n	N	MDDR	Error (%)
150	3	205	135	-0.003	3	247	130	-0.018
300	3	176	232	0.001	3	205	216	-0.003
600	2	205	135	-0.003	3	102	216	-0.003
1200	2	176	232	0.001	2	205	216	-0.003
2400	1	205	135	-0.003	2	102	216	-0.003
4800	1	176	232	0.001	1	205	216	-0.003
9600	0	205	135	-0.003	1	102	216	-0.003
14400	0	176	174	0.001	0	205	162	-0.003
19200	0	176	232	0.001	0	205	216	-0.003
28800	0	117	232	0.001	0	102	162	-0.003
31250	0	59	128	0.000	0	74	128	0.000
38400	0	73	194	0.007	0	102	216	-0.003
115200	0	21	173	-0.009	0	23	151	0.003
500000	0	6	239	0.028	0	6	151	-0.077

Note: These values assume bits SEMR.ABCS0 and SEMR.BGDM are both 0. When either the SEMR.ABCS0 bit or SEMR.BGDM bit is set to 1, the bit rate is doubled. When bits SEMR.ABCS0 and SEMR.BGDM are both 1, the bit rate is quadrupled. Configure settings so the range of error is no greater than 1%.

33.2.10 FIFO Control Register (FCR)

The FCR register resets the quantity of data in the transmit FIFO data register (FTDR) and the receive FIFO data register (FRDR) and specifies the number of triggers. This register also specifies whether to enable the loop-back test.
The CPU can always read and write to the FCR register.

Address(es): SCIFA0.FCR A006 500Ch, SCIFA1.FCR A006 540Ch, SCIFA2.FCR A006 580Ch, SCIFA3.FCR A006 5C0Ch, SCIFA4.FCR A006 600Ch

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	RSTRG[2:0]			RTRG[1:0]		TTRG[1:0]		MCE	TFRST	RFRST	LOOP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LOOP	Loop-Back Test	0: Loop back test is disabled. 1: Loop back test is enabled.	R/W
b1	RFRST	Receive FIFO Data Register Reset	0: Normal operation 1: Resets the FRDR register.	R/W
b2	TFRST	Transmit FIFO Data Register Reset	0: Normal operation 1: Resets the FTDR register.	R/W
b3	MCE	Modem Control Enable	0: Modem signal is disabled.*1 1: Modem signal is enabled.	R/W
b5, b4	TTRG[1:0]	Transmit FIFO Data Trigger Number Select	b5 b4 0 0: 8 (8)*2 0 1: 4 (12)*2 1 0: 2 (14)*2 1 1: 0 (16)*2	R/W
b7, b6	RTRG[1:0]	Receive FIFO Data Trigger Number Select	In asynchronous mode: b7 b6 0 0: 1 0 1: 4 1 0: 8 1 1: 14 In clock synchronous mode: b7 b6 0 0: 1 0 1: 2 1 0: 8 1 1: 14	R/W
b10 to b8	RSTRG[2:0]	RTS# Output Active Trigger Number Select	b10 b8 0 0 0: 15 0 0 1: 1 0 1 0: 4 0 1 1: 6 1 0 0: 8 1 0 1: 10 1 1 0: 12 1 1 1: 14	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. The CTS# input level does not affect the transmit operation. Similarly, the RTS# input level does not affect the receive operation.
Note 2. Values in parentheses mean the number of empty bytes in the FTDR register when the TDFE flag is set to 1 and a transmit FIFO data empty interrupt (TXIF) request is generated.

LOOP Bit (Loop-Back Test)

Internally connects between the transmit output pin (TXD) and the receive input pin (RXD) and between the RTS# pin and the CTS# pin, to perform loop-back testing.

RFRST Bit (Receive FIFO Data Register Reset)

Disables the receive data in the receive FIFO data register (FRDR) and makes the data to the empty state. If you set this bit to 1, be sure to clear it to 0 afterward.

TFRST Bit (Transmit FIFO Data Register Reset)

Disables the transmit data in the transmit FIFO data register (FTDR) and makes the data to the empty state. If you set this bit to 1, be sure to clear it to 0 afterward.

MCE Bit (Modem Control Enable)

Specifies whether to enable or disable the modem control signals, CTS# and RTS#.
In clock synchronous mode, this bit should always be set to 0.

TTRG[1:0] Bits (Transmit FIFO Data Trigger Number Select)

Specify the reference quantity of data for transmission (i.e., the threshold number of entries to trigger the writing of further data for transmission) for setting of the TDFE flag in the serial status register (FSR). When the number of entries for transmission in the transmission FIFO, i.e. the number of entries written to the transmit FIFO data register (FTDR) that are yet to be transmitted, falls to or below the number specified by the TTRG[1:0] bits, the TDFE flag is set to 1 and a transmit FIFO data empty interrupt (TXIF) request is generated.
The setting in these bits is valid when the TTRGS bit in the FTCR register is 0. When the TTRGS bit in the FTCR register is 1, the setting of the TFTC[4:0] bits in the FTCR register is valid.

RTRG[1:0] Bits (Receive FIFO Data Trigger Number Select)

Specify the reference quantity of receive data (i.e., the threshold number of entries to trigger the reading of received data) for setting of the RDF flag in the serial status register (FSR). When the number of entries in the reception FIFO, i.e. the number of entries yet to be read from the receive FIFO data register (FRDR), rises to or above the number specified by the RTRG[1:0] bits, the RDF flag is set to 1 and a receive FIFO data full interrupt (RXIF) request is generated.
The setting in these bits is valid when the RTRGS bit in the FTCR register is 0. When the RTRGS bit in the FTCR register is 1, the setting of the RFTC[4:0] bits in the FTCR register is valid.

RSTRG[2:0] Bits (RTS# Output Active Trigger Number Select)

When the number of entries in the reception FIFO, i.e. the number of entries yet to be read from the receive FIFO data register (FRDR), rises to or above the trigger number specified by the RSTRG[2:0] bits, the RTS# signal is in the high state.
The setting in these bits is only valid when a modem signal is enabled by the MCE bit in this register in asynchronous mode.

33.2.11 FIFO Data Count Register (FDR)

The FDR register indicates the quantity of data stored in the transmit FIFO data register (FTDR) and the receive FIFO data register (FRDR).

This register indicates the quantity of transmit data in the FTDR register with the 8 higher-order bits, and the quantity of receive data in the FRDR register with the 8 lower-order bits. The CPU can always read the FDR register but cannot write to it.

Address(es): SCIFA0.FDR A006 500Eh, SCIFA1.FDR A006 540Eh, SCIFA2.FDR A006 580Eh, SCIFA3.FDR A006 5C0Eh, SCIFA4.FDR A006 600Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	T[4:0]					—	—	—	R[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	R[4:0]	Receive Data Quantity in FRDR	Indicate the quantity of receive data stored in the FRDR register.	R
b7 to b5	—	Reserved	These bits are read as 0.	R
b12 to b8	T[4:0]	Non-Transmitted Data Quantity in FTDR	Indicate the quantity of non-transmitted data stored in the FTDR register.	R
b15 to b13	—	Reserved	These bits are read as 0.	R

R[4:0] Bits

Indicate the quantity of receive data stored in the FRDR register.

00h means no received data, and 10h means that all of the received data is stored in the FRDR register.

T[4:0] Bits

Indicate the quantity of non-transmitted data stored in the FTDR register.

00h means no transmit data, and 10h means that all of the data for transmission is stored in the FTDR register.

33.2.12 Serial Port Register (SPTR)

The SPTR register controls input/output and data of the pins multiplexed to SCIFA function.
The CPU can always read and write to the SPTR register.

Note: b6, b4, b2, and b0 of this register respectively indicate the input status of their corresponding pins. See the descriptions for each bit for details. Writings to these bits in 1-bit unit are handled as read-modify-write, which may lead to undesired values to be written. To avoid this, when modifying the SPB2DT or SPB2IO bit, for example, write the other bit (the bit used in combination) at the same time.

Address(es): SCIFA0.SPTR A006 5010h, SCIFA1.SPTR A006 5410h, SCIFA2.SPTR A006 5810h, SCIFA3.SPTR A006 5C10h, SCIFA4.SPTR A006 6010h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	RTS2IO	RTS2DT	CTS2IO	CTS2DT	SCKIO	SCKDT	SPB2IO	SPB2DT
Value after reset:	0	0	0	0	0	0	0	0	0	x	0	x	0	x	0	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	SPB2DT	Serial Port Break Data Select	Controls the TXD pin in combination with the TE bit in the SCR register and the SPB2IO bit. See Table 33.13.	R/W
b1	SPB2IO	Serial Port Break Input/Output	Controls the TXD pin in combination with the TE bit in the SCR register and the SPB2DT bit.	R/W
b2	SCKDT	SCK Port Data Select	Controls the SCK pin in combination with the CM bit in the SMR register, the SCKIO bit, and the CKE1 and CKE0 bits in the SCR register. See Table 33.15.	R/W
b3	SCKIO	SCK Port Input/Output	Controls the SCK pin in combination with the CM bit in the SMR register, the SCKDT bit, and the CKE1 and CKE0 bits in the SCR register. See Table 33.15.	R/W
b4	CTS2DT	CTS# Port Data Select	Controls the CTS# pin in combination with MCE bit in FCR and CTS2IO bit. See Table 33.12.	R/W
b5	CTS2IO	CTS# Port Output Specify		R/W
b6	RTS2DT	RTS# Port Data Select	Controls the RTS# pin in combination with MCE bit in FCR and RTS2IO bit. See Table 33.11.	R/W
b7	RTS2IO	RTS# Port Output Specify		R/W
b15 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPB2DT Bit (Serial Port Break Data Select)

This bit specifies the output level of the TXD pin when the setting of the SCR.TE bit is 0. The RXD pin input status can be read from this bit regardless of the SPB2IO bit setting. However, the RXD pin function must have been selected with the multi-function pin controller (MPC).

SPB2IO Bit (Serial Port Break Input/Output)

Controls the TXD pin in combination with the TE bit in the SCR register and the SPB2DT bit.

SCKDT Bit (SCK Port Data Select)

The SCK pin status can be read from this bit regardless of the SCKIO bit setting. (When the SCK pin is used for input, the input signal is invalid (has no means) but the pin status can be read.) However, the SCK pin function must have been selected with the multi-function pin controller (MPC).

SCKIO Bit (SCK Port Input/Output)

Specifies input or output status of the SCK pin. This bit controls the SCK pin in combination with the SCKDT bit, the CM bit in the SMR register, and the CKE1 and CKE0 bits in the SCR register.

CTS2DT Bit (CTS# Port Data Select)

The status of the CTS# pin can be read from this bit regardless of the CTS2IO bit setting. However, the CTS# pin function must have been selected with the multi-function pin controller (MPC).

RTS2DT Bit (RTS# Port Data Select)

The status of the RTS# pin can be read from this bit regardless of the RTS2IO bit setting. However, the RTS# pin function must have been selected with the multi-function pin controller (MPC).

Table 33.11 RTS# Pin Status

FCR.MCE Bit Setting	RTS2IO Bit Setting	RTS2DT Bit Setting	RTS# Pin Status
0	0	×	Setting prohibited*1
0	1	0	Low output
0	1	1	High output
1	×	×	Modem control output

×: Don't care

Note 1. There is no problem with the initial setting if the RTS# pin is not used.

Table 33.12 CTS# Pin Status

FCR.MCE Bit Setting	CTS2IO Bit Setting	CTS2DT Bit Setting	CTS# Pin Status
0	0	×	Setting prohibited*1
0	1	0	Low output
0	1	1	High output
1	×	×	Modem control input

×: Don't care

Note 1. There is no problem with the initial setting if the CTS# pin is not used.

Table 33.13 TXD Pin Status

SCR.TE Bit Setting	SPB2IO Bit Setting	SPB2DT Bit Setting	TXD Pin Status
0	0	×	Setting prohibited
0	1	0	Low output
0	1	1	High output
1	×	×	Transmit data output

×: Don't care

33.2.13 Line Status Register (LSR)

The LSR register is a 16-bit register. The PER and FER bits indicate the number of receive errors in the receive FIFO data register. 1 cannot be written to the ORER status flag. The flag should be read as 1 prior to clearing it to 0.

Address(es): SCIFA0.LSR A006 5012h, SCIFA1.LSR A006 5412h, SCIFA2.LSR A006 5812h, SCIFA3.LSR A006 5C12h, SCIFA4.LSR A006 6012h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	PER[3:0]				—	—	FER[3:0]				—	ORER
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ORER	Overrun Error Flag	0: Reception is in progress or has normally completed. 1: An overrun error has occurred during reception.	R/(W) *1
b1	—	Reserved	This bit is read as 0.	R
b5 to b2	FER[3:0]	Framing Error Count	Indicates the quantity of data with a framing error among the receive data stored in the receive FIFO data register (FRDR).	R
b7, b6	—	Reserved	These bits are read as 0.	R
b11 to b8	PER[3:0]	Parity Error Count	Indicates the quantity of data with a parity error among the receive data stored in the receive FIFO data register (FRDR).	R
b15 to b12	—	Reserved	These bits are read as 0.	R

Note 1. To clear the flag, 0 can be only written after 1 is read.

ORER Bit (Overrun Error Flag)

Indicates that receive operation abnormally stops due to occurrence of an overrun error. This flag is not affected and retains its previous state if the RE bit in the serial control register (SCR) is cleared to 0. The receive FIFO data register (FRDR) retains the data before an overrun error occurred, and newly received data is lost. When the ORER bit is set to 1, the SCIFA cannot continue subsequent serial reception.

[Setting condition]

- When the next serial reception is completed with the receive FIFO in full state (16-byte data is received)

[Clearing condition]

- When 0 is written to ORER after being read as 1.

Note: When the internal clock is selected while the SCIFA is in clock synchronous mode, the amount of receive data can be controlled, so no overrun occurs.

FER[3:0] Bits (Framing Error Count)

The values of bits 5 to 2 indicate the quantity of data with a framing error after the ER bit in the FSR register is set. Reading 0000 from the FER[3:0] bits means all 16-byte receive data in the FRDR register have a framing error.

PER[3:0] Bits (Parity Error Count)

The values of bits 11 to 8 indicate the quantity of data with a parity error after the ER bit in the FSR register is set. Reading 0000 from the PER[3:0] bits means all 16-byte receive data in the FRDR register have a parity error.

33.2.14 Serial Extended Mode Register (SEMR)

The SEMR register specifies either LSB or MSB first, enables the noise cancellation, operation in normal or double-speed mode of the baud rate generator, and bit rate modulation, and selects the modulation register and the sampling count (either 8 or 16 times).

Address(es): SCIFA0.SEMR A006 5014h, SCIFA1.SEMR A006 5414h, SCIFA2.SEMR A006 5814h, SCIFA3.SEMR A006 5C14h, SCIFA4.SEMR A006 6014h

	b7	b6	b5	b4	b3	b2	b1	b0
	BGDM	—	BRME	MDDRS	DIR	NFEN	—	ABCS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ABCS0	Asynchronous Base Clock Select	0: Operates on a frequency 16 times the transfer rate as the base clock. 1: Operates on a frequency 8 times the transfer rate as the base clock.	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	NFEN	Noise Cancellation Enable	0: Noise cancellation for the RxD pin is disabled. 1: Noise cancellation for the RxD pin is enabled.	R/W
b3	DIR	Data Transfer Direction Select	0: Transmits the data in the FTDR register by the LSB-first method. The received data is stored in the FRDR register by the LSB-first method. 1: Transmits the data in the FTDR register by the MSB-first method. The received data is stored in the FRDR register by the MSB-first method.	R/W
b4	MDDRS	Modulation Duty Register Select	0: BRR register is accessible. 1: MDDR register is accessible.	R/W
b5	BRME	Bit Rate Modulation Enable	0: Bit rate modulation is disabled. 1: Bit rate modulation is enabled.	R/W
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b7	BGDM	Baud Rate Generator Double-Speed Mode Select	0: Baud rate generator normal mode: Baud rate generator operates on the clock signal produced by dividing the clock source by two. 1: Baud rate generator double-speed mode: Baud rate generator operates on the clock signal produced by the clock source (no frequency division).	R/W

ABCS0 Bit (Asynchronous Base Clock Select)

Selects the base clock for 1-bit period in asynchronous mode.

This bit setting is valid only in asynchronous mode (i.e., when the CM bit in the SMR register is 0).

NFEN Bit (Noise Cancellation Enable)

Reduces noise of the input to the RxD pin. This function is only valid in asynchronous mode. For details, see section 33.7, Noise Cancellation.

In clock synchronous mode, this bit should always be set to 0.

DIR Bit (Data Transfer Direction Select)

Selects the serial communication format. This bit is valid only when the transmit/receive data is in 8-bit formats.*1

Note 1. Asynchronous mode or clock synchronous mode with the 8-bit data length

MDDRS Bit (Modulation Duty Register Select)

Selects the register to be enabled access to it.

BRME Bit (Bit Rate Modulation Enable)

Specifies whether to enable or disable the bit rate modulation.

BGDM Bit (Baud Rate Generator Double-Speed Mode Select)

Selects operating mode of the baud rate generator. When setting 1 in this bit, the baud rate generator included in the SCIFA operates in double-speed mode. The setting of this bit is only effective in asynchronous mode (SMR.CM bit = 0) when the internal clock is selected as the clock source (SCR.CKE[1:0] = 00b). Use normal mode under any other settings.

33.2.15 FIFO Trigger Control Register (FTCR)

The FTCR register is a 16-bit register that specifies FIFO trigger conditions. The CPU can always read from and write to the FTCR register.

Address(es): SCIFA0.FTCR A006 5016h, SCIFA1.FTCR A006 5416h, SCIFA2.FTCR A006 5816h, SCIFA3.FTCR A006 5C16h, SCIFA4.FTCR A006 6016h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RTRGS	—	—	RFTC[4:0]					TTRGS	—	—	TFTC[4:0]				
Value after reset:	0	0	0	1	1	1	1	1	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	TFTC[4:0]	Transmit FIFO Data Trigger Number	00h: Transmit data trigger number is 0. 0Fh: Transmit data trigger number is 15. Do not set 10h to 1Fh in these bits.	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TTRGS	Transmit Trigger Select	0: TTRG[1:0] bits in FCR are valid. 1: TFTC[4:0] bits in FTCR are valid.	R/W
b12 to b8	RFTC[4:0]	Receive FIFO Data Trigger Number	01h: Receive data trigger number is 1. 10h: Receive data trigger number is 16. Do not set 00h and 11h to 1Fh in these bits.	R/W
b14, b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	RTRGS	Receive Trigger Select	0: RTRG[1:0] bits in FCR are valid. 1: RFTC[4:0] bits in FTCR are valid.	R/W

TFTC[4:0] Bits (Transmit FIFO Data Trigger Number)

Specify the reference quantity of data for transmission (i.e., the threshold number of entries to trigger the writing of further data for transmission) for setting of the TDFE flag in the serial status register (FSR).

When the number of entries for transmission in the transmission FIFO, i.e. the number of entries written to the transmit FIFO data register (FTDR) that are yet to be transmitted, falls to or below the specified trigger number for transmission, the TDFE flag is set to 1 and a transmit FIFO data empty interrupt (TXIF) request is generated.

RFTC[4:0] Bits (Receive FIFO Data Trigger Number)

Specify the reference quantity of receive data (i.e., the threshold number of entries to trigger the reading of received data) for setting of the RDF flag in the serial status register (FSR).

When the number of entries in the reception FIFO, i.e. the number of entries yet to be read from the receive FIFO data register (FRDR), rises to or above the specified trigger number for reception, the RDF flag is set to 1 and a receive FIFO data full interrupt (RXIF) request is generated.

33.3 Operation

33.3.1 Overview

For serial communication, the SCIFA can select either asynchronous mode in which characters are synchronized individually or a clock synchronous mode in which communication is synchronized with clock pulses.
The SCIFA has a 16-stage FIFO buffer for both transmission and receptions, reducing the overhead of the CPU and enabling continuous high-speed communication. The RTS# and CTS# signals are provided as modem control signals.
Selection of a transmission/reception format is enabled with the serial mode register (SMR). Table 33.14 shows the transmission format which can be selected in the serial mode register (SMR). As shown in Table 33.15, the SCIFA clock source can be set by using the CKE[1:0] bits of the serial control register (SCR).

(1) Asynchronous Mode

- Data length is selectable either 7 or 8 bits
- Parity addition and 1- or 2-bit stop bit addition are selectable.
  (The combination of the preceding selections determines the transmission/reception format and character length).
- In reception, it is possible to detect framing errors, parity errors, receive FIFO data full, overrun errors, receive data ready, and breaks.
- The stored data quantities are indicated in the FIFO data count register (FDR), respectively for transmit and receive FIFO data.
- An internal or external clock can be selected as the SCIFA clock source.
  When an internal clock is selected, the SCIFA operates using the clock of on-chip baud rate generator and can output the clock with a frequency 16 (or 8) times the bit rate.
  When an external clock is selected, the external clock input must have a frequency 16 (or 8) times the bit rate. (The on-chip baud rate generator is not used.)

(2) Clock Synchronous Mode

- The transmission/reception format is fixed to the 8-bit data length.
- In reception, it is possible to detect overrun errors (ORER).
- An internal or external clock can be selected as the SCIFA clock source.
  When an internal clock is selected, the SCIFA operates using the clock of the on-chip baud rate generator, and outputs this clock to external devices as the synchronous clock.
  When an external clock is selected, the SCIFA operates on the input synchronous clock not using the on-chip baud rate generator.

Table 33.14 SMR Register Settings and SCIFA Communication Formats

SMR Register					SCIFA Transmission/Reception Format		
b7	b6	b5	b3				
CM	CHR	PE	STOP	Mode	Data Length	Parity Bit	Stop Bit Length
0	0	0	0	Asynchronous mode	8 bits	Not set	1 bit
			1				2 bits
		1	0			Set	1 bit
			1				2 bits
	1	0	0		7 bits	Not set	1 bit
			1				2 bits
		1	0			Set	1 bit
			1				2 bits
1	×	×	×	Clock synchronous mode	8 bits	Not set	None

×: Don't care

Table 33.15 SMR, SCR, and SPTR Register Settings and SCIFA Clock Source Selection

SMR Register	SCR Register		SPTR Register				
b7	b1	b0	b3	b2			
CM	CKE[1:0]		SCKIO	SCKDT	Mode	Clock Source	SCK Pin Function
0	0	0	0	×	Asynchronous mode	Internal	Input pin (input signal invalid) (Initial state)
			1	0			SCK pin state: Low
			1	1			SCK pin state: High
		1	×	×			Outputs a clock with frequency 16/8 times the bit rate*1
	1	0	×	×		External	Inputs a clock with frequency 16/8 times the bit rate*2
		1	×	×		Setting prohibited	
1	0	×	×	×	Clock synchronous mode	Internal	Outputs the synchronous clock
	1	0	×	×		External	Inputs the synchronous clock
		1	×	×		Setting prohibited	

×: Don't care

Note 1. SEMR.ABCS0 = 0: Output a clock that has a frequency 16 times the bit rate.
SEMR.ABCS0 = 1: Output a clock that has a frequency 8 times the bit rate.

Note 2. SEMR.ABCS0 = 0: Input a clock that has a frequency 16 times the bit rate.
SEMR.ABCS0 = 1: Input a clock that has a frequency 8 times the bit rate.

33.3.2 Operation in Asynchronous Mode

In asynchronous mode, each transmitted or received character begins with a start bit and ends with a stop bit. Serial communication is synchronized one character at a time.

The transmitting and receiving sections of the SCIFA are independent, so full duplex communication is possible. The transmitter and receiver are 16-stage FIFO buffered, so data can be written and read while transmitting and receiving are in progress, enabling continuous transmission and reception.

Figure 33.2 shows the general format of asynchronous serial communication.

In asynchronous serial communication, the communication line is normally held in the mark (high) state. The SCIFA monitors the line and starts serial communication when the line goes to the space (low) state, considered as a start bit. One serial character consists of a start bit (low), data (LSB first when LSB-first transfer is selected), parity bit (high or low), and stop bit (high), in that order.

When receiving in asynchronous mode, the SCIFA synchronizes at the falling edge of the start bit. The SCIFA samples each data bit on the eighth pulse of a clock with a frequency 16 or 8 times the bit rate*1. Receive data is latched at the center of each bit.

Note 1. When the SEMR.ABCS0 bit = 0, data is sampled on the eighth pulse of a clock with a frequency 16 times the bit rate.
When the SEMR.ABCS0 bit = 1, data is sampled on the fourth pulse of a clock with a frequency 8 times the bit rate.

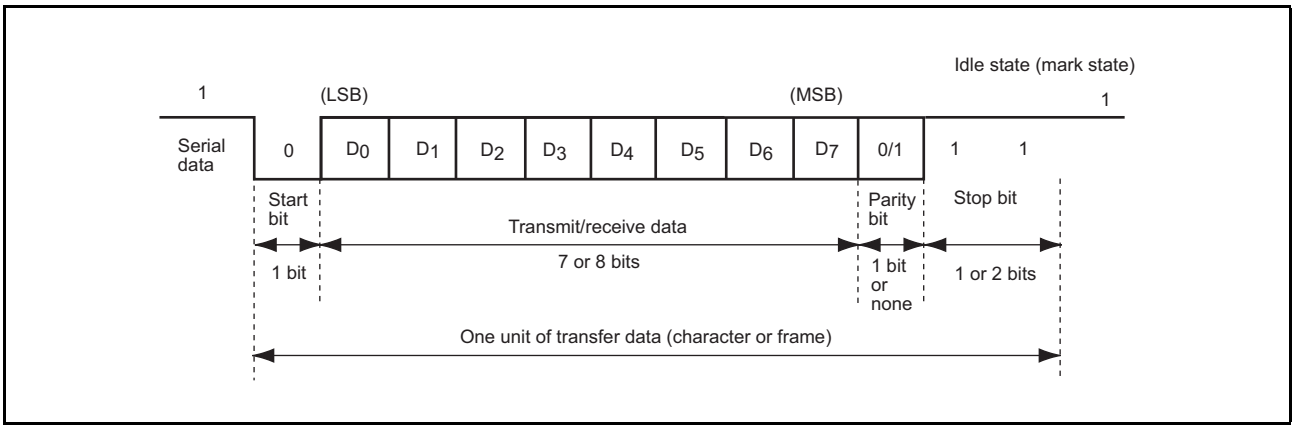


Figure 33.2 Data Format in Asynchronous Communication (8-Bit Data with Parity and Two Stop Bits when LSB-First Transfer is Selected)

(1) Transmit/Receive Formats

Table 33.16 lists the eight communications formats that can be selected in asynchronous mode. The format is selected by setting in the serial mode register (SMR).

Table 33.16 Serial Communications Formats (in Asynchronous Mode)

SMR Setting			Serial Transmit/Receive Format and Frame Length											
CHR	PE	STOP	1	2	3	4	5	6	7	8	9	10	11	12
0	0	0	START	8-bit data								STOP		
		1	START	8-bit data								STOP	STOP	
	1	0	START	8-bit data								P	STOP	
		1	START	8-bit data								P	STOP	STOP
1	0	0	START	7-bit data							STOP			
		1	START	7-bit data							STOP	STOP		
	1	0	START	7-bit data							P	STOP		
		1	START	7-bit data							P	STOP	STOP	

START: Start bit
STOP: Stop bit
P: Parity bit

(2) Clock

An SCIFA transmit/receive clock can be selected from two types of clock sources: the internal clock generated by the on-chip baud rate generator or the external clock input from the SCK pin. The clock source is selected by the settings of the CM bit in the serial mode register (SMR), the CKE[1:0] bits in the serial control register (SCR), and the ACS0 bit in the serial extended mode register (SEMR). For clock source selection, refer to Table 33.15.

When an external clock is input at the SCK pin, it must have a frequency equal to 16/8 times the desired bit rate.

When the SCIFA operates on an internal clock, it can output a clock signal on the SCK pin. The frequency of this output clock is 16/8 times the desired bit rate.

(3) Transmitting and Receiving Data

- SCIFA Initialization (in Asynchronous Mode)

Before transmitting or receiving data, clear the TE and RE bits to 0 in the serial control register (SCR), and then initialize the SCIFA as follows.

When changing operating mode or communication format, always clear the TE and RE bits in the SCR register to 0 before following the procedure given below. Clearing TE to 0 initializes the transmit shift register (TSR). Clearing TE and RE to 0, however, does not initialize the serial status register (FSR), transmit FIFO data register (FTDR), or receive FIFO data register (FRDR), which retain their previous contents. Clear TE to 0 after all transmit data has been transmitted and the TEND flag in the FSR register is set. The TE bit can be cleared to 0 during transmission, but the transmit data (the TXD pin output level) after the TE bit is cleared to 0 depends on the settings of the SPB2IO and SPB2DT bits in the SPTR register. Set the TFRST bit in the FCR register to 1 and reset the FTDR register before TE is set to 1 again to start transmission.

When an external clock is used, the clock should not be stopped during initialization or subsequent operation. SCIFA operation becomes unreliable if the clock is stopped. Figure 33.3 shows a sample flowchart for initializing the SCIFA in asynchronous mode.

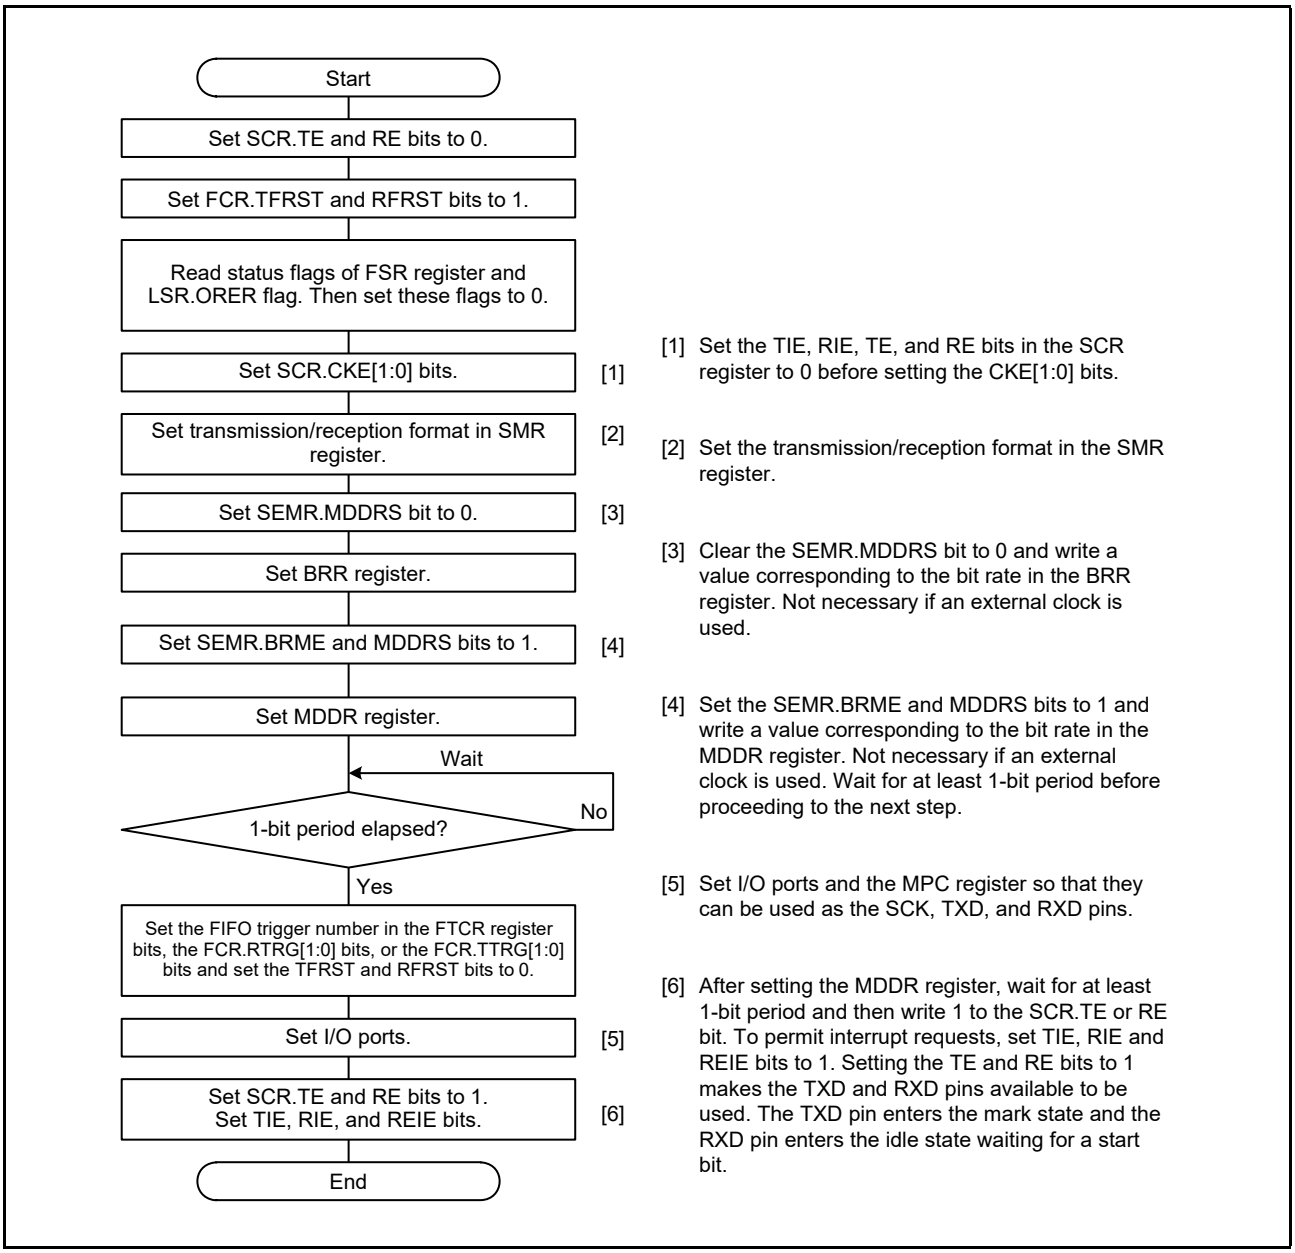

Figure 33.3 Sample Flowchart for SCIFA Initialization in Asynchronous Mode

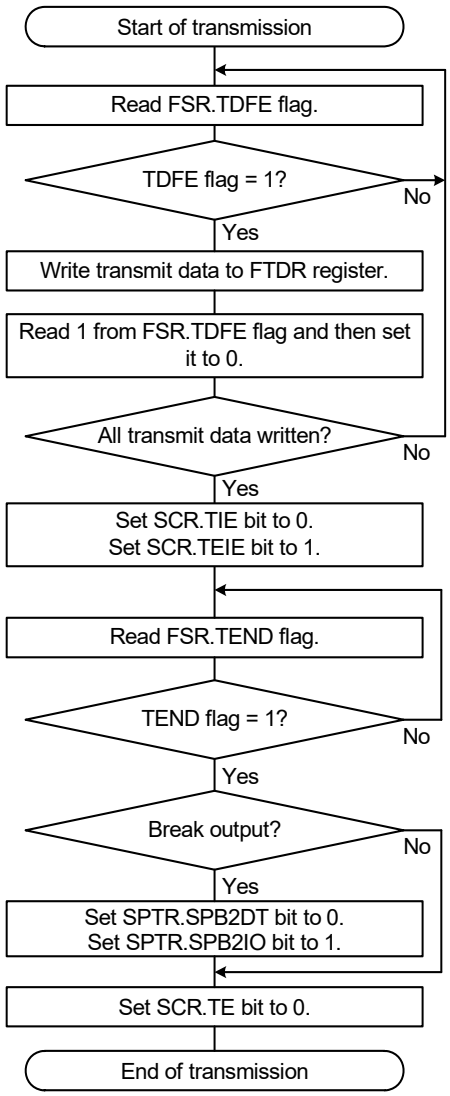
- Transmitting Serial Data (in Asynchronous Mode)

Figure 33.4 shows a sample flowchart for serial transmission in asynchronous mode.
Follow the procedure given below for serial data transmission after enabling the SCIFA for transmission.



[1] Check the SCIFA status and write the transmit data:
Read the FSR register, confirm that the TDFE flag is set to 1, and then write the transmit data to the FTDR register. The transmit data quantity that can be written is "16 - FDR.T[4:0]".
A change of the TDFE flag from 0 to 1 can be known by a TXIF interrupt request.

[2] Serial transmission continuation procedure (when the FTDR register is written by the CPU):
To continue serial transmission, confirm that the TDFE flag in the FSR register is set to 1, and then write 0 to the flag.

[3] Serial transmission end procedure (when TXIF or TEIF interrupt is used):
After the last transmission data is written to the FTDR register, set the TIE bit to 0 and the TEIE bit to 1 in the SCR register. If the DMAC is activated to write the transmit data to the FTDR register, enable the transmit end interrupt. This will generate a CPU interrupt request when the last transmit data is written in the FTDR register. The TIE and TEIE bit settings will be changed by the CPU interrupt process.
This procedure is unnecessary if the TXIF or TEIF interrupt is not used.

[4] Serial transmission end confirmation:
Read the FSR register and confirm that the TEND flag has changed to 1.
A change of the TEND flag from 0 to 1 can be known by a TEIF interrupt request.

[5] Break output during serial transmission:
To cause a break to be output during serial transmission, set the SPB2DT bit to 0 and the SPB2IO bit to 1 in the SPTR register. Then set the SCR.TE bit to 0.*1

In Step [1], the number of data bytes that can be written can be checked by the FDR.T[4:0] flag (non-transmitted data quantity in the FTDR register).

Note 1. The SPB2DT bit of the SPTR register indicates the input status of the RXD pin. Writings to the SPB2DT and SPB2IO bits of this register in 1-bit unit are handled as read-modify-write, which may lead to undesired values to be written to the SPB2DT bit. To avoid this, when modifying the SPB2DT or SPB2IO bit, for example, write the other bit (the bit used in combination) at the same time.

Figure 33.4 Sample Flowchart for Transmitting Serial Data in Asynchronous Mode

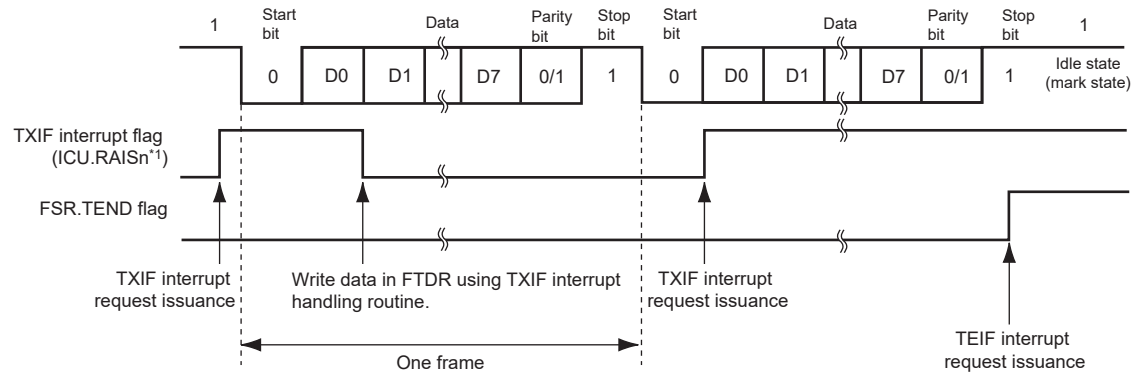
In asynchronous mode, the SCIFA performs serial transmission as described below.

1. When data is written into the transmit FIFO data register (FTDR) by the TXIF interrupt processing routine, the SCIFA transfers the data from the FTDR register to the transmit shift register (TSR) and starts transmission. Confirm that the TDFE flag in the serial status register (FSR) is set to 1 before writing transmit data to the FTDR register. The number of data bytes that can be written is “16 minus the number of non-transmitted data units”.
2. When data is transferred from the FTDR register to the TSR register and transmission is started, consecutive transmit operations are performed until there is no transmit data left in the FTDR register. When the number of transmit data bytes in the FTDR register becomes equal to or less than the transmission trigger number specified in the FIFO control register (FCR) or FIFO trigger control register (FTCR), the TDFE flag is set. If the TIE bit in the serial control register (SCR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXIF) request is generated.

   The serial transmit data is output from the TXD pin in the following order.

   (a) Start bit: One-bit 0 is output.
   (b) Transmit data: 8- or 7-bit data is output in LSB-first order (when LSB-first transfer is selected).
   (c) Parity bit: One parity bit (even or odd parity) is output. (A format in which a parity bit is not output can also be selected.)
   (d) Stop bit(s): One or two 1 bits (stop bits) are output.
   (e) Mark state: 1 is output continuously until the start bit that starts the next transmission is output.
3. The SCIFA checks the transmit data of the FTDR register at the timing for sending the stop bit. If data is present, the data is transferred from the FTDR register to the TSR register, the stop bit is output, and then serial transmission of the next frame is started. If there is no data to be transmitted, the TEND flag in the FSR register is set to 1, the stop bit is output, and then the SCIFA enters the mark state (high level) in which 1 is output continuously.

Figure 33.5 shows an example of the operation for transmission in asynchronous mode.



Note 1. For the corresponding interrupt number, see section 12, Interrupt Controller (ICUA).

Figure 33.5 Example of Transmit Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected)

4. When modem control is enabled, transmission can be stopped/resumed by the input level to the CTS# pin. When a high level is input to the CTS# pin during transmission, the SCIFA enters the mark state (high level) after completion of one-frame data transmission. When a low level is input to the CTS# pin, output of the next data to be transmitted begins with a start bit. Figure 33.6 shows an example of the operation for transmission when using the modem control function.

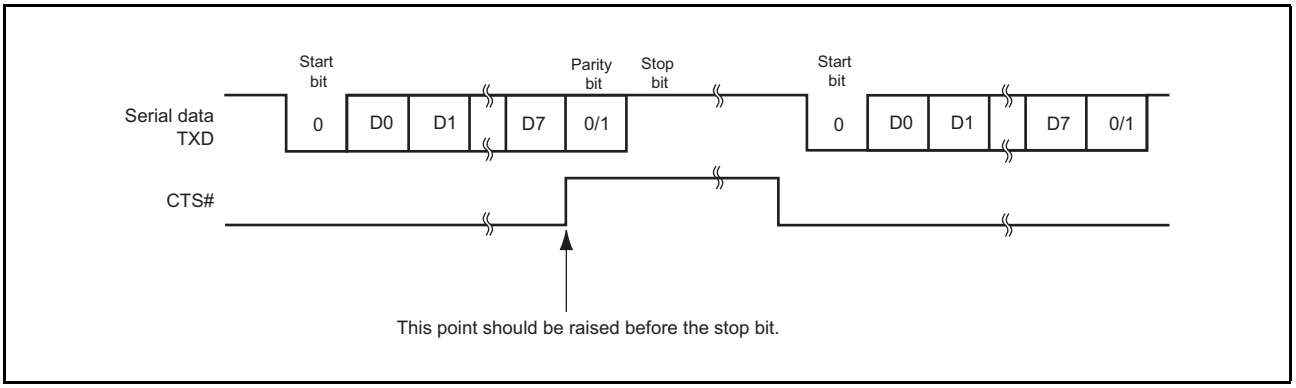


Figure 33.6 Example of Transmit Operation in Asynchronous Mode Using Modem Control Function (CTS#)

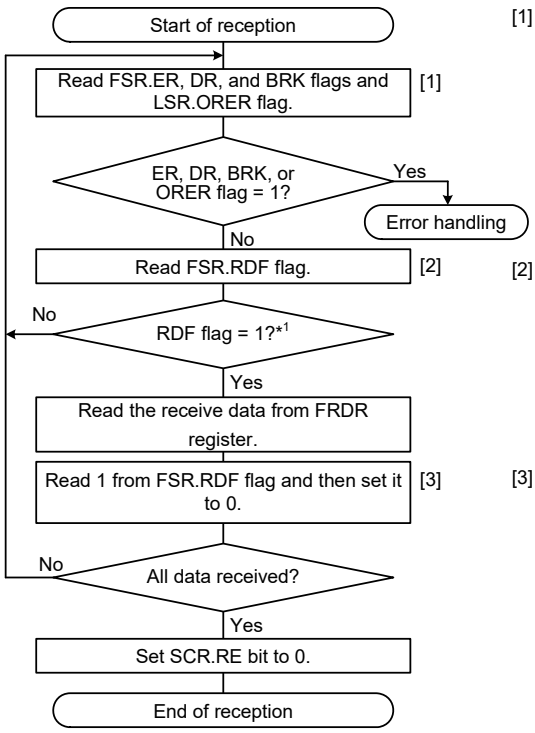
- Receiving Serial Data (in Asynchronous Mode)

Figure 33.7 and Figure 33.8 show sample flowcharts for serial reception in asynchronous mode.
Follow the procedure given below for serial data reception after enabling the SCIFA for reception.



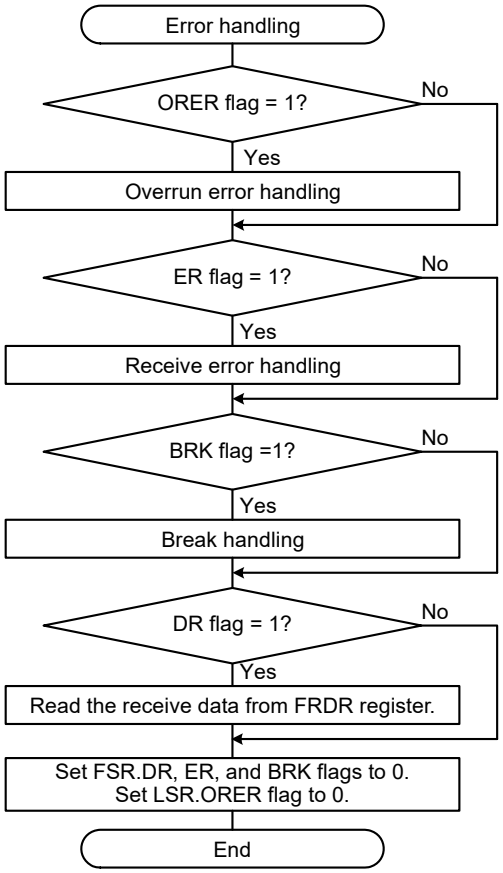
[1] Receive error handling and break detection:
When a receive error occurs, read the ER, DR, and BRK flags in the FSR register and the LSR.ORER flag to identify the error. After handling the error as specified, clear the ER, DR, BRK, and ORER flags to 0.
In the case where a framing error occurs, a break can be detected by reading the value of the RXD pin.
Error occurrence can be known by a BRIF, ERIF, or DRIF interrupt request.

[2] Check the SCIFA status and read the receive data:
Read the FSR register, confirm that the RDF flag is set to 1, and then read the receive data at least as much as the amount specified as the receive data trigger number from those stored in the FRDR register. The receive data quantity that can be read can be checked by the FDR.R[4:0] flag.
A change of the RDF flag from 0 to 1 can be known by an RXIF interrupt request.

[3] Serial reception continuation procedure (when the FRDR register is read by the CPU):
To continue serial reception, confirm that the RDF flag in the FSR register is set to 1, and then write 0 to the flag.

Note 1. The number of all the received data units should be an integral multiple of the receive data trigger number. If not, process returns to Step [1] and enters an infinite loop. In this case, it is necessary to set the timeout processing using a timer.

Figure 33.7 Sample Flowchart for Receiving Serial Data in Asynchronous Mode (1)



- Whether a framing error or parity error has occurred in the received data that is read from the FRDR register can be checked with the FER and PER flags in the FSR register.
- When a break signal is received, the received data is not transferred to the FRDR register while the BRK flag is set to 1. However, note that the last data in the FRDR register is 00h and the break data in which a framing error occurred is stored.

Figure 33.8 Sample Flowchart for Receiving Serial Data in Asynchronous Mode (2)

In asynchronous mode, the SCIFA performs serial reception as described below.

1. The SCIFA monitors the communication line, and if a 0 start bit is detected, it performs internal synchronization to start reception.
2. The received data is stored into the RSR register in LSB-to-MSB order (when LSB-first transfer is selected).
3. The parity bit and stop bit are received.
   After receiving these bits, the SCIFA carries out the following checks.
   (a) Stop bit check: The SCIFA checks whether the stop bit is 1. If there are two stop bits, only the first is checked.
   (b) The SCIFA checks whether receive data can be transferred from the receive shift register (RSR) to the receive FIFO data register (FRDR).
   (c) Parity bit check: The SCIFA checks whether the parity bit is an expected value.
   (d) Overrun error check: The SCIFA checks whether the ORER flag is 0, indicating that the overrun error has not occurred.
   (e) Break check: The SCIFA checks whether the BRK flag is 0, indicating that the break state is not set.

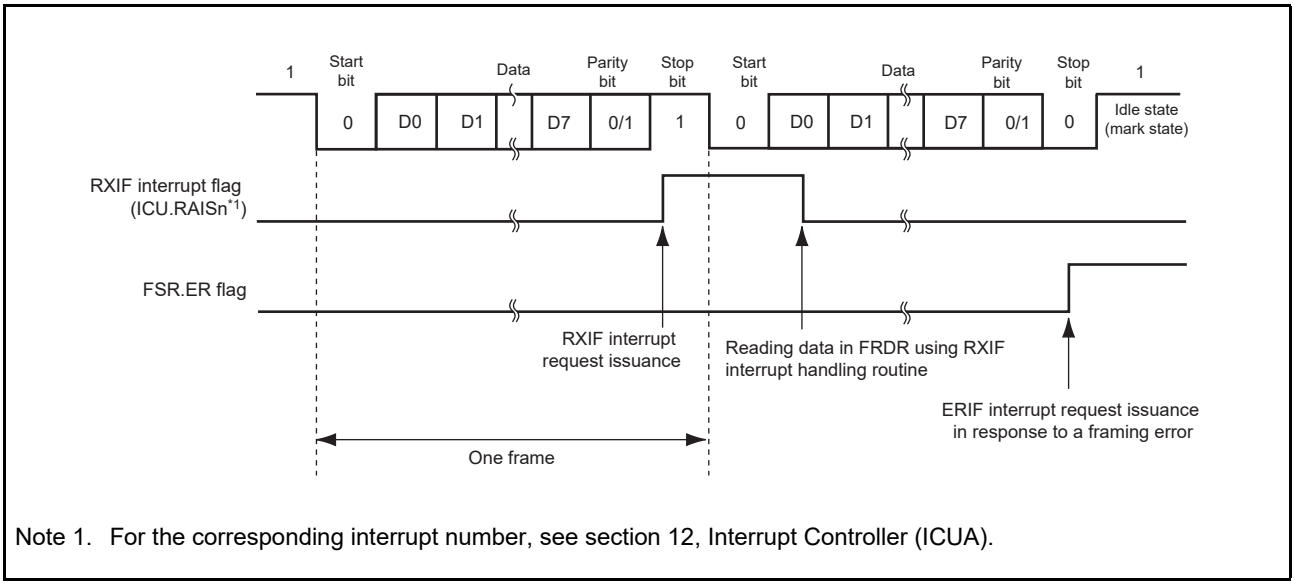
If all the above checks are passed, the receive data is stored in the FRDR register.

Note: When a parity error or a framing error occurs, reception is not suspended.

4. When receive data units equaling or exceeding the specified reception trigger number are stored in the receive FIFO data register (FRDR) and the RDF flag is changed to 1, a receive FIFO data full interrupt (RXIF) request is generated while the RIE bit in the SCR register is set to 1. When the quantity of data in the FRDR register falls below the specified reception trigger number and the RIE bit in the SCR register is set to 1, a receive data ready interrupt (DRIF) request is generated if no next data is received after the elapse of 15 ETUs*1 from the last stop bit (the DR flag in the FSR register is 1). When the ER flag in the FSR register is changed to 1, a receive error interrupt (ERIF) request is generated while the RIE or REIE bit in the SCR register is set to 1. When the BRK or ORER flag is changed to 1 in the FSR register, a break reception interrupt (BRIF) request is generated while the RIE or REIE bit in the SCR register is set to 1.

Note 1. It is equivalent to 1 and half frames of 8-bit format with one stop bit (ETU: Element Time Unit).

Figure 33.9 shows an example of the operation for reception in asynchronous mode.



Note 1. For the corresponding interrupt number, see section 12, Interrupt Controller (ICUA).

Figure 33.9 Example of SCIFA Receive Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected)

5. When modem control is enabled, the RTS# signal that indicates the FRDR register has space is output. When the RTS# pin is at low level, reception is possible. The RTS# pin being at the high level indicates that the number of entries in the FRDR register is equal to or greater than the threshold for output of the active level of the RTS# signal and that the transmission of further data needs to be suspended until the FRDR register has enough space. Figure 33.10 shows an example of the operation for reception in asynchronous mode when using the modem control function.

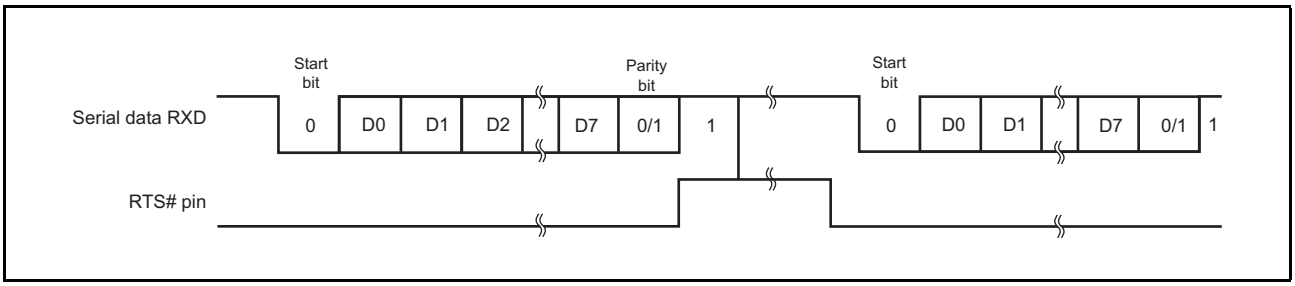


Figure 33.10 Example of SCIFA Receive Operation in Asynchronous Mode Using Modem Control Function (RTS#)

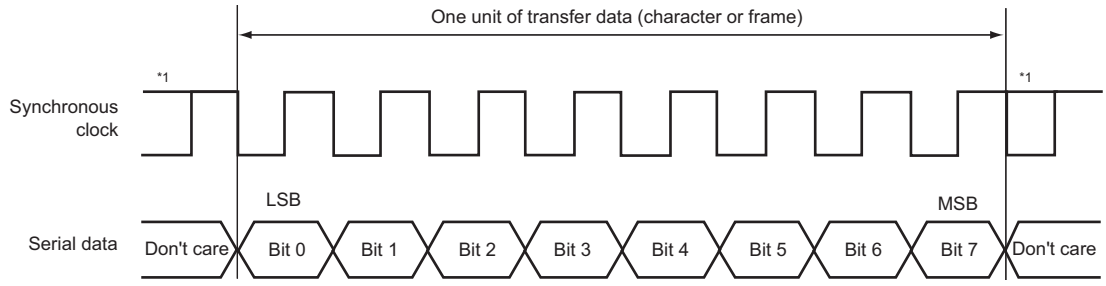
33.3.3 Operation in Clock Synchronous Mode

In clock synchronous mode, the SCIFA transmits and receives data in synchronization with clock pulses. This mode is suitable for high-speed serial communication.
Full-duplex communication is possible because the SCIFA transmitter and receiver are independent and share the same clock. Since the transmitter and the receiver have 16-stage FIFO buffers, respectively, continuous transmission or reception is possible by reading or writing data while transmission or reception is in progress.
Figure 33.11 shows the general format in clock synchronous serial communication.



Note 1. High level except in continuous transmission/reception

Figure 33.11 Data Format in Clock Synchronous Communication (when LSB-First Transfer is Selected)

In clock synchronous serial communication, each data bit is output on the communication line from one falling edge of the synchronous clock to the next. Data is guaranteed valid at the rising edge of the synchronous clock.
In each character, the serial data bits are transmitted in order from the LSB (first) to the MSB (last). After output of the MSB, the communication line remains in the state of the MSB (when LSB-first transfer is selected).
In clock synchronous mode, the SCIFA receives data by synchronizing with the rising edge of the synchronous clock.

(1) Transmit/Receive Formats

The data length is fixed at eight bits.
No parity bit can be added.

(2) Clock

An internal clock generated by the on-chip baud rate generator or an external clock input from the SCK pin can be selected as the SCIFA transmit/receive clock according to the settings of the CM bit in the serial mode register (SMR), the CKE[1:0] bits in the serial control register (SCR), and the ACS0 bit in the serial extended mode register (SEMR).
When the SCIFA operates on an internal clock, it outputs the synchronous clock signal at the SCK pin. Eight synchronous clock pulses are output per transmitted or received character. Unless the SCIFA is transmitting or receiving, the synchronous clock signal remains in the high state. When the SCIFA only receives data on an internal clock, the internal clock signal outputs while the RE bit in the SCR register is 1 until the number of data units in the receive FIFO reaches the specified reception trigger number.

(3) Transmitting and Receiving Data

- SCIFA Initialization (in Clock Synchronous Mode)

Before transmitting or receiving, clear the TE and RE bits to 0 in the serial control register (SCR), and then initialize the SCIFA by performing the following procedure.
Similarly, before changing the mode or communication format, clear the TE and RE bits to 0, and then change it by performing the following procedure. Clearing TE to 0 initializes the transmit shift register (TSR). Clearing RE to 0, however, does not initialize the RDF, PER, FER, and ORER flags and the receive FIFO data register (FRDR), which retain their previous contents.

Figure 33.12 shows a sample flowchart for initializing the SCIFA in clock synchronous mode.

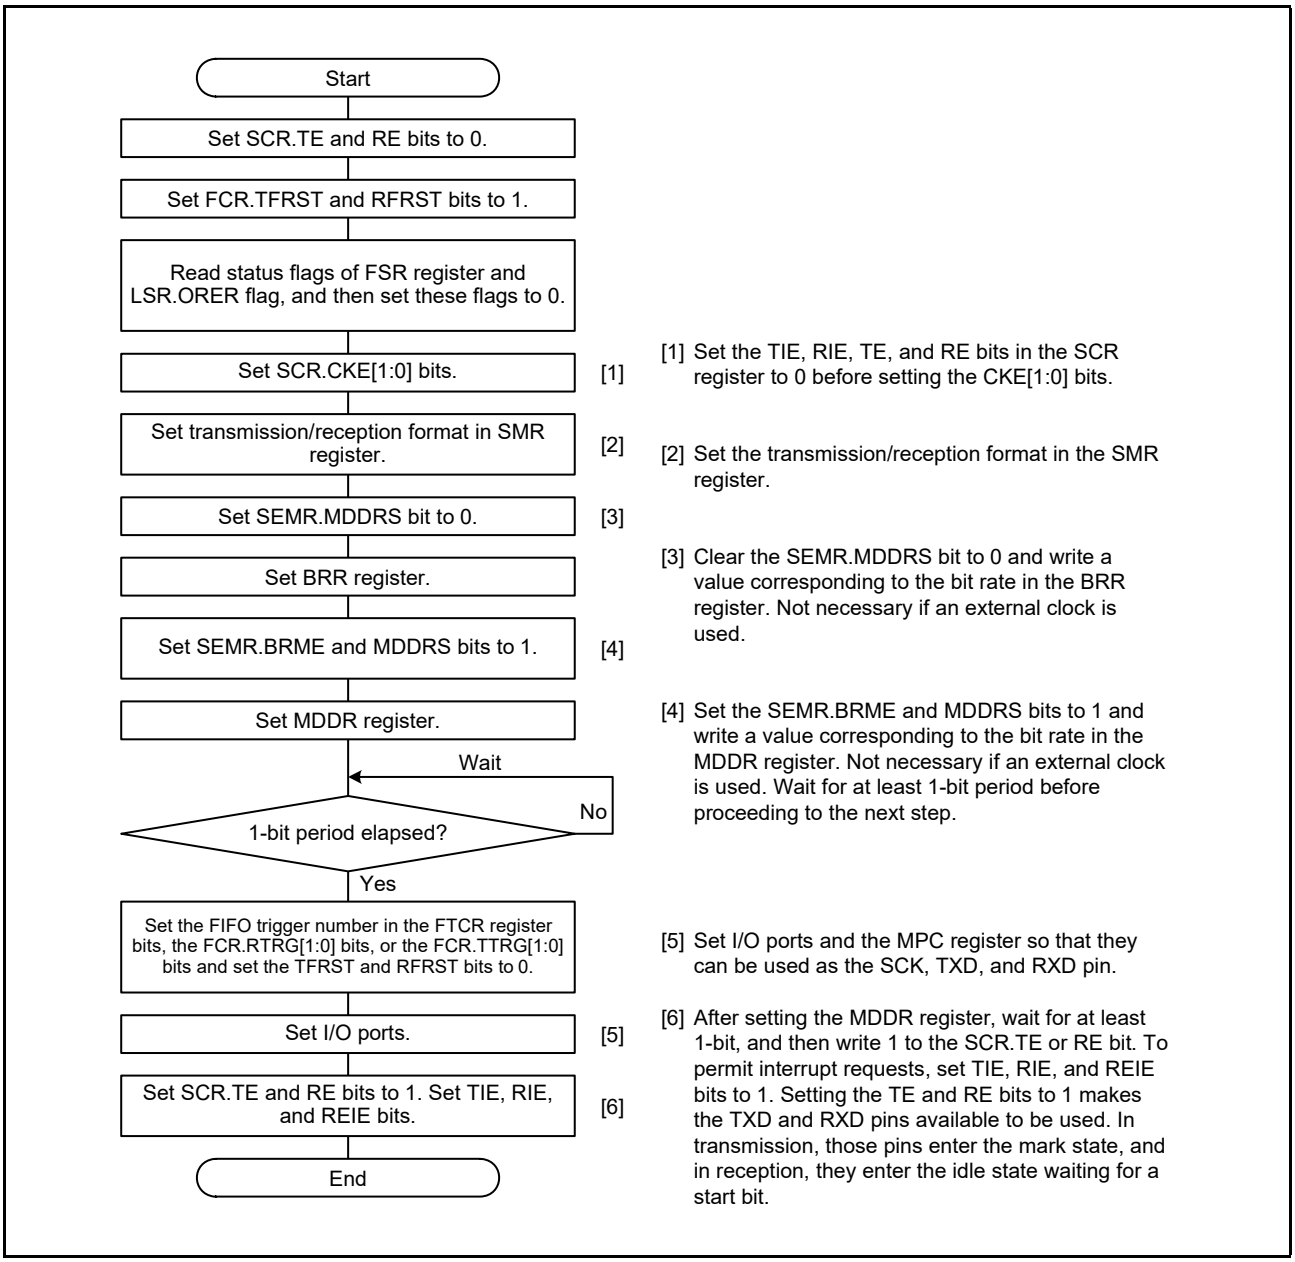


Figure 33.12 Sample Flowchart for SCIFA Initialization in Clock Synchronous Mode

- Transmitting Serial Data (in Clock Synchronous Mode)

Figure 33.13 shows a sample flowchart for transmitting serial data in clock synchronous mode.
Follow the procedure given below for serial data transmission after enabling the SCIFA for transmission.

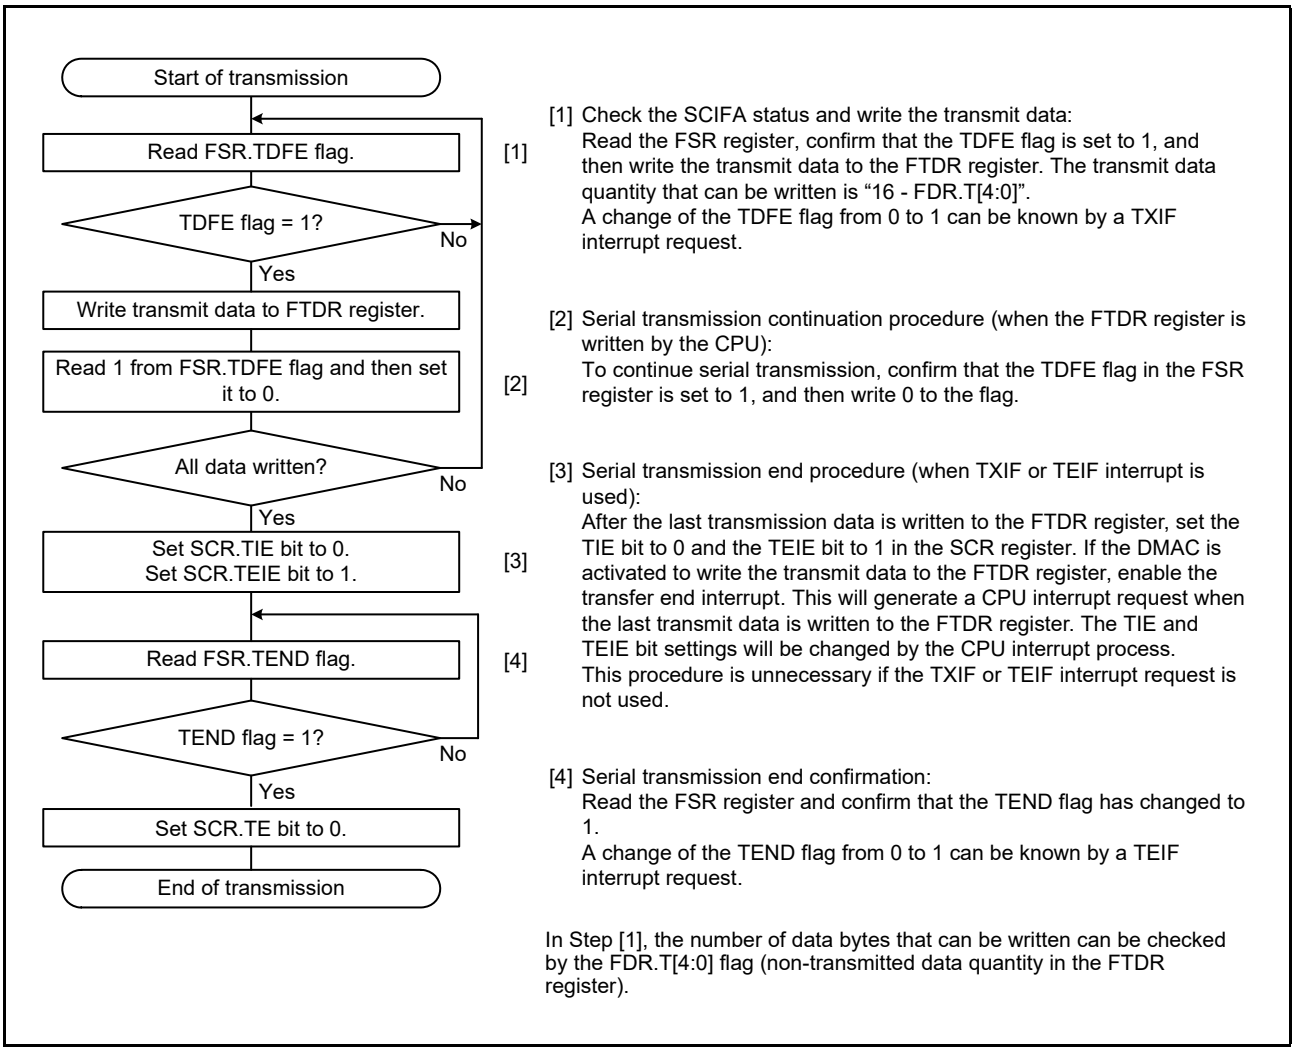

Figure 33.13 Sample Flowchart for Transmitting Serial Data in Clock Synchronous Mode

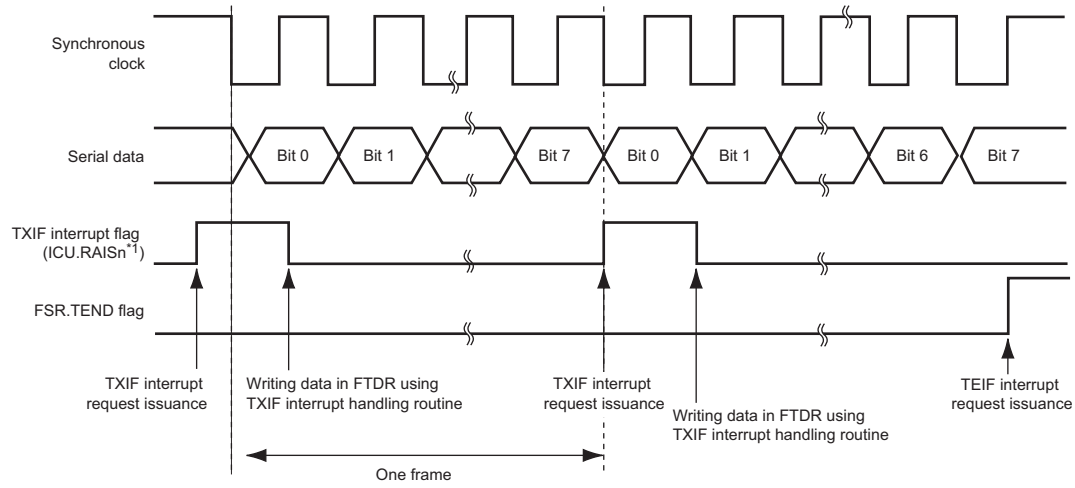
In clock synchronous mode, the SCIFA performs serial transmission as described below.

1. When data is written into the transmit FIFO data register (FTDR) by the TXIF interrupt processing routine, the SCIFA transfers the data from the FTDR register to the transmit shift register (TSR) and starts transmission. Confirm that the TDFE flag in the serial status register (FSR) is set to 1 before writing transmit data to the FTDR register. The number of data bytes that can be written is “16 minus the specified number of non-transmitted data units”.
2. When data is transferred from the FTDR register to the TSR register and transmission is started, consecutive transmit operations are performed until there is no transmit data left in the FTDR register. When the number of transmit data bytes in the FTDR register becomes equal to or less than the transmission trigger number set in the FIFO control register (FCR) or FIFO trigger control register (FTCR), the TDFE flag in the FSR register is set. If the TIE bit in the serial control register (SCR) is set to 1 at this time, a transmit-FIFO-data-empty interrupt (TXIF) request is generated.
   If clock output mode is selected, the SCIFA outputs eight synchronous clock pulses. If an external clock source is selected, the SCIFA outputs data in synchronization with the input clock. Data is output from the TXD pin in order from the LSB (b0) to the MSB (b7) (when LSB-first transfer is selected).
3. The SCIFA checks the transmit data of the FTDR register at the timing for sending the MSB (bit 7). If data is present, the data is transferred from the FTDR register to the TSR register, and then serial transmission of the next frame is started. If there is no data, the TXD pin holds the output level of the last data after the TEND flag in the FSR register is set to 1 and the MSB (bit 7) is output.
4. After the end of serial transmission, the SCK pin is held in the high state.

Figure 33.14 shows an example of SCIFA transmit operation in clock synchronous mode.

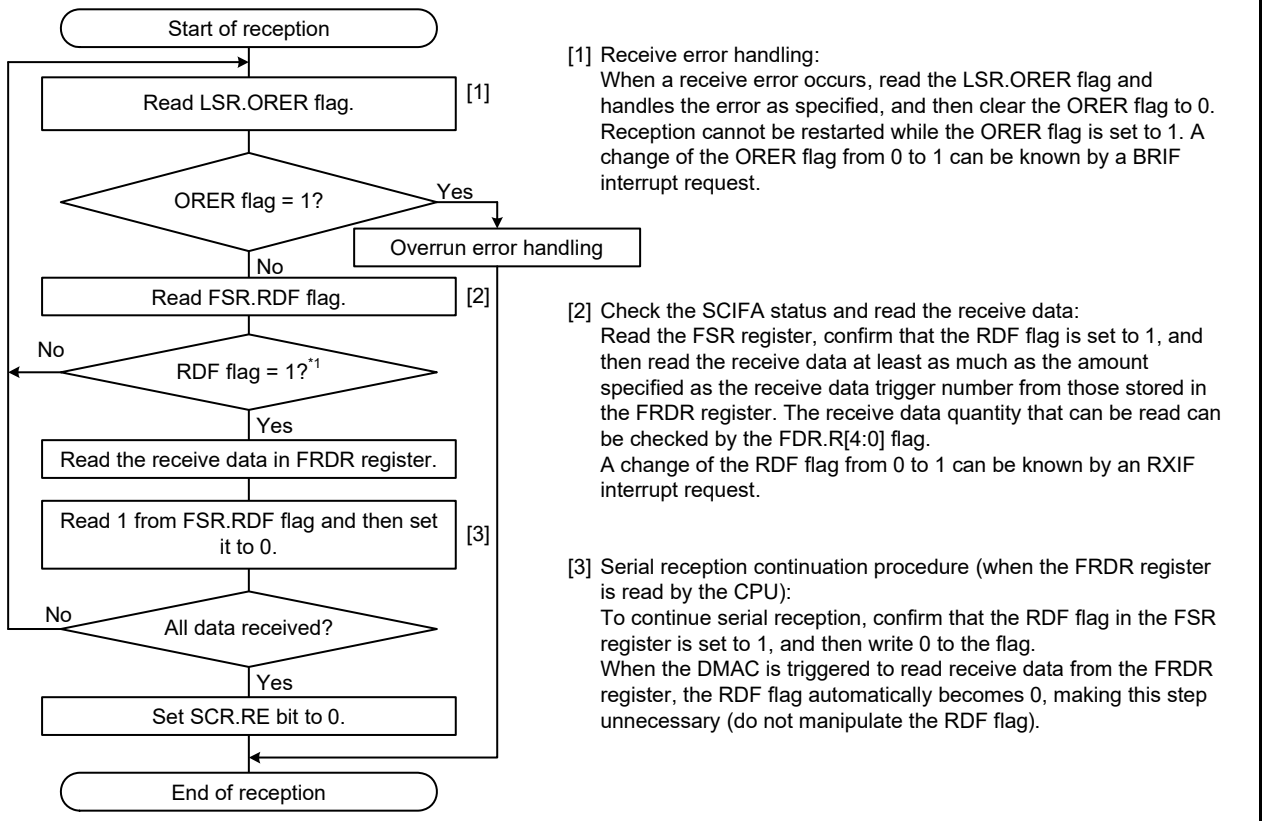


Note 1. For the corresponding interrupt number, see section 12, Interrupt Controller (ICUA).

Figure 33.14 Example of SCIFA Transmit Operation in Clock Synchronous Mode (when LSB-First Transfer is Selected)

- Receiving Serial Data (in Clock Synchronous Mode)

Figure 33.15 shows sample flowcharts for receiving serial data in clock synchronous mode.
Follow the procedure given below for serial data reception after enabling the SCIFA for reception. When switching from asynchronous mode to clock synchronous mode without SCIFA initialization, make sure that the ORER, PER, and FER flags in the line status register (LSR) are cleared to 0.



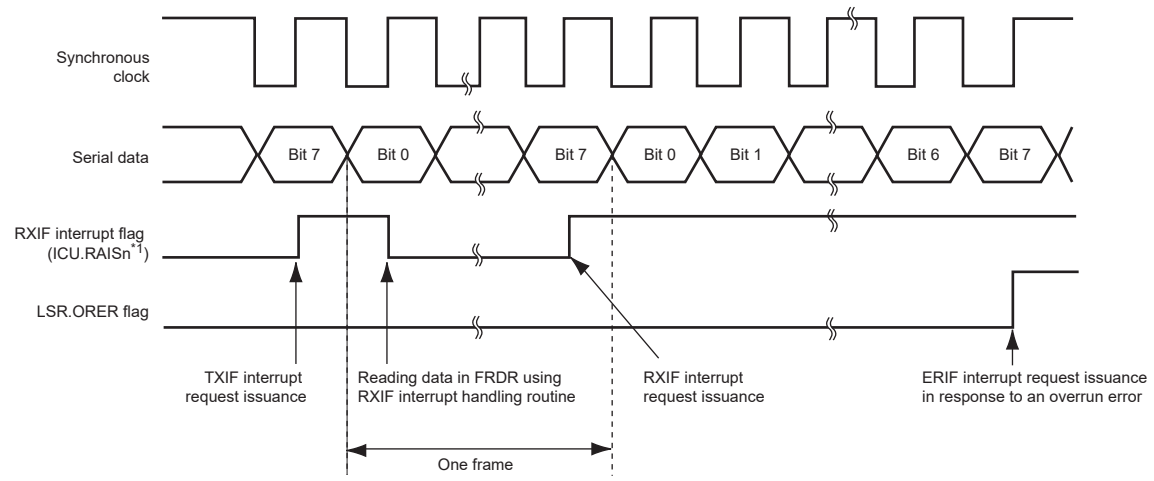
Note 1. The number of all the received data units should be an integral multiple of the receive data trigger number. If not, process returns to Step [1] and enters an infinite loop. In this case, it is necessary to set the timeout processing using a timer.

Figure 33.15 Sample Flowchart for Receiving Serial Data in Clock Synchronous Mode

In clock synchronous mode, the SCIFA performs serial reception as described below.

1. The SCIFA synchronizes with the synchronous clock input or output and starts reception.
2. Receive data is stored into the receive shift register (RSR) in order from the LSB to the MSB (when LSB-first transfer is selected). After receiving the data, the SCIFA checks whether the receive data can be transferred from the RSR register to the FRDR register. If data can be transferred, the SCIFA stores the received data in the FRDR register. If an overrun error is detected during the error check, further reception is not performed.
3. After the received data units equaling or exceeding the specified reception trigger number are stored in the FRDR register and the RDF flag is set to 1, a receive-data-full interrupt (RXIF) request is generated when the RIE bit in the serial control register (SCR) is set to 1. When the ORER flag in the line status register (LSR) is set to 1 and the RIE or REIE bit in the SCR register is also set to 1, a break interrupt (BRIF) request is generated.

Figure 33.16 shows an example of SCIFA receive operation in clock synchronous mode.



Note 1. For the corresponding interrupt number, see section 12, Interrupt Controller (ICUA).

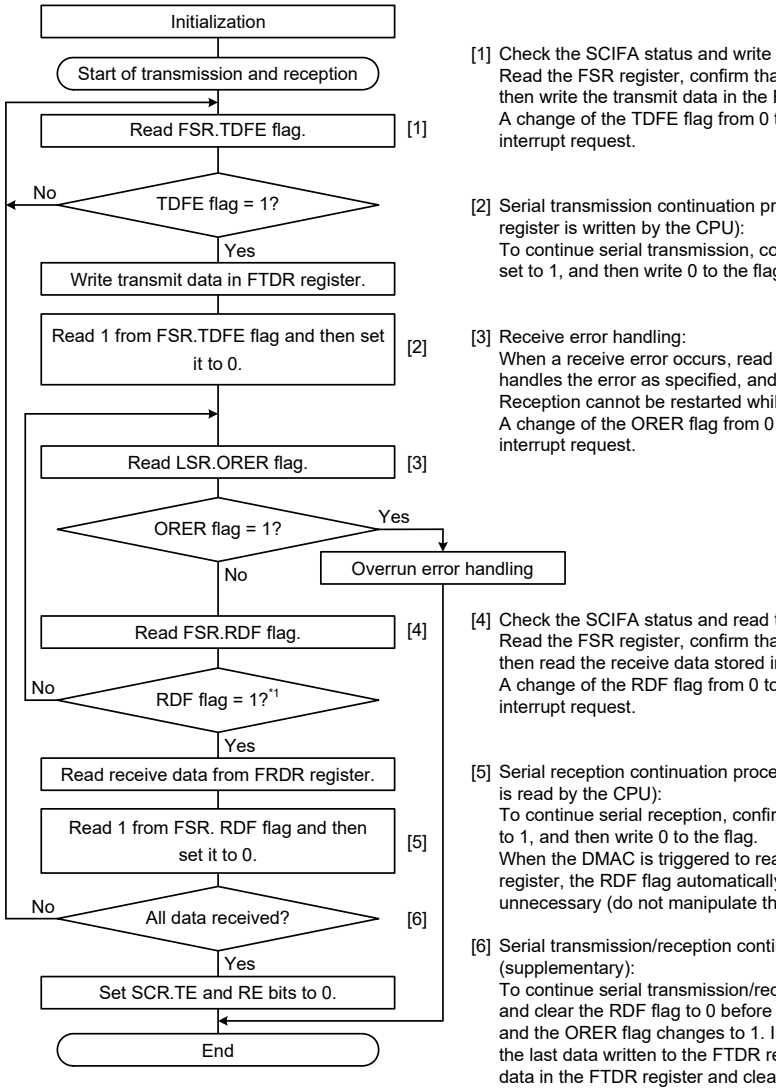
Figure 33.16 Example of SCIFA Receive Operation (when LSB-First Transfer is Selected)

- Transmitting and Receiving Serial Data Simultaneously (in Clock Synchronous Mode)

Figure 33.17 shows a sample flowchart for transmitting and receiving serial data simultaneously in clock synchronous mode.

In simultaneous transmission/reception of serial data, number of receive data = number of transmit data = number of transmit data to be written to the FTDR register.

Follow the procedure given below for the simultaneous transmission/reception of serial data, after enabling the SCIFA for transmission/reception.



[1] Check the SCIFA status and write the transmit data:
Read the FSR register, confirm that the TDFE flag is set to 1, and then write the transmit data in the FTDR register.
A change of the TDFE flag from 0 to 1 can be known by a TXIF interrupt request.

[2] Serial transmission continuation procedure (when the FTDR register is written by the CPU):
To continue serial transmission, confirm that the FSR.TDFE flag is set to 1, and then write 0 to the flag.

[3] Receive error handling:
When a receive error occurs, read the LSR.ORER flag and handles the error as specified, and then clear the ORER flag to 0.
Reception cannot be restarted while the ORER flag is set to 1.
A change of the ORER flag from 0 to 1 can be known by a BRIF interrupt request.

[4] Check the SCIFA status and read the receive data:
Read the FSR register, confirm that the RDF flag is set to 1, and then read the receive data stored in the FRDR register.
A change of the RDF flag from 0 to 1 can be known by an RXIF interrupt request.

[5] Serial reception continuation procedure (when the FRDR register is read by the CPU):
To continue serial reception, confirm that the FSR.RDF flag is set to 1, and then write 0 to the flag.
When the DMAC is triggered to read receive data from the FRDR register, the RDF flag automatically becomes 0, making this step unnecessary (do not manipulate the RDF flag).

[6] Serial transmission/reception continuation procedure (supplementary):
To continue serial transmission/reception, read the FRDR register and clear the RDF flag to 0 before the FRDR register overflows and the ORER flag changes to 1. In addition, before the last bit of the last data written to the FTDR register is transmitted, write the data in the FTDR register and clear the TDFE flag to 0.
When the DMAC is triggered to write data to the FTDR register or read data from the FRDR register, the TDFE and RDF flags automatically become 0, making this step unnecessary (do not manipulate the TDFE or RDF flag).

Note: When switching the operation from transmission or reception to the simultaneous transmission and reception, clear the TE and RE bits to 0 and then simultaneously set these bits to 1.

Note 1. The number of all the received data units should be an integral multiple of the receive data trigger number. If not, process returns to Step [1] and enters an infinite loop. In this case, it is necessary to set the timeout processing using a timer.

Figure 33.17 Sample Flowchart for Simultaneous Transmitting/Receiving Serial Data in Clock Synchronous Mode

33.4 Bit Modulation

Using the bit rate modulation, the bit rate can be corrected by skipping the specified number of clock pulses input to the baud rate generator. To correct the bit rate, only the number of clock pulses specified in the MDDR register are enabled among 256 internal clock pulses specified by the CKS[1:0] bits in the SMR register in a way that forms average intervals.

Figure 33.18 shows an example where SERICLK is selected by the CKS[1:0] bits in SMR and BRR and MDDR are set to 0 and 160, respectively, in asynchronous mode. In this example, the cycle of the base clock is evenly corrected (256/160) and the bit rate is also corrected (160/256). Note that skipping an internal clock causes bias and expansion or contraction is generated in the pulse width of the base clock.

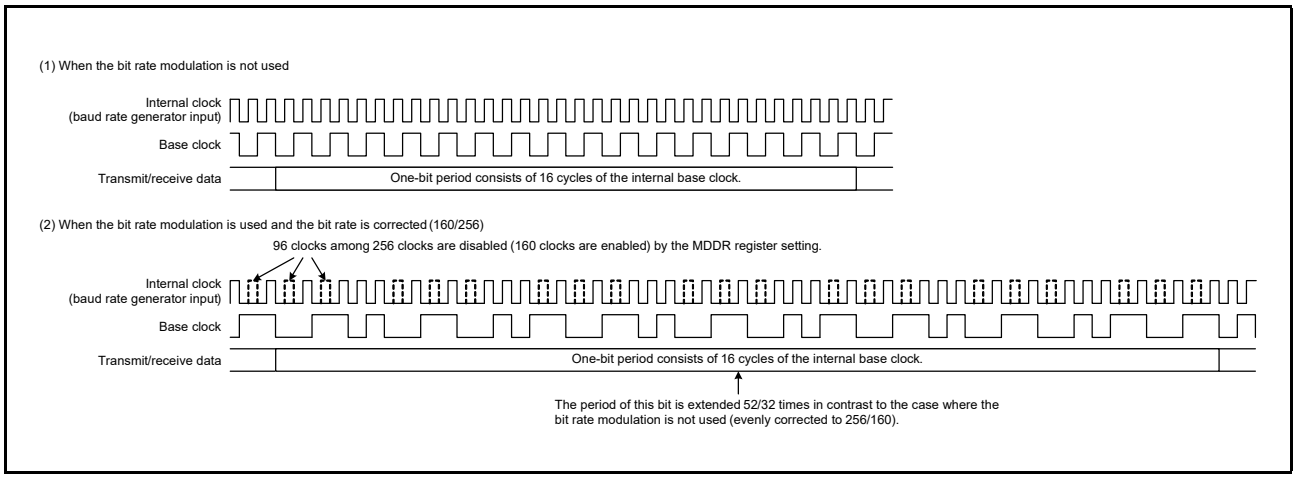


Figure 33.18 Example of Internal Base Clock when Bit Modulation is Used

33.5 Interrupt Sources

The SCIFA has six interrupt sources: transmit-FIFO-data-empty (TXIF), receive-error (ERIF), receive-FIFO-data-full (RXIF), break (BRIF), transmit-end (TEIF), receive-data-ready (DRIF). The TEIF and DRIF interrupts, the ERIF and BRIF interrupts share the same vector numbers, respectively.

Table 33.17 shows the interrupt sources and priority. The interrupt sources can be enabled or disabled using the TIE, RIE, REIE, TEIE bits in the SCR register and are separately input to the interrupt controller.

When the quantity of transmit data written in the FTDR register as a result of transmission is equal to or less than the specified transmission trigger number, the TDFE flag in the serial status register (FSR) is set to 1 and a TXIF interrupt request is generated.

When the data units equaling or exceeding the specified transmission trigger number are stored in the receive FIFO register (FRDR) and the RDF flag in the FSR register is set to 1, a receive data full interrupt (RXIF) request is generated.

When the quantity of received data in the FRDR register is below the specified reception trigger number and no next data has been received yet even after the period of 15 ETUs elapsed*1 from the last stop bit, the DR flag in the FSR register is set to 1 and a receive data ready interrupt (DRIF) request is generated. In clock synchronous mode, a DRIF interrupt request is not generated.

When the BRK flag in the FSR register or the ORER flag in the LSR register is set to 1, a BRIF interrupt request is issued.

When the ER flag in the FSR register is set to 1, an ERIF interrupt request is issued.

When the TEND flag in the FSR register is set to 1, a TEIF interrupt request is issued.

When the RIE bit is cleared to 0 and the REIE bit in the SCR register is set to 1, an ERIF and BRIF interrupt requests are issued but an RXIF and a DRIF interrupt requests are not.

An TXIF interrupt indicates that transmit data can be written and an RXIF interrupt indicates that receive data is stored in the FRDR register.

Note 1. It is equivalent to 1 and half frames of 8-bit format with one stop bit (ETU: Element Time Unit).

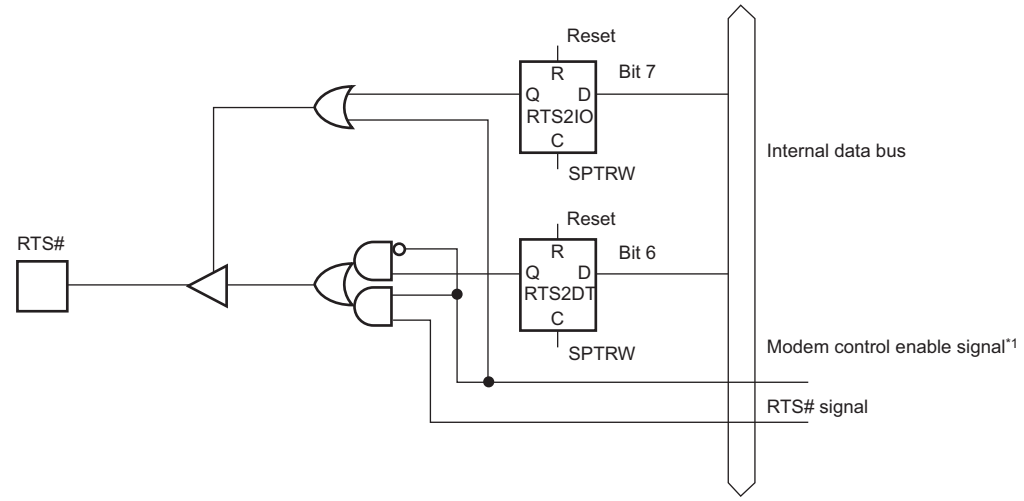
Table 33.17 SCIFA Interrupt Sources

Name	Level/ Edge	Interrupt Source	Interrupt Enable Bit	DMAC Activation	Priority
BRIF	Level	Interrupt caused by break (BRK) or overrun (ORER).	RIE or REIE	Impossible	High
ERIF	Level	Interrupt caused by framing or parity (ER).	RIE or REIE	Impossible	
RXIF	Level	Interrupt caused by receive FIFO data full (RDF).	RIE	Possible	
TXIF	Level	Interrupt caused by transmit FIFO data empty (TDFE).	TIE	Possible	
TEIF	Level	Interrupt caused by transmit end (TEND).	TEIE	Impossible	
DRIF	Level	Interrupt caused by receive data ready (DR).	RIE	Impossible	Low

Note: The TEIF and DRIF interrupts share the same vector number.

33.6 Serial Port Register (SPTR) and SCIFA-Related Pins

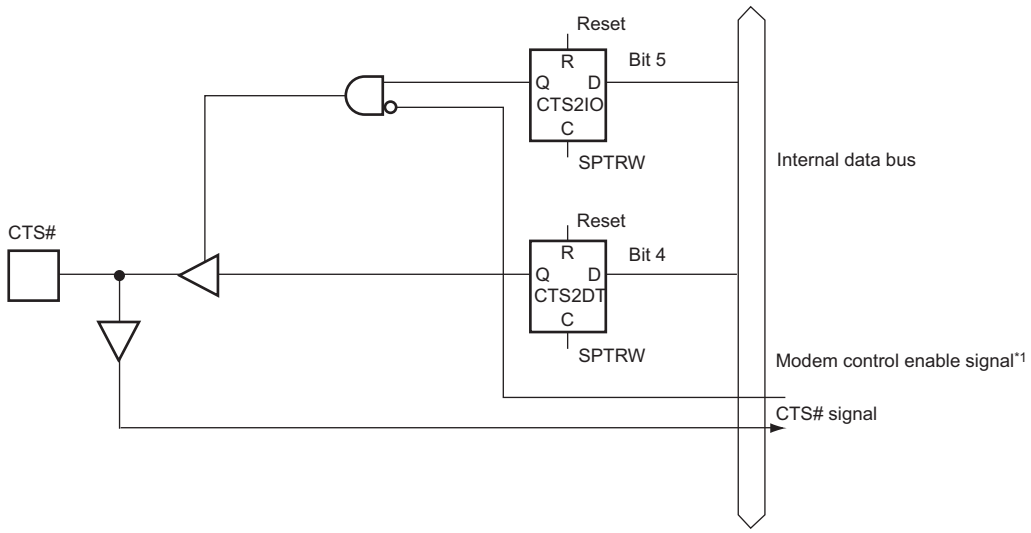
Figure 33.19 to Figure 33.22 show the relationships between the SPTR register and the SCIFA-related pins.



SPTRW: SPTR write

Note 1. These signals allow the RTS# pin to enter the modem control state with the MCE bits in FCR.

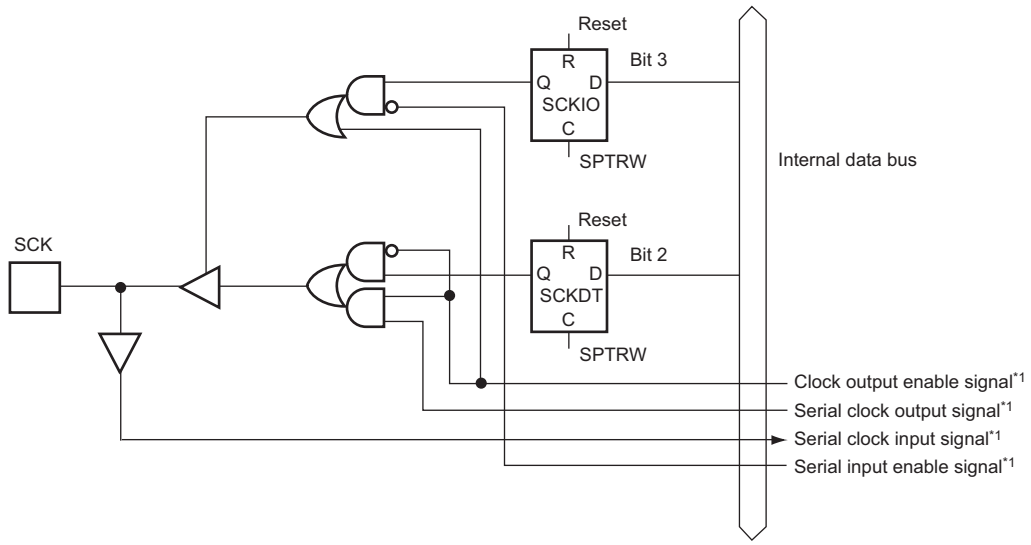
Figure 33.19 RTS2IO Bit and RTS2DT Bit in the SPTR Register, and RTS# Pin



SPTRW: SPTR write

Note 1. These signals allow the CTS# pin to enter the modem control state with the MCE bits in FCR.

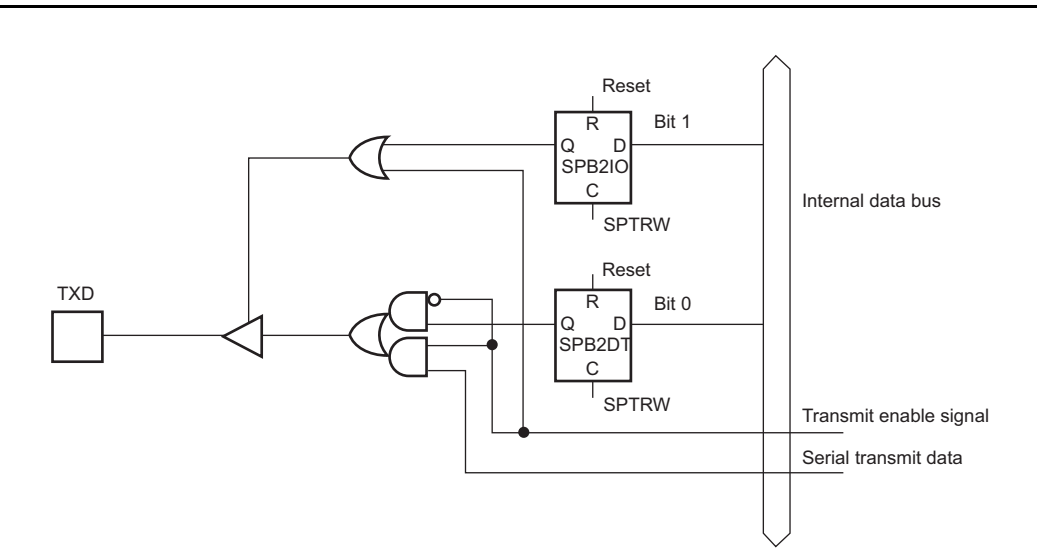
Figure 33.20 CTS2IO Bit and CTS2DT Bit in the SPTR Register, and CTS# Pin



SPTRW: SPTR write

Note 1. These signals control the SCK pin according to the settings of the CM bit in SMR and CKE[1:0] bits in SCR.

Figure 33.21 SCKIO Bit and SCKDT Bit in the SPTR Register, and SCK Pin



SPTRW: SPTR write

Figure 33.22 SPB2IO Bit and SPB2DT Bit in the SPTR Register, and TXD Pin

33.7 Noise Cancellation

Figure 33.23 shows the configuration of the noise filter used for noise cancellation. The noise filter consists of a two-stage flip-flop circuits and a match detection circuit. When the input signals of the noise filter and the output signals of the two-stage flip-flop circuits completely match, the matched level is conveyed as an internal signal. Unless otherwise matched, the previous value is retained. (When the levels sampled on three consecutive cycles of the sampling clock of the noise filter match, the signal is considered valid. If three consecutive sampled values do not match, the signal is considered to be noise rather than a received signal).

In asynchronous mode, the noise cancellation can be applied to the receive signal input to the RXDn pin. The receive level of the RXDn pin is taken in the flip-flop circuit of the noise filter on the base clock (the clock with a frequency 16, 8, or 4 times the transfer rate*1).

If the base clock is stopped once with the noise filter enabled and then the base clock input is restarted again, the noise filter operation resumes from the state where the clock was stopped. When SCR.RE is set to 0 during input of the base clock, the noise filter outputs 0 as the internal RxDn signal. The internal match detector continues operating even while operations for reception are stopped, and the result from the last time previous consecutive samples matched is output at the same time as operations for reception are resumed.

Note 1. A frequency 16 times bit rate when the SEMR.ABCS0 bit and the SEMR.BGDM bit are both 0, a frequency 8 times bit rate when either the SEMR.ABCS0 bit or the SEMR.BGDM bit is 1, and a frequency 4 times bit rate when the SEMR.ABCS0 bit and the SEMR.BGDM bit are both 1.

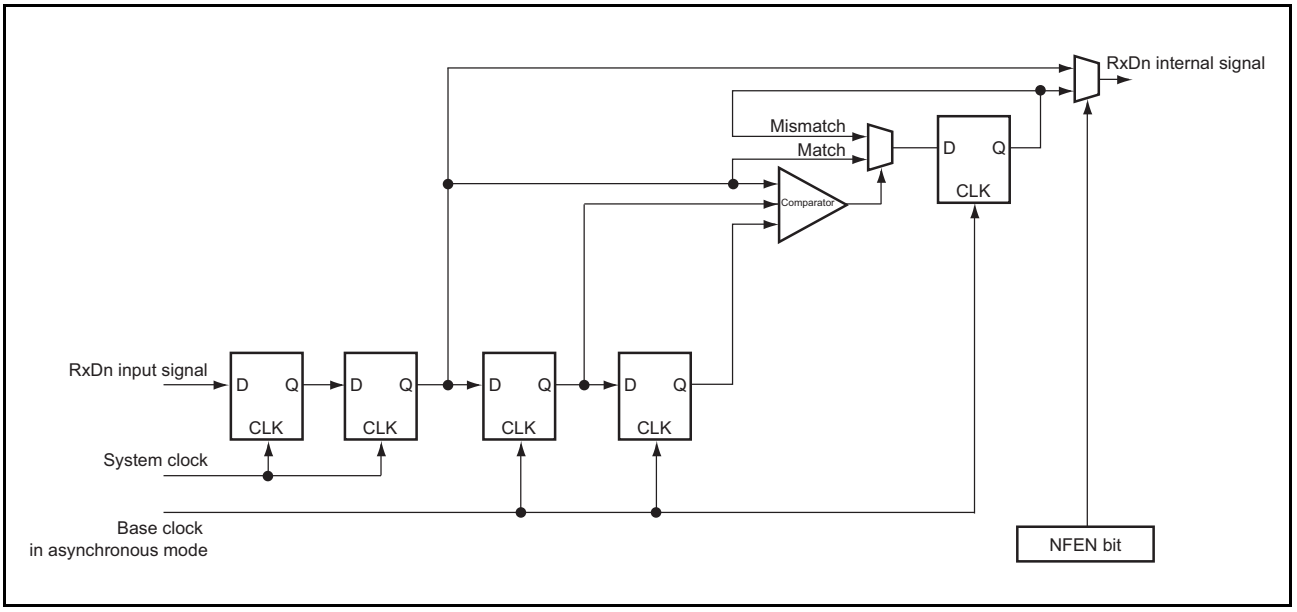


Figure 33.23 Block Diagram of Digital Noise Filter Circuit

33.8 Usage Notes

The following is the notes on using the SCIFA.

33.8.1 FTDR Register Writing and TDFE Flag

The TDFE flag in the serial status register (FSR) is set when the number of transmit data bytes written in the transmit FIFO data register (FTDR) has fallen below the transmission trigger number set by bits TTRG[1:0] in the FIFO control register (FCR) or bits TFTC[4:0] in the FIFO trigger control register (FTCR). After the TDFE flag is set, transmit data up to the number of empty bytes in the FTDR register can be written, allowing efficient continuous transmission.
However, if the number of data bytes written in the FTDR register is equal to or less than the specified transmission trigger number, the TDFE flag will be set to 1 again even after being read as 1 and cleared to 0.
In case of data writing to the FTDR register by the DMAC, the FSR.TDFE flag remains 1 after the DMAC transfer completes. However, DMAC transfer is possible regardless of the FSR.TDFE flag setting.
The number of transmit data bytes in the FTDR register can be checked by the 8 higher-order bits of the FIFO data count register (FDR).

33.8.2 FRDR Register Reading and RDF Flag

The RDF flag in the serial status register (FSR) is set when the number of receive data bytes in the receive FIFO data register (FRDR) has become equal to or greater than the reception trigger number set by bits RTRG[1:0] in the FIFO control register (FCR) or bits RFTC[4:0] in the FIFO trigger control register (FTCR). After the RDF flag is set, receive data equivalent to the trigger number can be read from the FRDR register, allowing efficient continuous reception.
However, if the number of data bytes in the FRDR register exceeds the reception trigger number, the RDF flag will be set to 1 again even after being read as 1 and cleared to 0.
In case of data reading from the FRDR register by the DMAC, the FSR.RDF flag remains 1 after the DMAC transfer completes. However, DMAC transfer is possible regardless of the FSR.RDF flag setting.
The number of receive data bytes in the FRDR register can be checked by the 8 lower-order bits of the FIFO data count register (FDR).

33.8.3 Break Detection and Processing

When a framing error (FER) is detected, a break signal can be detected by reading the RXD pin value directly. In a break, the input from the RXD pin becomes all low. Therefore, the FER flag in the serial status register (FSR) is set to 1 and the parity error flag (PER) may also be set to 1.
Upon detection of a break signal, the SCIFA stops the received data transfer to the FRDR register but continues the receive operation.

33.8.4 Writing to the SPTR Register

b6, b4, b2, and b0 of the SPTR register respectively indicate the input status of their corresponding pins. (See the description of each bit of section 33.2.12, Serial Port Register (SPTR) for details.)
Writings to these bits in 1-bit unit are handled as read-modify-write, which may lead to undesired values to be written. To avoid this, when modifying the SPB2DT or SPB2IO bit, for example, write the other bit (the bit used in combination) at the same time.

33.8.5 Break Signal Transmission

The output signal from the TXD pin is determined by the SPB2IO bit and the SPB2DT bit in the serial port register (SPTR). The break signal can be sent by using these bits.
The TXD pin does not function as a transmit data output pin during the period from when the SCIFA is initialized to when the TE bit in the SCR register is set to 1 (transmission possible). The TXD pin status during this period is replaced by the SPB2DT bit value. Therefore, the SPB2IO and SPB2DT bits in the SPTR register must have been set to 1 (high output) at first (mark (high) status).

To transmit the break signal during serial transmission, set the SPB2IO bit in the SPTR register to 1, clear the SPB2DT bit to 0 (specify a low level), and then clear the TE bit in the SCR register to 0 (transmission stop). Clearing the TE bit to 0 initializes the transmitter regardless of the current transmission status, and outputs a low level from the TXD pin.

33.8.6 Receive Data Sampling Timing and Receive Margin in Asynchronous Mode

The SCIFA operates on a base clock with a frequency 16 times the transfer rate*1. In reception, the SCIFA internally latches the received data at the rising edge of the eighth base clock pulse*1. The timing is shown in Figure 33.24.

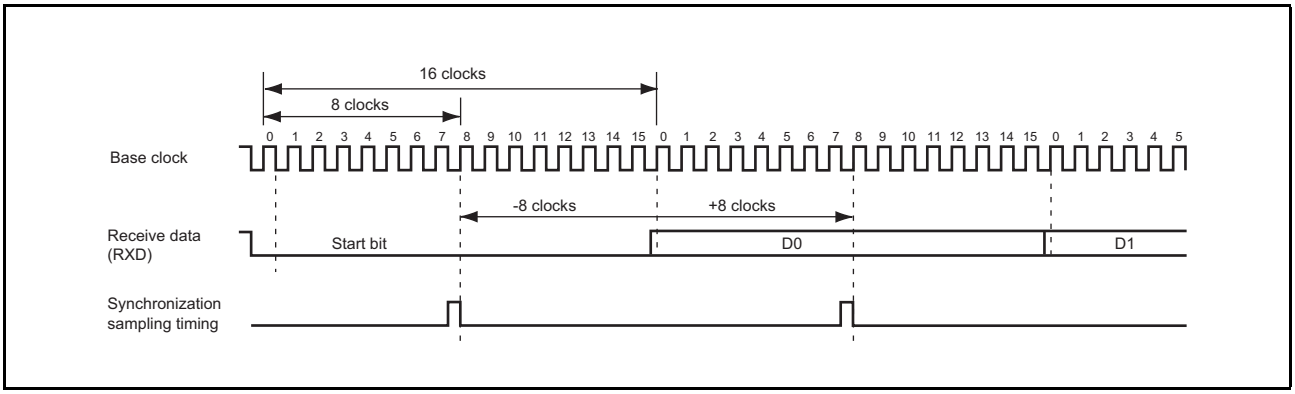

Figure 33.24 Receive Data Sampling Timing in Asynchronous Mode

Note 1. This is an example when the SEMR.ABCS0 bit is 0. When the ABCS0 bit is 1, a frequency of 8 times the bit rate is used as a base clock and receive data is sampled at the rising edge of the 4th pulse of the base clock. The receive margin in asynchronous mode can therefore be expressed as shown in equation 1.

Equation 1:

$$M = \{(0.5 - \frac{1}{2N}) - (L - 0.5)F - \frac{|D - 0.5|}{N}(1 + F)\} \times 100[\%]$$

Where: M: Receive margin (%)
N: Ratio of clock frequency to bit rate (N = 16)
D: Clock duty (D = 0 to 1.0)
L: Frame length (L = 9 to 12)
F: Absolute deviation of clock frequency

From equation 1, if F = 0 and D = 0.5, the receive margin is 46.875%, as given by equation 2.

Equation 2:

When D = 0.5 and F = 0:
M = (0.5 - 1/(2 ×16)) ×100% = 46.875%

This is a theoretical value. A reasonable margin to allow in system designs is 20% to 30%.

33.8.7 Note on FER Flag and PER Flag in Serial Status Register (FSR)

The FER flag and PER flag in the serial status register (FSR) are status flags that apply to next entry to be read from the receive FIFO data register (FRDR). After the CPU reads the receive FIFO data register, the flags of framing errors and parity errors in the receive data will be cleared. To check the received data for the states of framing errors and parity errors, only read the receive FIFO data register after reading the serial status register.

33.8.8 Notes on External Clock Input in Clock Synchronous Mode

Before setting the TE and RE bits in the serial control register (SCR) to 1, wait for four or more cycles of the peripheral operating clock after the external clock (SCK) is changed from 0 (low) to 1 (high). To input the external clock (SCK) (to start communication), wait for one or more cycles of the external clock after the TE and RE bits in the SCR register are set to 1.

33.8.9 Module Standby Mode Setting

SCIFA operation can be disabled or enabled using the standby control register. As the initial setting, the SCIFA operation is halted. Register access is enabled by clearing module standby mode. For details, refer to section 9, Low-Power Consumption Function.

33.8.10 Notes on Operation for Reception when an Internal Clock is Selected in Clock Synchronous Mode

When an internal clock is selected as the clock for reception in clock-synchronous mode, if the number of data stored through the receive FIFO data register (FRDR) becomes equal to or greater than the specified reception trigger number, the RDF flag is set, the RXIF interrupt request is generated and, at the same time, output of the synchronizing clock and reception of serial data are stopped. Once the number of data are again less than the specified reception trigger number, output of the synchronizing clock and the reception of serial data are restarted. In addition, if an internal clock is selected for reception in clock synchronous mode, the ORER flag is not set to 1 since no overrun occurs. Accordingly, overruns (indicated by the ORER flag) cannot be used as a BRIF interrupt source.

33.8.11 Notes on Initialization of the SCIFA

In the SCIFA initialization process, clearing of the TE and RE bits of the serial control register (SCR) should be taken place at the same time or the clearing of the RE bit should precede that of the TE bit. This is because clearing the TE bit to 0 while the RE bit remains 1 enables data reception and may lead to start of unintended data reception.

34. I²C Bus Interface (RIICa)

This LSI has two I2C bus interfaces (RIIC modules).
The RIIC module conforms with and provides a subset of the NXP I2C bus (Inter-IC-Bus) interface functions.

34.1 Overview

Table 34.1 lists the specifications of the RIIC, Figure 34.1 shows a block diagram of the RIIC, and Figure 34.2 shows an example of I/O pin connections to external circuits (I2C bus configuration example). Table 34.2 lists the I/O pins of the RIIC.

Table 34.1 RIIC Specifications (1 / 2)

Item	Description
Communications format	• I2C bus format • Master mode or slave mode selectable • Automatic securing of the various setup times, hold times, and bus-free times for the transfer rate
Transfer rate	Up to 400 kbps: fast mode
SCL clock	For master operation, the duty cycle of the SCL clock is selectable in the range from 4% to 96%.
Issuing and detecting conditions	Start, restart, and stop conditions are automatically generated. Start conditions (including restart conditions) and stop conditions are detectable.
Slave address	• Up to three different slave addresses can be set. • 7-bit and 10-bit address formats are supported (along with the use of both at once). • General call addresses and device ID addresses are detectable.
Acknowledgement	• For transmission, the acknowledge bit is automatically loaded. Transfer of the next data for transmission can be automatically suspended on detection of a not-acknowledge bit. • For reception, the acknowledge bit is automatically transmitted. If a wait between the eighth and ninth clock cycles has been selected, software control of the value in the acknowledge field in response to the received value is possible.
Wait function	• In reception, the following periods of waiting can be obtained by holding the SCL clock at the low level: Waiting between the eighth and ninth clock cycles Waiting between the ninth clock cycle and the first clock cycle of the next transfer
SDA output delay function	Timing of the output of transmitted data, including the acknowledge bit, can be delayed.
Arbitration	• Synchronized operation of multiple SCL clocks to avoid contention with other masters (providing support for multiple masters). • Loss in arbitration as a master Detection of mismatches of state between the SDA signal and another signal on the SDA line when a start condition is issued. Detection of a start condition being issued while in the bus busy state. Detection of mismatches of state between the data being transmitted and the signal on the SDA line in transmission as a master. • Loss in arbitration on NACK transmission Detection of mismatches of state between the data being transmitted and the signal on the SDA line in transmission of a not-acknowledge signal. • Loss in arbitration as a slave Detection of mismatches of state between the data being transmitted and the signal on the SDA line in transmission as a slave.
Timeout function	The internal timeout function is capable of detecting long-interval stop of the SCL clock.
Noise cancellation	The interface incorporates digital noise filters for both the SCL and SDA signals, and the width for noise cancellation by the filters is adjustable by software.
Interrupt sources	Four sources: • Error in transfer or occurrence of events Detection of arbitration, NACK, timeout, a start condition including a restart condition, or a stop condition • Receive-data-full (including matching with a slave address) • Transmit-data-empty (including matching with a slave address) • Transmission complete
Low-power consumption function	Module-stop state can be set.

Table 34.1 RIIC Specifications (2 / 2)

Item	Description
RIIC operating modes	• Four modes: Master transmission mode, master reception mode, slave transmission mode, and slave reception mode
Event link function (output)	Four sources: • Error in transfer or occurrence of events Detection of arbitration, NACK, timeout, a start condition including a restart condition, or a stop condition • Receive-data-full (including matching with a slave address) • Transmit-data-empty (including matching with a slave address) • Transmission complete

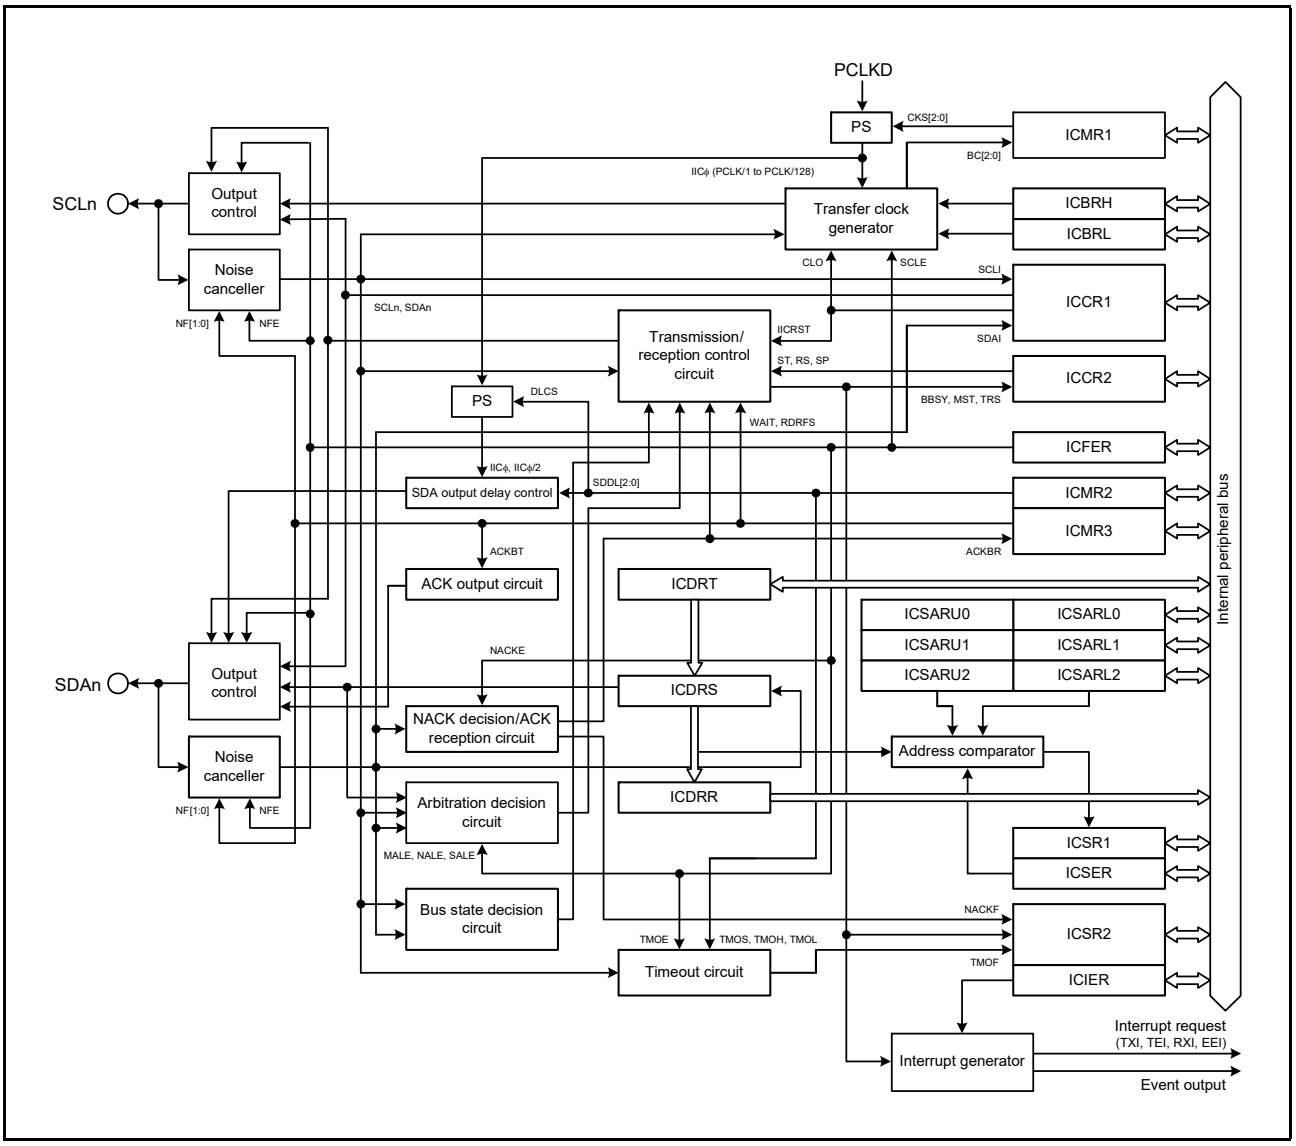

Figure 34.1 RIIC Block Diagram

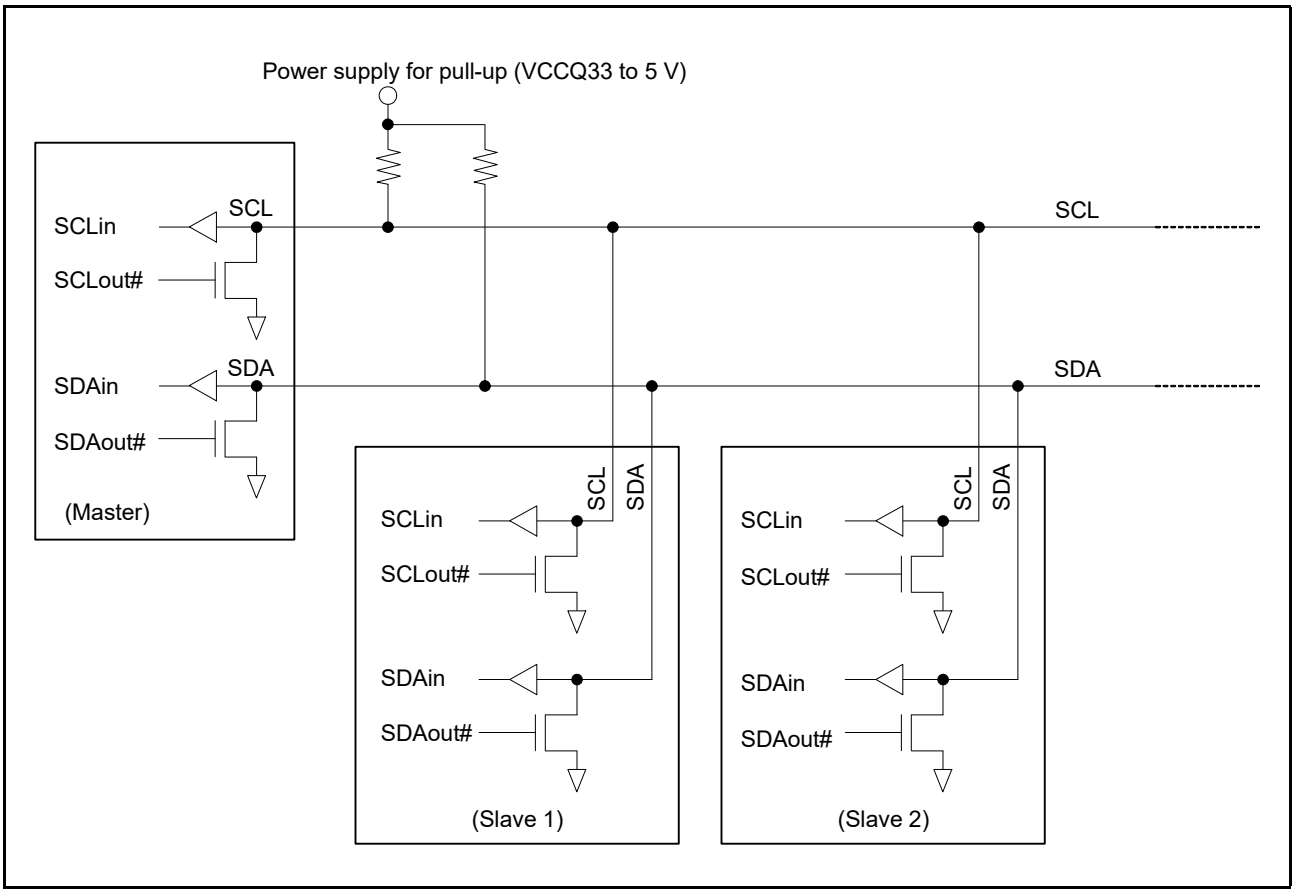

Figure 34.2 Connections to the External Circuit by the I/O Pins (I²C Bus Configuration Example)

The input level of the signals for RIIC is CMOS.

Table 34.2 Pin Configuration

Channel	Pin Name	I/O	Function
RIIC0	SCL0	I/O	RIIC0 serial clock I/O pin
	SDA0	I/O	RIIC0 serial data I/O pin
RIIC1	SCL1	I/O	RIIC1 serial clock I/O pin
	SDA1	I/O	RIIC1 serial data I/O pin

34.2 Register Descriptions

34.2.1 I²C Bus Control Register 1 (ICCR1)

The ICCR1 register controls the SDAn and SCLn signals output by the RIIC (n = 0, 1).

Address(es): RIIC0.ICCR1 A008 0900h, RIIC1.ICCR1 A008 0940h

	b7	b6	b5	b4	b3	b2	b1	b0
	ICE	IICRST	CLO	SOWP	SCLO	SDAO	SCLI	SDAI
Value after reset:	0	0	0	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b0	SDAI	SDA Line Monitor	0: SDAn line is low. 1: SDAn line is high.	R
b1	SCLI	SCL Line Monitor	0: SCLn line is low. 1: SCLn line is high.	R
b2	SDAO	SDA Output Control/Monitor	• Read: 0: SDAn pin output is low. 1: SDAn pin output is high. • Write: 0: SDAn pin output is set to low. 1: SDAn pin output is changed to high impedance. (High level output is achieved through an external pull-up resistor.)	R/W
b3	SCLO	SCL Output Control/Monitor	• Read: 0: SCLn pin output is low. 1: SCLn pin output is high. • Write: 0: SCLn pin output is set to low. 1: SCLn pin output is changed to high impedance. (High level output is achieved through an external pull-up resistor.)	R/W
b4	SOWP	SCLO/SDAO Write Protect	0: Bits SCLO and SDAO can be written. 1: Bits SCLO and SDAO are protected. (This bit is always read as 1.)	R/W
b5	CLO	Extra SCL Clock Cycle Output	0: Does not output an extra SCL clock cycle (default). 1: Outputs an extra SCL clock cycle. (The CLO bit is cleared automatically after one clock cycle is output.)	R/W
b6	IICRST	I²C Bus Interface Internal Reset	0: Releases the RIIC reset or internal reset. 1: Initiates the RIIC reset or internal reset. (Clears the bit counter and the SCLn/SDAn output latch)	R/W
b7	ICE	I²C Bus Interface Enable	0: Disable (SCLn and SDAn pins in inactive state) 1: Enable (SCLn and SDAn pins in active state) (Combined with the IICRST bit to select either RIIC or internal reset.)	R/W

SDAO Bit (SDA Output Control/Monitor) and SCLO Bit (SCL Output Control/Monitor)

These bits are used to directly control the SDAn and SCLn signals output from the RIIC.

When writing to these bits, also write 0 to the SOWP bit.

The result of setting these bits is input to the RIIC via the input buffer. When slave mode is selected, a start condition may be detected and the bus may be released depending on the bit settings.

Do not rewrite these bits during a start condition, stop condition, restart condition, or during transmission or reception. Operation after rewriting under the above conditions is not guaranteed.

When reading these bits, the state of signals output from the RIIC can be read.

CLO Bit (Extra SCL Clock Cycle Output)

This bit is used to output an extra SCL clock cycle for debugging or error processing.
Normally, set the bit to 0. Setting the bit to 1 in a normal communication state causes a communication error.
For details on this function, refer to section 34.11.2, Extra SCL Clock Cycle Output Function.

IICRST Bit (I²C Bus Interface Internal Reset)

This bit is used to reset the internal states of the RIIC.
Setting this bit to 1 initiates an RIIC reset or internal reset.
Whether an RIIC reset or internal reset is initiated is determined according to the combination with the ICE bit. Table 34.3 lists the resets of the RIIC.
The RIIC reset resets all registers and internal states of the RIIC, and the internal reset resets the bit counter (ICMR1.BC[2:0] bits), the I²C bus shift register (ICDRS), and the I²C bus status registers (ICSR1 and ICSR2) as well as the internal states of the RIIC. For the reset conditions for each register, refer to section 34.13, Resets and Register and Function States When Issuing Each Condition.
An internal reset initiated with the IICRST bit set to 1 during operation (with the ICE bit set to 1) resets the internal states of the RIIC without initializing the port settings and the control and setting registers of the RIIC when the bus or RIIC hangs up due to a communication error.
If the RIIC hangs up in a low level output state, resetting the internal states cancels the low level output state and releases the bus with the SCLn pin and SDAn pin at a high impedance.

Note: If an internal reset is initiated using the IICRST bit for a bus hang-up occurred during communication with the master device in slave mode, the states may become different between the slave device and the master device (due to the difference in the bit counter information). For this reason, do not initiate an internal reset in slave mode, but initiate restoration processing from the master device. If an internal reset is necessary because the RIIC hangs up with the SCLn line in a low level output state in slave mode, initiate an internal reset and then issue a restart condition from the master device or resume communication from the start condition issuance after issuing a stop condition. If communication is restarted by initiating a reset solely in the slave device without issuing a start condition or restart condition from the master device, synchronization will be lost because the master and slave devices operate asynchronously.

Table 34.3 RIIC Resets

IICRST	ICE	State	Specifications
1	0	RIIC reset	Resets all registers and internal states of the RIIC.
	1	Internal reset	Resets the ICMR1.BC[2:0] bits, the ICSR1, ICSR2, and ICDRS registers, and the internal states of the RIIC.

ICE Bit (I²C Bus Interface Enable)

This bit selects the active or inactive state of the SCLn and SDAn pins. It can also be combined with the IICRST bit to initiate two types of resets. See Table 34.3, RIIC Resets, for the types of resets.
Set the ICE bit to 1 when using the RIIC. The SCLn and SDAn pins are placed in the active state when the ICE bit is set to 1.
Set the ICE bit to 0 when the RIIC is not to be used. The SCLn and SDAn pins are placed in the inactive state when the ICE bit is set to 0.

34.2.2 I²C Bus Control Register 2 (ICCR2)

The ICCR2 register controls start condition issuance, restart condition issuance, and stop condition issuance.

Address(es): RIIC0.ICCR2 A008 0901h, RIIC1.ICCR2 A008 0941h

	b7	b6	b5	b4	b3	b2	b1	b0
	BBSY	MST	TRS	—	SP	RS	ST	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b1	ST	Start Condition Issuance Request	0: Does not request to issue a start condition. 1: Requests to issue a start condition.	R/W
b2	RS	Restart Condition Issuance Request	0: Does not request to issue a restart condition. 1: Requests to issue a restart condition.	R/W
b3	SP	Stop Condition Issuance Request	0: Does not request to issue a stop condition. 1: Requests to issue a stop condition.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	TRS	Transmission/Reception Mode	0: Reception mode 1: Transmission mode	R/W *1
b6	MST	Master/Slave Mode	0: Slave mode 1: Master mode	R/W *1
b7	BBSY	Bus Busy Detection Flag	0: The I²C bus is released (bus free state). 1: The I²C bus is occupied (bus busy state).	R

Note 1. When the ICMR1.MTWP bit is set to 1, the MST and TRS bits can be written to.

ST Bit (Start Condition Issuance Request)

This bit is used to request transition to master mode and issuance of a start condition.

When this bit is set to 1 to request to issue a start condition, a start condition is issued when the BBSY flag is set to 0 (bus free state).

For details on the start condition issuance, refer to section 34.10, Start Condition/Restart Condition/Stop Condition Issuing Function.

[Setting condition]

- When 1 is written to the ST bit

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the ST bit
- When a start condition has been issued (A start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

Note: Set the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 0 (bus free state). Note that setting the ST bit to 1 (start condition issuance request) when the BBSY flag is set to 1 (bus busy state) is handled as a start condition issuance error and arbitration may be lost.

RS Bit (Restart Condition Issuance Request)

This bit is used to request that a restart condition be issued in master mode.
When this bit is set to 1 to request to issue a restart condition, a restart condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).
For details on the restart condition issuance, refer to section 34.10, Start Condition/Restart Condition/Stop Condition Issuing Function.
[Setting condition]

- When 1 is written to the RS bit with the BBSY flag in ICCR2 set to 1 (1 cannot be written with the BBSY flag in ICCR2 set to 0)

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the RS bit
- When a restart condition has been issued (A start condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

Note: Do not set the RS bit to 1 while issuing a stop condition.
Note: We recommend that you issue the restart condition in master transmission mode. If 1 (requests to issue a restart condition) is written to the RS bit in slave mode, the restart condition is not issued but the RS bit remains set to 1. If the operating mode changes to master mode with the bit not being cleared, note that the restart condition may be issued.

SP Bit (Stop Condition Issuance Request)

This bit is used to request that a stop condition be issued in master mode.
When this bit is set to 1 to request to issue a stop condition, a stop condition is issued when the BBSY flag is set to 1 (bus busy state) and the MST bit is set to 1 (master mode).
For details on the stop condition issuance, refer to section 34.10, Start Condition/Restart Condition/Stop Condition Issuing Function.
[Setting condition]

- When 1 is written to the SP bit with both the BBSY flag and the MST bit in ICCR2 set to 1

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the SP bit
- When a stop condition has been issued (A stop condition is detected)
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When a start condition and a restart condition are detected
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

Note: Writing to the SP bit is not possible while the setting of the BBSY flag is 0 (bus free state).
Note: Do not set the SP bit to 1 while a restart condition is being issued.

TRS Bit (Transmission/Reception Mode)

This bit indicates transmit or reception mode.
The RIIC is in reception mode when the TRS bit is set to 0 and is in transmission mode when the bit is set to 1.
Combination of this bit and the MST bit indicates the operating mode of the RIIC.
The value of TRS bit is automatically changed to 1 for transmission mode or 0 for reception mode by issuing or detection of a start condition and setting of the R/W# bit. Although writing to the TRS bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.
[Setting conditions] One of the following conditions is satisfied:

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the BBSY flag set to 0 (bus free state) and the ST bit set to 1)
- When a restart condition is issued normally according to the restart condition issuance request (when a restart condition is detected with the RS bit set to 1)
- When the R/W# bit added to the slave address is set to 0 in master mode
- When the address received in slave mode matches the address enabled in ICSER, with the R/W# bit set to 1
- When 1 is written to the TRS bit with the MTWP bit in ICMR1 set to 1

[Clearing conditions] One of the following conditions is satisfied:

- When a stop condition is detected
- The AL (arbitration-lost) flag in ICSR2 being set to 1
- In master mode, reception of a slave address to which an R/W# bit with the value 1 is appended
- In slave mode, a match between the received address and the address enabled in ICSER when the value of the received R/W# bit is 0 (including cases where the received address is the general call address)
- In slave mode, a restart condition is detected (a start condition is detected with ICCR2.BBSY = 1 and ICCR2.MST = 0)
- When 0 is written to the TRS bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

The R/W# bit, which is contained in transmit data, indicates the transmit and receive direction. Data is transferred from the slave device to the master device when the R/W# bit is 1, or from the master device to the slave device when the R/W# bit is 0.

MST Bit (Master/Slave Mode)

This bit indicates master or slave mode.
The RIIC is in slave mode when the MST bit is set to 0 and is in master mode when the bit is set to 1. Combination of this bit and the TRS bit indicates the operating mode of the RIIC.
The value of the MST bit is automatically changed to 1 for master mode or 0 for slave mode by issuing of a start condition and issuing or detection of a stop condition, etc. Although writing to the MST bit is possible when the MTWP bit in ICMR1 is set to 1, writing to this bit is not necessary during normal usage.
[Setting conditions] One of the following conditions is satisfied:

- When a start condition is issued normally according to the start condition issuance request (when a start condition is detected with the BBSY flag set to 0 (bus free state) and the ST bit set to 1)
- When 1 is written to the MST bit with the MTWP bit in ICMR1 set to 1

[Clearing conditions] One of the following conditions is satisfied:

- When a stop condition is detected
- When the AL (arbitration-lost) flag in ICSR2 is set to 1
- When 0 is written to the MST bit with the MTWP bit in ICMR1 set to 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

BBSY Flag (Bus Busy Detection Flag)

The BBSY flag indicates whether the I2C bus is occupied (bus busy state) or released (bus free state).
This bit is set to 1 when the SDAn line changes from high to low under the condition of SCLn line = high, assuming that a start condition has been issued.
When the SDAn line changes from low to high under the condition of SCLn line = high, this bit is set to 0 after the bus free time (specified in ICBRL) start condition is not detected, assuming that a stop condition has been issued.
[Setting condition]

- When a start condition is detected

[Clearing conditions] One of the following conditions is satisfied:

- When the bus free time (specified in ICBRL) start condition is not detected after detecting a stop condition
- When 1 is written to the IICRST bit in ICCR1 with the ICE bit in ICCR1 set to 0 (RIIC reset)

34.2.3 I²CBus Mode Register 1 (ICMR1)

The ICMR1 register specifies the number of bits of the down counter and the reference clock source.

Address(es): RIIC0.ICMR1 A008 0902h, RIIC1.ICMR1 A008 0942h

	b7	b6	b5	b4	b3	b2	b1	b0
	MTWP	CKS[2:0]			BCWP	BC[2:0]		
Value after reset:	0	0	0	0	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BC[2:0]	Bit Counter	b2 b0 0 0 0: 9 bits 0 0 1: 2 bits 0 1 0: 3 bits 0 1 1: 4 bits 1 0 0: 5 bits 1 0 1: 6 bits 1 1 0: 7 bits 1 1 1: 8 bits	R/W *1
b3	BCWP	BC Write Protect	0: Enables a value to be written in the BC[2:0] bits. (This bit is read as 1.)	R/W *1
b6 to b4	CKS[2:0]	Internal Reference Clock Selection	Selects the internal reference clock source (IICϕ) for the RIIC. b6 b4 0 0 0: PCLKD/1 clock 0 0 1: PCLKD/2 clock 0 1 0: PCLKD/4 clock 0 1 1: PCLKD/8 clock 1 0 0: PCLKD/16 clock 1 0 1: PCLKD/32 clock 1 1 0: PCLKD/64 clock 1 1 1: PCLKD/128 clock	R/W
b7	MTWP	MST/TRS Write Protect	0: Disables writing to the MST and TRS bits in ICCR2. 1: Enables writing to the MST and TRS bits in ICCR2.	R/W

Note 1. Rewrite the BC[2:0] bits and set the BCWP bit to 0 at the same time.

BC[2:0] Bits (Bit Counter)

These bits function as a counter that indicates the number of bits remaining to be transferred at the detection of a rising edge on the SCLn line. Although these bits are writable and readable, it is not necessary to access these bits under normal conditions.

To write to these bits, specify the number of bits to be transferred plus one (data is transferred with an additional acknowledge bit) between transferred frames when the SCLn line is at a low level.

The values of the BC[2:0] bits return to 000b at the end of a data transfer including the acknowledge bit or when a start condition including a restart condition is detected.

34.2.4 I²C Bus Mode Register 2 (ICMR2)

The ICMR2 register specifies various settings regarding the timeout detection function and SDA output delay function.

Address(es): RIIC0.ICMR2 A008 0903h, RIIC1.ICMR2 A008 0943h

	b7	b6	b5	b4	b3	b2	b1	b0
	DLCS	SDDL[2:0]			—	TMOH	TMOL	TMOS
Value after reset:	0	0	0	0	0	1	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOS	Timeout Detection Time Selection	0: Long mode is selected. 1: Short mode is selected.	R/W
b1	TMOL	Timeout L Count Control	0: Count is disabled while the SCLn line is at a low level. 1: Count is enabled while the SCLn line is at a low level.	R/W
b2	TMOH	Timeout H Count Control	0: Count is disabled while the SCLn line is at a high level. 1: Count is enabled while the SCLn line is at a high level.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6 to b4	SDDL[2:0]	SDA Output Delay Counter	• When ICMR2.DLCS = 0 (IICϕ) b6 b4 0 0 0: No output delay 0 0 1: 1 IICϕ cycle 0 1 0: 2 IICϕ cycles 0 1 1: 3 IICϕ cycles 1 0 0: 4 IICϕ cycles 1 0 1: 5 IICϕ cycles 1 1 0: 6 IICϕ cycles 1 1 1: 7 IICϕ cycles • When ICMR2.DLCS = 1 (IICϕ/2) b6 b4 0 0 0: No output delay 0 0 1: 1 or 2 IICϕ cycles 0 1 0: 3 or 4 IICϕ cycles 0 1 1: 5 or 6 IICϕ cycles 1 0 0: 7 or 8 IICϕ cycles 1 0 1: 9 or 10 IICϕ cycles 1 1 0: 11 or 12 IICϕ cycles 1 1 1: 13 or 14 IICϕ cycles	R/W
b7	DLCS	SDA Output Delay Clock Source Selection	0: The internal reference clock (IICϕ) is selected as the clock source of the SDA output delay counter. 1: The internal reference clock divided by 2 (IICϕ/2) is selected as the clock source of the SDA output delay counter.*1	R/W

Note 1. The setting DLCS = 1 (IICϕ/2) only becomes valid when SCL is at the low level. When SCL is at the high level, the setting DLCS = 1 becomes invalid and the clock source becomes the internal reference clock (IICϕ).

TMOS Bit (Timeout Detection Time Selection)

This bit is used to select long mode or short mode for the timeout detection time when the timeout function is enabled (TMOE bit = 1 in ICFER). When this bit is set to 0, long mode is selected. When this bit is set to 1, short mode is selected. In long mode, the timeout detection internal counter functions as a 16 bit-counter. In short mode, the counter functions as a 14 bit-counter. While the SCLn line is in the state that enables this counter as specified by bits TMOH and TMOL, the counter counts up in synchronization with the internal reference clock (IICϕ) as a count source.
For details on the timeout function, refer to section 34.11.1, Timeout Function.

TMOL Bit (Timeout L Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held low when the timeout function is enabled (TMOE bit = 1 in ICFER).

TMOH Bit (Timeout H Count Control)

This bit is used to enable or disable the internal counter of the timeout function to count up while the SCLn line is held high when the timeout function is enabled (TMOE bit = 1 in ICFER).

SDDL[2:0] Bits (SDA Output Delay Counter)

The SDA output can be delayed by the SDDL[2:0] setting. This counter works with the clock source selected by the DLCS bit. The setting of this function can be used for all types of SDA output, including the transmission of the acknowledge bit.

Set the SDA output delay time to meet the I^{2}C bus standard (within the data enable time/acknowledge enable time*1) and to be within 250 ns (SCL-clock low-level period - the data setup time). Note that, if a value outside the standard is set, communication with communication devices may malfunction or it may seemingly become a start condition or stop condition depending on the bus state.

For details on this function, refer to section 34.5, Facility for Delaying SDA Output.

Note 1. Data enable time/acknowledge enable time
900 ns (up to 400 kbps: fast mode [Fm])

34.2.5 I²CBus Mode Register 3 (ICMR3)

The ICMR3 register specifies the settings for acknowledgement and wait and digital noise filter.

Address(es): RIIC0.ICMR3 A008 0904h, RIIC1.ICMR3 A008 0944h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	WAIT	RDRFS	ACKWP	ACKBT	ACKBR	NF[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	NF[1:0]	Noise Filter Stage Selection	b1 b0 0 0: Noise of up to one IICϕ cycle is filtered out (single-stage filter). 0 1: Noise of up to two IICϕ cycles is filtered out (2-stage filter). 1 0: Noise of up to three IICϕ cycles is filtered out (3-stage filter). 1 1: Noise of up to four IICϕ cycles is filtered out (4-stage filter).	R/W
b2	ACKBR	Receive Acknowledge	0: A 0 is received as the acknowledge bit (ACK reception). 1: A 1 is received as the acknowledge bit (NACK reception).	R
b3	ACKBT	Transmit Acknowledge	0: A 0 is sent as the acknowledge bit (ACK transmission). 1: A 1 is sent as the acknowledge bit (NACK transmission).	R/W *1
b4	ACKWP	ACKBT Write Protect	0: Modification of the ACKBT bit is disabled. 1: Modification of the ACKBT bit is enabled.	W*1
b5	RDRFS	RDRF Flag Set Timing Selection	0: The RDRF flag is set at the rising edge of the ninth SCL clock cycle. (The SCLn line is not held low at the falling edge of the eighth clock cycle.) 1: The RDRF flag is set at the rising edge of the eighth SCL clock cycle. (The SCLn line is held low at the falling edge of the eighth clock cycle.) Low-hold is released at the ninth cycle since a value is written to the ACKBT bit.	R/W *2
b6	WAIT	WAIT	0: No WAIT (The period between ninth clock cycle and first clock cycle is not held low.) 1: WAIT (The period between ninth clock cycle and first clock cycle is held low.) Low-hold is released by reading ICDRR.	R/W *2
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

Note 1. Write to the ACKBT bit only while the ACKWP bit is already 1. If it is attempted to write 1 to both the ACKWP and ACKBT bits at the same time, the ACKBT bit will not be set to 1.

Note 2. The WAIT and RDRFS bits are valid only in reception mode. These bits are invalid in transmission mode.

NF[1:0] Bits (Number of Noise Filter Stages Select)

These bits are used to select the number of stages in the digital noise filter.

For details on the digital noise filter function, refer to section 34.6, Digital Noise-Filter Circuits.

ACKBR Bit (Receive Acknowledge)

This bit is used to store the acknowledge bit information received from the receive device in transmission mode.
[Setting condition]

- When 1 (Not Acknowledge) is received as the acknowledge bit with the TRS bit in ICCR2 set to 1

[Clearing conditions] One of the following conditions is satisfied:

- When 0 (Acknowledge) is received as the acknowledge bit with the TRS bit in ICCR2 set to 1
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (RIIC reset)

ACKBT Bit (Transmit Acknowledge)

This bit is used to set the bit to be sent at the acknowledge timing in reception mode.
[Setting condition]

- When 1 (Not Acknowledge) is written to this bit with the ACKWP bit set to 1

[Clearing conditions] One of the following conditions is satisfied:

- When 0 (Acknowledge) is written to this bit with the ACKWP bit set to 1
- When stop condition issuance is detected (when a stop condition is detected with the SP bit in ICCR2 set to 1)
- When 1 is written to the IICRST bit in ICCR1 while the ICE bit in ICCR1 is 0 (RIIC reset)

ACKWP Bit (ACKBT Write Protect)

This bit is used to control the modification of the ACKBT bit.

RDRFS Bit (RDRF Flag Set Timing Selection)

This bit is used to select the RDRF flag set timing in reception mode and also to select whether to hold the SCLn line low at the falling edge of the eighth SCL clock cycle.
When the RDRFS bit is 0, the SCLn line is not held low at the falling edge of the eighth SCL clock cycle, and the RDRF flag is set to 1 at the rising edge of the ninth SCL clock cycle.
When the RDRFS bit is 1, the RDRF flag is set to 1 at the rising edge of the eighth SCL clock cycle and the SCLn line is held low at the falling edge of the eighth SCL clock cycle. Low-hold state is released at the ninth clock cycle or later, by writing the ACKBT bit.
After data is received with this setting, the SCLn line is automatically held low before the acknowledge bit is sent. This enables processing to send ACK (ACKBT = 0) or NACK (ACKBT = 1) according to receive data.

WAIT Bit (WAIT)

This bit is used to control whether to hold the period between the ninth SCL clock cycle and the first SCL clock cycle low until the receive data buffer (ICDRR) is completely read each time single-byte data is received in reception mode.
When the WAIT bit is 0, the receive operation is continued without holding the period between the ninth and the first SCL clock cycle low. When both the RDRFS and WAIT bits are 0, continuous receive operation is enabled with the double buffer.
When the WAIT bit is 1, the SCLn line is held low from the falling edge of the ninth clock cycle until the ICDRR value is read each time single-byte data is received. This enables receive operation in byte units.

Note: When writing 0 to the WAIT bit, be sure to read the ICDRR beforehand.

34.2.6 I²CBus Function Enable Register (ICFER)

The ICFER register specifies the settings for various arbitration functions.

Address(es): RIIC0.ICFER A008 0905h, RIIC1.ICFER A008 0945h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SCLE	NFE	NACKE	SALE	NALE	MALE	TMOE
Value after reset:	0	1	1	1	0	0	1	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOE	Timeout Function Enable	0: The timeout function is disabled. 1: The timeout function is enabled.	R/W
b1	MALE	Master Arbitration-Lost Detection Enable	0: Master arbitration-lost detection is disabled. (Disables the arbitration-lost detection function and does not clear the MST and TRS bits in ICCR2 automatically when arbitration is lost.) 1: Master arbitration-lost detection is enabled. (Enables the arbitration-lost detection function and clears the MST and TRS bits in ICCR2 automatically when arbitration is lost.)	R/W
b2	NALE	NACK Transmission Arbitration-Lost Detection Enable	0: NACK transmission arbitration-lost detection is disabled. 1: NACK transmission arbitration-lost detection is enabled.	R/W
b3	SALE	Slave Arbitration-Lost Detection Enable	0: Slave arbitration-lost detection is disabled. 1: Slave arbitration-lost detection is enabled.	R/W
b4	NACKE	NACK Reception Transfer Suspension Enable	0: Transfer operation is not suspended during NACK reception (transfer suspension disabled). 1: Transfer operation is suspended during NACK reception (transfer suspension enabled).	R/W
b5	NFE	Digital Noise Filter Circuit Enable	0: No digital noise filter circuit is used. 1: A digital noise filter circuit is used.	R/W
b6	SCLE	SCL Synchronous Circuit Enable	0: No SCL synchronous circuit is used. 1: An SCL synchronous circuit is used.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

TMOE Bit (Timeout Function Enable)

This bit is used to enable or disable the timeout function.

For details on the timeout function, refer to section 34.11.1, Timeout Function.

MALE Bit (Master Arbitration-Lost Detection Enable)

This bit is used to specify whether to use the arbitration-lost detection function in master mode. Normally, set this bit to 1.

For details on master arbitration lost detection function, see section 34.9.1, Master Arbitration-Lost Detection (MALE Bit).

NALE Bit (NACK Transmission Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when ACK is detected during transmission of NACK in reception mode (such as when slaves with the same address exist on the bus or when two or more masters select the same slave device simultaneously with different number of receive bytes).

For details on NACK transmission arbitration-lost detection function, section 34.9.2, Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit).

SALE Bit (Slave Arbitration-Lost Detection Enable)

This bit is used to specify whether to cause arbitration to be lost when a value different from the value being transmitted is detected on the bus in slave transmission mode (such as when slaves with the same address exist on the bus or when a mismatch with the transmit data occurs due to noise).

For details on slave arbitration-lost detection function, see section 34.9.3, Slave Arbitration-Lost Detection (SALE Bit).

NACKE Bit (NACK Reception Transfer Suspension Enable)

This bit is used to specify whether to continue or discontinue the transfer operation when NACK is received from the slave device in transmission mode. Normally, set this bit to 1.

When NACK is received with the NACKE bit set to 1, the next transfer operation is suspended.

When the NACKE bit is 0, the next transfer operation is continued regardless of the received acknowledge content.

For details on the NACK reception transfer suspension function, refer to section 34.8.2, NACK Reception Transfer Suspension Function.

SCLE Bit (SCL Synchronous Circuit Enable)

This bit is used to specify whether to synchronize the SCL clock with the SCL input clock. Normally, set this bit to 1.

When the SCLE bit is set to 0 (no SCL synchronous circuit used), the RIIC does not synchronize the SCL clock with the SCL input clock. In this setting, the RIIC outputs the SCL clock with the transfer rate set in ICBRH and ICBRL regardless of the SCLn line state. For this reason, if the bus load of the I^2C bus line is much larger than the specification value or if the SCL clock output overlaps in multiple masters, the short-cycle SCL clock that does not meet the specification may be output. When no SCL synchronous circuit is used, it also affects the issuance of a start condition, restart condition, and stop condition, and the continuous output of extra SCL clock cycles.

This bit must not be set to 0 except for checking the output of the set transfer rate.

For details on SCL synchronous circuit function, see section 34.4, SCL Synchronization Circuit.

34.2.7 I²C Bus Status Enable Register (ICSER)

The ICSER register specifies the settings for enabling slave addresses and ID address detection.

Address(es): RIIC0.ICSER A008 0906h, RIIC1.ICSER A008 0946h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	DIDE	—	GCAE	SAR2E	SAR1E	SAR0E
Value after reset:	0	0	0	0	1	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	SAR0E	Slave Address Register 0 Enable	0: Slave address in ICSARL0 and ICSARU0 is disabled. 1: Slave address in ICSARL0 and ICSARU0 is enabled.	R/W
b1	SAR1E	Slave Address Register 1 Enable	0: Slave address in ICSARL1 and ICSARU1 is disabled. 1: Slave address in ICSARL1 and ICSARU1 is enabled.	R/W
b2	SAR2E	Slave Address Register 2 Enable	0: Slave address in ICSARL2 and ICSARU2 is disabled. 1: Slave address in ICSARL2 and ICSARU2 is enabled.	R/W
b3	GCAE	General Call Address Enable	0: General call address detection is disabled. 1: General call address detection is enabled.	R/W
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DIDE	Device-ID Address Detection Enable	0: Device-ID address detection is disabled. 1: Device-ID address detection is enabled.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SARyE Bit (Slave Address Register y Enable) (y = 0 to 2)

This bit is used to enable or disable the slave address set in ICSARLy and ICSARUy.

When this bit is set to 1, the slave address set in ICSARLy and ICSARUy is enabled and is compared with the received slave address.

When this bit is set to 0, the slave address set in ICSARLy and ICSARUy is disabled and is ignored even if it matches the received slave address.

GCAE Bit (General Call Address Enable)

This bit is used to specify whether to ignore the general call address (0000 000b + 0 [W]: All 0) when it is received.

When this bit is set to 1, if the received slave address matches the general call address, the RIIC recognizes the received slave address as the general call address independently of the slave addresses set in ICSARLy and ICSARUy (y = 0 to 2) and performs data receive operation.

When this bit is set to 0, the received slave address is ignored even if it matches the general call address.

DIDE Bit (Device-ID Address Detection Enable)

This bit is used to specify whether to recognize and execute the Device-ID address when a device ID (1111 100b) is received in the first frame after a start condition or restart condition is detected.

When this bit is set to 1, if the received first frame matches the device ID, the RIIC recognizes that the Device-ID address has been received. When the following R/W# bit is 0 [W], the RIIC recognizes the second and the following frames as slave addresses and continues the receive operation.

When this bit is set to 0, the RIIC ignores the received first frame even if it matches the device ID address and recognizes the first frame as a normal slave address.

For details on the device-ID address detection, refer to section 34.7.3, Device-ID Address Detection.

34.2.8 I²C Bus Interrupt Enable Register (ICIER)

The ICIER register enables or disables interrupt requests regarding RIIC.

Address(es): RIIC0.ICIER A008 0907h, RIIC1.ICIER A008 0947h

	b7	b6	b5	b4	b3	b2	b1	b0
	TIE	TEIE	RIE	NAKIE	SPIE	STIE	ALIE	TMOIE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOIE	Timeout Interrupt Request Enable	0: Timeout interrupt request (TMOI) is disabled. 1: Timeout interrupt request (TMOI) is enabled.	R/W
b1	ALIE	Arbitration-Lost Interrupt Request Enable	0: Arbitration-lost interrupt request (ALI) is disabled. 1: Arbitration-lost interrupt request (ALI) is enabled.	R/W
b2	STIE	Start Condition Detection Interrupt Request Enable	0: Start condition detection interrupt request (STI) is disabled. 1: Start condition detection interrupt request (STI) is enabled.	R/W
b3	SPIE	Stop Condition Detection Interrupt Request Enable	0: Stop condition detection interrupt request (SPI) is disabled. 1: Stop condition detection interrupt request (SPI) is enabled.	R/W
b4	NAKIE	NACK Reception Interrupt Request Enable	0: NACK reception interrupt request (NAKI) is disabled. 1: NACK reception interrupt request (NAKI) is enabled.	R/W
b5	RIE	Receive Data Full Interrupt Request Enable	0: Receive data full interrupt request (RXI) is disabled. 1: Receive data full interrupt request (RXI) is enabled.	R/W
b6	TEIE	Transmit End Interrupt Request Enable	0: Transmit end interrupt request (TEI) is disabled. 1: Transmit end interrupt request (TEI) is enabled.	R/W
b7	TIE	Transmit Data Empty Interrupt Request Enable	0: Transmit data empty interrupt request (TXI) is disabled. 1: Transmit data empty interrupt request (TXI) is enabled.	R/W

TMOIE Bit (Timeout Interrupt Request Enable)

This bit is used to enable or disable timeout interrupt requests (TMOI) when the TMOF flag in ICSR2 is set to 1. A TMOI interrupt request is canceled by setting the TMOF flag or the TMOIE bit to 0.

ALIE Bit (Arbitration-Lost Interrupt Request Enable)

This bit is used to enable or disable arbitration-lost interrupt requests (ALI) when the AL flag in ICSR2 is set to 1. An ALI interrupt request is canceled by setting the AL flag or the ALIE bit to 0.

STIE Bit (Start Condition Detection Interrupt Request Enable)

This bit is used to enable or disable start condition detection interrupt requests (STI) when the START flag in ICSR2 is set to 1. An STI interrupt request is canceled by setting the START flag or the STIE bit to 0.

SPIE Bit (Stop Condition Detection Interrupt Request Enable)

This bit is used to enable or disable stop condition detection interrupt requests (SPI) when the STOP flag in ICSR2 is set to 1. An SPI interrupt request is canceled by setting the STOP flag or the SPIE bit to 0.

NAKIE Bit (NACK Reception Interrupt Request Enable)

This bit is used to enable or disable NACK reception interrupt requests (NAKI) when the NACKF flag in ICSR2 is set to 1. An NAKI interrupt request is canceled by setting the NACKF flag or the NAKIE bit to 0.

RIE Bit (Receive Data Full Interrupt Request Enable)

This bit is used to enable or disable receive data full interrupt requests (RXI) when the RDRF flag in ICSR2 is set to 1.

TEIE Bit (Transmit End Interrupt Request Enable)

This bit is used to enable or disable transmit end interrupt requests (TEI) when the TEND flag in ICSR2 is set to 1. An TEI interrupt request is canceled by setting the TEND flag or the TEIE bit to 0.

TIE Bit (Transmit Data Empty Interrupt Request Enable)

This bit is used to enable or disable transmit data empty interrupt requests (TXI) when the TDRE flag in ICSR2 is set to 1.

34.2.9 I²C Bus Status Register 1 (ICSR1)

The ICSR1 register is a status register that indicates the status of detection of various addresses.

Address(es): RIIC0.ICSR1 A008 0908h, RIIC1.ICSR1 A008 0948h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	DID	—	GCA	AAS2	AAS1	AAS0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	AAS0	Slave Address 0 Detection Flag	0: Slave address 0 is not detected. 1: Slave address 0 is detected.	R/(W) *1
b1	AAS1	Slave Address 1 Detection Flag	0: Slave address 1 is not detected. 1: Slave address 1 is detected.	R/(W) *1
b2	AAS2	Slave Address 2 Detection Flag	0: Slave address 2 is not detected. 1: Slave address 2 is detected.	R/(W) *1
b3	GCA	General Call Address Detection Flag	0: General call address is not detected. 1: General call address is detected.	R/(W) *1
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b5	DID	Device-ID Address Detection Flag	0: Device-ID address is not detected. 1: Device-ID address is detected. • This bit is set to 1 when the first frame received immediately after a start condition is detected matches a value of (device ID address (1111 100b) + 0[W]).	R/(W) *1
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Only 0 can be written to clear the flag.

AASy Flag (Slave Address y Detection Flag) (y = 0 to 2)

[Setting conditions]

For 7-bit address format: ICSARUy.FS = 0

- When the received slave address matches the SVA[6:0] value in ICSARLy with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: ICSARUy.FS = 1

- When the received slave address matches a value of (11110b + SVA[1:0] in ICSARUy) and the following address matches the ICSARLy value with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the AASy bit after reading AASy = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

For 7-bit address format: ICSARUy.FS = 0

- When the received slave address does not match the SVA[6:0] value in ICSARLy with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the frame.

For 10-bit address format: ICSARUy.FS = 1

- When the received slave address does not match a value of (11110b + SVA[1:0] in ICSARUy) with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the received slave address matches a value of (11110b + SVA[1:0] in ICSARUy) and the following address does not match the ICSARLy value with the SARyE bit in ICSER set to 1 (slave address y detection enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the frame.

GCA Flag (General Call Address Detection Flag)

[Setting condition]

- When the received slave address matches the general call address (0000 000b + 0 [W]) with the GCAE bit in ICSER set to 1 (general call address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the GCA bit after reading GCA = 1
- When a stop condition is detected
- When the received slave address does not match the general call address (0000 000b + 0 [W]) with the GCAE bit in ICSER set to 1 (general call address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

DID Flag (Device-ID Address Detection Flag)

[Setting condition]

- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID address (1111 100b) + 0 [W]) with the DIDE bit in ICSER set to 1 (Device-ID address detection is enabled)
  This flag is set to 1 at the rising edge of the ninth SCL clock cycle in the frame.

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the DID bit after reading DID = 1
- When a stop condition is detected
- When the first frame received immediately after a start condition or restart condition is detected does not match a value of (device ID address (1111 100b)) with the DIDE bit in ICSER set to 1 (Device-ID address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When the first frame received immediately after a start condition or restart condition is detected matches a value of (device ID address (1111 100b) + 0 [W]) and the second frame does not match any of slave addresses 0 to 2 with the DIDE bit in ICSER set to 1 (Device-ID address detection is enabled)
  This flag is set to 0 at the rising edge of the ninth SCL clock cycle in the frame.
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

34.2.10 I²C Bus Status Register 2 (ICSR2)

The ICSR2 register is a status register that indicates the status of detection of various conditions.

Address(es): RIIC0.ICSR2 A008 0909h, RIIC1.ICSR2 A008 0949h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDRE	TEND	RDRF	NACKF	STOP	START	AL	TMOF
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMOF	Timeout Detection Flag	0: Timeout is not detected. 1: Timeout is detected.	R/(W) *1
b1	AL	Arbitration-Lost Flag	0: Arbitration is not lost. 1: Arbitration is lost.	R/(W) *1
b2	START	Start Condition Detection Flag	0: Start condition is not detected. 1: Start condition is detected.	R/(W) *1
b3	STOP	Stop Condition Detection Flag	0: Stop condition is not detected. 1: Stop condition is detected.	R/(W) *1
b4	NACKF	NACK Detection Flag	0: NACK is not detected. 1: NACK is detected.	R/(W) *1
b5	RDRF	Receive Data Full Flag	0: ICDRR contains no receive data. 1: ICDRR contains receive data.	R/(W) *1
b6	TEND	Transmit End Flag	0: Data is being transmitted. 1: Data has been transmitted.	R/(W) *1
b7	TDRE	Transmit Data Empty Flag	0: ICDRT contains transmit data. 1: ICDRT contains no transmit data.	R

Note 1. Only 0 can be written to clear the flag.

TMOF Flag (Timeout Detection Flag)

This flag is set to 1 when the RIIC recognizes timeout after the SCLn line state remains unchanged for a certain period.

[Setting condition]

- When the SCLn line state remains unchanged for the period specified by the ICMR2.TMOH, TMOL, and TMOS bits while the ICFER.TMOE bit is 1 (the timeout function is enabled) in master mode or in slave mode and the received slave address matches.

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the TMOF bit after reading TMOF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

AL Flag (Arbitration-Lost Flag)

This flag shows that bus mastership has been lost (loss in arbitration) due to a bus conflict or some other reason when a start condition is issued or an address and data are transmitted. The RIIC monitors the level on the SDAn line during transmission and, if the level on the line does not match the value of the bit being output, sets the value of the AL flag to 1 to indicate that the bus is occupied by another device.

The RIIC can also set the flag to indicate the detection of loss of arbitration during NACK transmission in master mode or during data transmission in slave mode.

[Setting conditions] One of the following conditions is satisfied:

When master arbitration-lost detection is enabled: ICFER.MALE = 1

- When the internal SDA output state does not match the SDAn line level at the rising edge of SCL clock except for the ACK period during data (including slave address) transmission in master transmission mode (when the SDAn line is driven low while the internal SDA output is at a high level (the SDAn pin is in the high-impedance state))
- When a start condition is detected while the ST bit in ICCR2 is 1 (start condition issuance request) or the internal SDA output state does not match the SDAn line level
- When the ST bit in ICCR2 is set to 1 (start condition issuance request) with the BBSY flag in ICCR2 set to 1.

When NACK transmission arbitration-lost detection is enabled: ICFER.NALE = 1

- When the internal SDA output state does not match the SDAn line level at the rising edge of SCL clock in the ACK period during NACK transmission in reception mode

When slave arbitration-lost detection is enabled: ICFER.SALE = 1

- When the internal SDA output state does not match the SDAn line level at the rising edge of SCL clock except for the ACK period during data transmission in slave transmission mode

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the AL bit after reading AL = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

Table 34.4 Relationship between Arbitration-Lost Generation Sources and Arbitration-Lost Enable Functions

ICFER			ICSR2		
MALE	NALE	SALE	AL	Error	Arbitration-Lost Generation Source
1	×	×	1	Start condition issuance error	When internal SDA output state does not match SDAn line level when a start condition is detected while the ST bit in ICCR2 is 1
					When ST in ICCR2 is set to 1 with BBSY in ICCR2 set to 1
			1	Transmit data mismatch	When transmit data (including slave address) does not match the bus state in master transmission mode
×	1	×	1	NACK transmission mismatch	When ACK is detected during transmission of NACK in master reception mode or slave reception mode
×	×	1	1	Transmit data mismatch	When transmit data does not match the bus state in slave transmission mode

×: Don't care

START Flag (Start Condition Detection Flag)

[Setting condition]

- When a start condition (or a restart condition) is detected

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the START bit after reading START = 1
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

STOP Flag (Stop Condition Detection Flag)

[Setting condition]

- When a stop condition is detected

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the STOP bit after reading STOP = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

NACKF Flag (NACK Detection Flag)

[Setting condition]

- When acknowledge is not received (NACK is received) from the receive device in transmission mode with the NACKE bit in ICFER set to 1 (transfer suspension enabled)

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the NACKF bit after reading NACKF = 1
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

Note: When the NACKF flag is set to 1, the RIIC suspends data transmission/reception. Writing to ICDRT in transmission mode or reading from ICDRR in reception mode with the NACKF flag set to 1 does not enable data transmit/receive operation. To restart data transmission/reception, set the NACKF flag to 0.

RDRF Flag (Receive Data Full Flag)

[Setting conditions] One of the following conditions is satisfied:

- When receive data has been transferred from ICDRS to ICDRR
  This flag is set to 1 at the rising edge of the eighth or ninth SCL clock cycle (selected by the RDRFS bit in ICMR3)
- When the received slave address matches after a start condition (or a restart condition) is detected with the TRS bit in ICCR2 set to 0

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the RDRF bit after reading RDRF = 1
- When data is read from ICDRR
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

TEND Flag (Transmit End Flag)

[Setting condition]

- At the rising edge of the ninth SCL clock cycle while the TDRE flag is 1

[Clearing conditions] One of the following conditions is satisfied:

- When 0 is written to the TEND bit after reading TEND = 1
- When data is written to ICDRT
- When a stop condition is detected
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

TDRE Flag (Transmit Data Empty Flag)

[Setting conditions] One of the following conditions is satisfied:

- When data has been transferred from ICDRT to ICDRS and ICDRT becomes empty
- When the TRS bit in ICCR2 is set to 1 (including when 1 is written to the bit)
- When the received slave address matches while the TRS bit is 1

[Clearing conditions] One of the following conditions is satisfied:

- When data is written to ICDRT
- When the TRS bit in ICCR2 is set to 0 (including when 0 is written to the bit)
- When 1 is written to the IICRST bit in ICCR1 to apply an RIIC reset or an internal reset

Note: When the NACKF flag is set to 1 while the NACKE bit in ICFER is 1, the RIIC suspends data transmission/reception. Here, if the TDRE flag is 0 (next transmit data has been written), data is transferred to the ICDRS register and the ICDRT register becomes empty at the rising edge of the ninth clock cycle, but the TDRE flag is not set to 1.

34.2.11 I²C Slave Address Register Ly (ICSARLy) (y = 0 to 2)

The ICSARLy register specifies the settings for the slave address.

Address(es): RIIC0.ICSARL0 A008 090Ah, RIIC1.ICSARL0 A008 094Ah, RIIC0.ICSARL1 A008 090Ch, RIIC1.ICSARL1 A008 094Ch, RIIC0.ICSARL2 A008 090Eh, RIIC1.ICSARL2 A008 094Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	SVA[6:0]							SVA0
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SVA0	10-Bit Address LSB	A slave address is set.	R/W
b7 to b1	SVA[6:0]	7-Bit Address/10-Bit Address Lower Bits	A slave address is set.	R/W

SVA0 Bit (10-Bit Address LSB)

When the 10-bit address format is selected (ICSARUy.FS = 1), this bit functions as the LSB of a 10-bit address and forms the lower 8 bits of a 10-bit address in combination with the SVA[6:0] bits.
When the SARyE bit in ICSER is set to 1 (ICSARLy and ICSARUy enabled) and the ICSARUy.FS bit is 1, this bit is valid. While the ICSARUy.FS bit or SARyE bit is 0, the setting of this bit is ignored.

SVA[6:0] Bits (7-Bit Address/10-Bit Address Lower Bits)

When the 7-bit address format is selected (ICSARUy.FS = 0), these bits function as a 7-bit address. When the 10-bit address format is selected (ICSARUy.FS = 1), these bits function as the lower 8 bits of a 10-bit address in combination with the SVA0 bit.
While the SARyE bit in ICSER is 0, the setting of these bits is ignored.

34.2.12 I²C Slave Address Register Uy (ICSARUy) (y = 0 to 2)

The ICSARUy register specifies the format of the slave address.

Address(es): RIIC0.ICSARU0 A008 090Bh, RIIC1.ICSARU0 A008 094Bh, RIIC0.ICSARU1 A008 090Dh, RIIC1.ICSARU1 A008 094Dh, RIIC0.ICSARU2 A008 090Fh, RIIC1.ICSARU2 A008 094Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SVA[1:0]		FS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	FS	7-Bit/10-Bit Address Format Selection	0: The 7-bit address format is selected. 1: The 10-bit address format is selected.	R/W
b2, b1	SVA[1:0]	10-Bit Address Upper Bits	A slave address is set.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

FS Bit (7-Bit/10-Bit Address Format Selection)

This bit is used to select 7-bit address or 10-bit address for slave address y (in ICSARLy and ICSARUy).

When the SARyE bit in ICSER is set to 1 (ICSARLy and ICSARUy enabled) and the ICSARUy.FS bit is 0, the 7-bit address format is selected for slave address y, the SVA[6:0] setting in ICSARLy is valid, and the settings of the SVA[1:0] bits and the SVA0 bit in ICSARLy are ignored.

When the SARyE bit in ICSER is set to 1 (ICSARLy and ICSARUy enabled) and the ICSARUy.FS bit is 1, the 10-bit address format is selected for slave address y and the settings of the SVA[1:0] bits and ICSARLy are valid.

While the SARyE bit in ICSER is 0 (ICSARLy and ICSARUy disabled), the setting of the ICSARUy.FS bit is invalid.

SVA[1:0] Bits (10-Bit Address Upper Bits)

When the 10-bit address format is selected (FS = 1), these bits function as the upper 2 bits of a 10-bit address.

When the SARyE bit in ICSER is set to 1 (ICSARLy and ICSARUy enabled) and the ICSARUy.FS bit is 1, these bits are valid. While the ICSARUy.FS bit or SARyE bit is 0, the setting of these bits is ignored.

34.2.13 I²C Bus Bit Rate Low-Level Register (ICBRL)

The ICBRL register specifies the low-level period of SCL clock and the delay cycle to which the SDA signal is added.

Address(es): RIIC0.ICBRL A008 0910h, RIIC1.ICBRL A008 0950h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BRL[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BRL[4:0]	Bit Rate Low-Level Period	Low-level period of SCL clock	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

ICBRL works to generate the data setup time for automatic SCL low-hold operation (refer to section 34.8, Automatic Low-Hold Function for SCL); when the RIIC is used only in slave mode, this register needs to be set to a value longer than the data setup time*1.
ICBRL counts the low-level period with the internal reference clock source (IICϕ) specified by the CKS[2:0] bits in ICMR1.
If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRL register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

Note 1. Data setup time (tSU: DAT)
100 ns (up to 400 Kbps: fast mode [Fm])

34.2.14 I²C Bus Bit Rate High-Level Register (ICBRH)

The ICBRH register is a 5-bit register to set the high-level period of SCL clock, and ICBRH is valid in master mode. If the RIIC is used only in slave mode, this register need not set the high-level period.
ICBRH counts the high-level period with the internal reference clock source (IICϕ) specified by the CKS[2:0] bits in ICMR1.

Address(es): RIIC0.ICBRH A008 0911h, RIIC1.ICBRH A008 0951h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	BRH[4:0]				
Value after reset:	1	1	1	1	1	1	1	1

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	BRH[4:0]	Bit Rate High-Level Period	High-level period of SCL clock	R/W
b7 to b5	—	Reserved	These bits are read as 1. The write value should be 1.	R/W

If the digital noise filter is enabled (the NFE bit in ICFER is 1), set the ICBRH register to a value at least one greater than the number of stages in the noise filter. Regarding the number of stages in the noise filter, see the description of the ICMR3.NF[1:0] bits.

The I²C transfer rate and the SCL clock duty are calculated using the following expression.
Transfer rate = 1 / {[(ICBRH + 1) + (ICBRL + 1)] / IICϕ*1 + SCLn line rising time [tr] + SCLn line falling time [tf]}
Duty cycle = {SCLn line rising time [tr]*2 + (ICBRH + 1) / IICϕ} / {SCLn line falling time [tf]*2 + (ICBRL + 1) / IICϕ}

Note 1. IICϕ = Set value in ICMR1.CKS[2:0]
Note 2. The SCLn line rising time [tr] and SCLn line falling time [tf] depend on the total bus line capacitance [Cb] and the pull-up resistor [Rp]. For details, see the I²C bus standard from NXP Semiconductors.

Table 34.5 lists examples of ICBRH/ICBRL settings.

Table 34.5 Examples of ICBRH/ICBRL Settings for Transfer Rate

	Operating Frequency PCLKD (MHz)		
	75		
Transfer Rate (Kbps)	**CKS[2:0]**	**ICBRH**	**ICBRL**
10	111b	26 (FAh)	30(FEh)
50	101b	20 (F4h)	23(F7h)
100	100b	19 (F3h)	23(F7h)
400	010b	11 (EBh)	24(F8h)

Note: This is an example of the setting when the rising time (tr) of the SCLn line is 300 ns and the falling time (tf) of the SCLn line is 300 ns. For the specified values of the rising time (tr) and the falling time (tf) of the SCLn line, see the I²C bus specifications from NXP Semiconductors.

34.2.15 I²C Bus Transmit Data Register (ICDRT)

The ICDRT register stores transmit data.

Address(es): RIIC0.ICDRT A008 0912h, RIIC1.ICDRT A008 0952h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	1	1	1	1	1	1	1	1

When ICDRT detects a space in the I2C bus shift register (ICDRS), it transfers the transmit data that has been written to ICDRT to ICDRS and starts transmitting data in transmission mode.
The double-buffer structure of ICDRT and ICDRS allows continuous transmit operation if the next transmit data has been written to ICDRT while the ICDRS data is being transmitted.
ICDRT can always be read and written. Write transmit data to ICDRT once when a transmit data empty interrupt (TXI) request is generated.

34.2.16 I²C Bus Receive Data Register (ICDRR)

The ICDRR register stores receive data.

Address(es): RIIC0.ICDRR A008 0913h, RIIC1.ICDRR A008 0953h

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0

When 1 byte of data has been received, the received data is transferred from the I2C bus shift register (ICDRS) to ICDRR to enable the next data to be received.
The double-buffer structure of ICDRS and ICDRR allows continuous receive operation if the received data has been read from ICDRR while ICDRS is receiving data.
ICDRR cannot be written. Read data from ICDRR once when a receive data full interrupt (RXI) request is generated.
If ICDRR receives the next receive data before the current data is read from ICDRR (while the RDRF flag in ICSR2 is 1), the RIIC automatically holds the SCLn clock low one cycle before the RDRF flag is set to 1 next.

34.2.17 I²CBus Shift Register (ICDRS)

The ICDRS register is a shift register to transmit and receive data.

	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—

During transmission, transmit data is transferred from ICDRT to ICDRS and is sent from the SDAn pin. During reception, data is transferred from ICDRS to ICDRR after 1 byte of data has been received.
ICDRS cannot be accessed directly.

34.3 Operation

34.3.1 Communication Data Format

The I²C bus format consists of 8-bit data and 1-bit acknowledge. The frame following a start condition or restart condition is an address frame used to specify a slave device with which the master device communicates. The specified slave is valid until a new slave is specified or a stop condition is issued.
Figure 34.3 shows the I²C bus format, and Figure 34.4 shows the I²C bus timing.

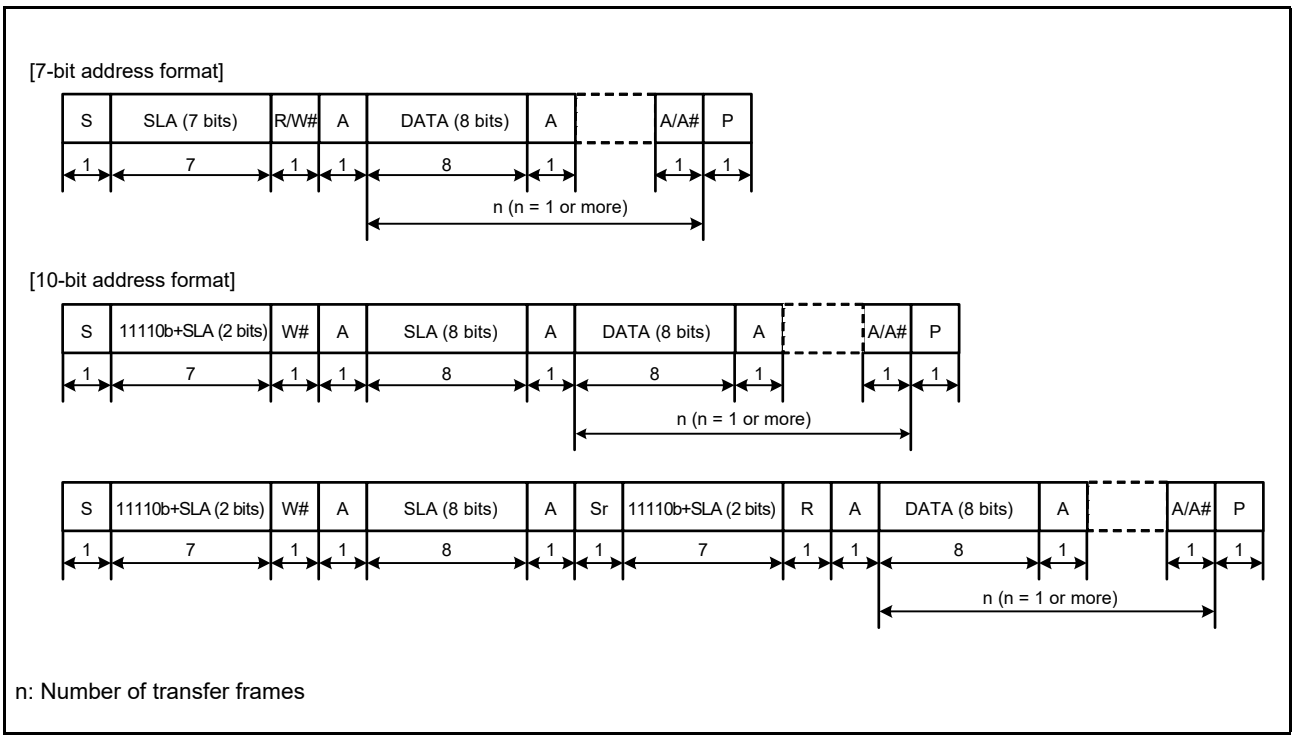

Figure 34.3 I²C Bus Format

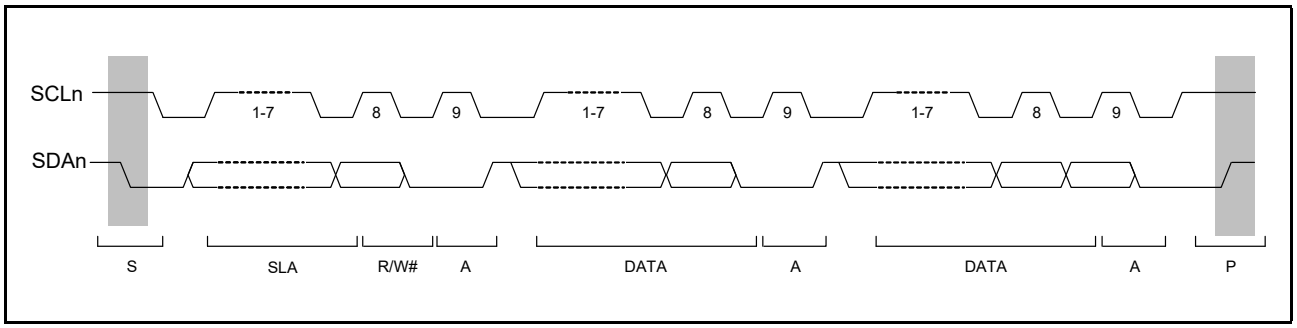

Figure 34.4 I²C Bus Timing (SLA = 7 Bits)

S: Start condition. The SDAn line is changed from the high level to the low level while the SCLn line of the master device is at a high level.

SLA: Slave address, by which the master device selects a slave device.

R/W#: Indicates the direction of data transfer: from the slave device to the master device when R/W# is 1, or from the master device to the slave device when R/W# is 0.

A: Acknowledge. The receive device drives the SDAn line low. (In master transmission mode, the slave device returns acknowledge. In master reception mode, the master device returns acknowledge.)

A#: Not Acknowledge. The receive device drives the SDAn line high.

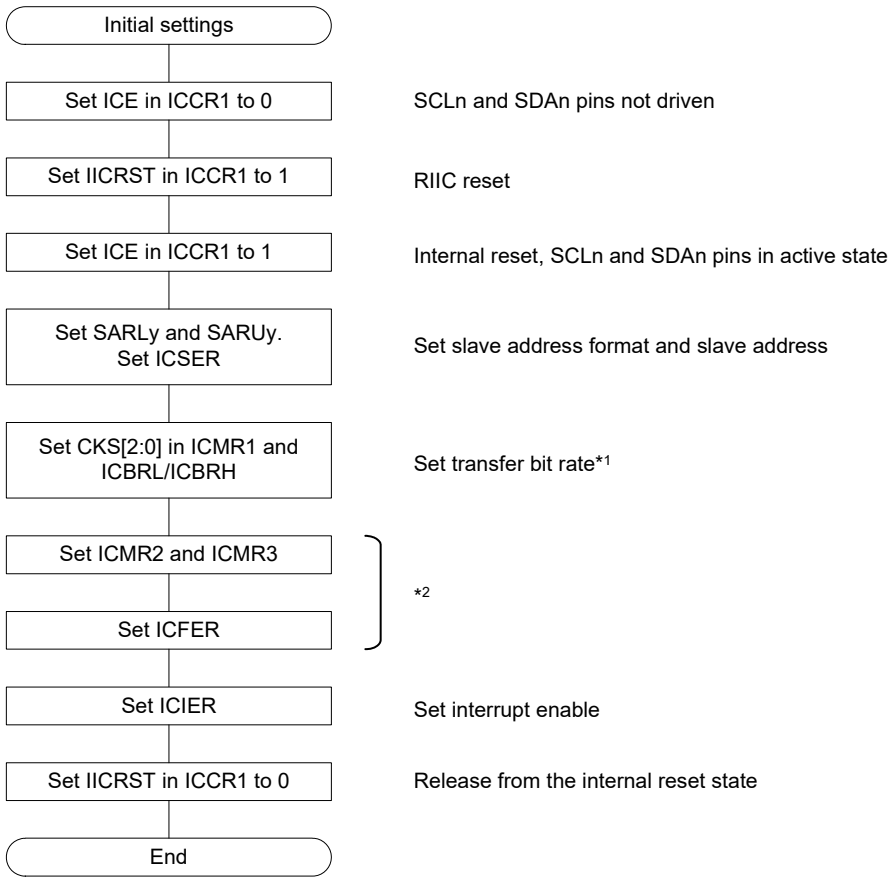
Sr: Restart condition. The SDAn line is changed from the high level to the low level after the setup time has elapsed with the SCLn line at the high level.

DATA: Transmitted or received data. The bit length of the transmitted or received data is set in ICMR1.BC[2:0].

P: Stop condition. The SDAn line is changed from the low level to the high level while the SCLn line is at a high level.

34.3.2 Initial Settings

Before starting data transmission and reception, initialize the RIIC according to the procedure in Figure 34.5.
Set the ICCR1.ICE bit to 1 (internal reset) after setting the ICCR1.IICRST bit to 1 (RIIC reset) with the ICCR1.ICE bit set to 0 (SCLn and SDAn pins in inactive state). This initializes the various flags and internal state of the ICSR1 register. After that, set registers ICSARLy, ICSARUy, ICSER, ICMR1, ICBRH, and ICBRL (y = 0 to 2), and set the other registers as necessary (for initial settings of the RIIC, see Figure 34.5). When the necessary register settings have been completed, set the ICCR1.IICRST bit to 0 (releases the RIIC reset). This step is not necessary if initialization of the RIIC has already been completed.



y = 0 to 2
Note 1. When the RIIC is used only in slave mode, set the ICBRL register to a value longer than the data setup time.
Note 2. Set these registers as necessary.

Figure 34.5 Example of RIIC Initialization Flowchart

34.3.3 Master Transmit Operation

In master transmit operation, the RIIC outputs the SCL clock and transmitted data signals as the master device, and the slave device returns acknowledgements. Figure 34.6 shows an example of usage of master transmission and Figure 34.7 to Figure 34.9 show the timing of operations in master transmission.
The following describes the procedure and operations for master transmission.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
(2) Read the BBSY flag in ICCR2 to check that the bus is open, and then set the ST bit in ICCR2 to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. At the same time, the BBSY flag and the START flag in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the internal levels for the SDA output state and the levels on the SDAn line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the MST and TRS bits in ICCR2 are automatically set to 1, placing the RIIC in master transmission mode. The TDRE flag in ICSR2 is also automatically set to 1 in response to setting of the TRS bit to 1.
(3) Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the slave address and the R/W# bit) to ICDRT. Once the data for transmission are written to ICDRT, the TDRE flag is automatically set to 0, the data are transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. After the byte containing the slave address and R/W# bit has been transmitted, the value of the TRS bit is automatically updated to select master transmit or master reception mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 0, the RIIC continues in master transmission mode.
Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
For data transmission with an address in the 10-bit format, start by writing 1111 0b, the 2 higher-order bits of the slave address, and W to ICDRT as the first address transmission. Then, as the second address transmission, write the 8 lower-order bits of the slave address to ICDRT.
(4) After confirming that the TDRE flag in ICSR2 is 1, write the data for transmission to the ICDRT register. The RIIC automatically holds the SCLn line low until the data for transmission are ready or a stop condition is issued.
(5) After all bytes of data for transmission have been written to the ICDRT register, wait until the value of the TEND flag in ICSR2 returns to 1, and then set the SP bit in ICCR2 to 1 (stop condition issuance request). Upon receiving a stop condition issuance request, the RIIC issues the stop condition.
(6) Upon detecting the stop condition, the RIIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave reception mode. Furthermore, it automatically sets the TDRE and TEND flags in ICSR2 to 0, and sets the STOP flag in ICSR2 to 1.
(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

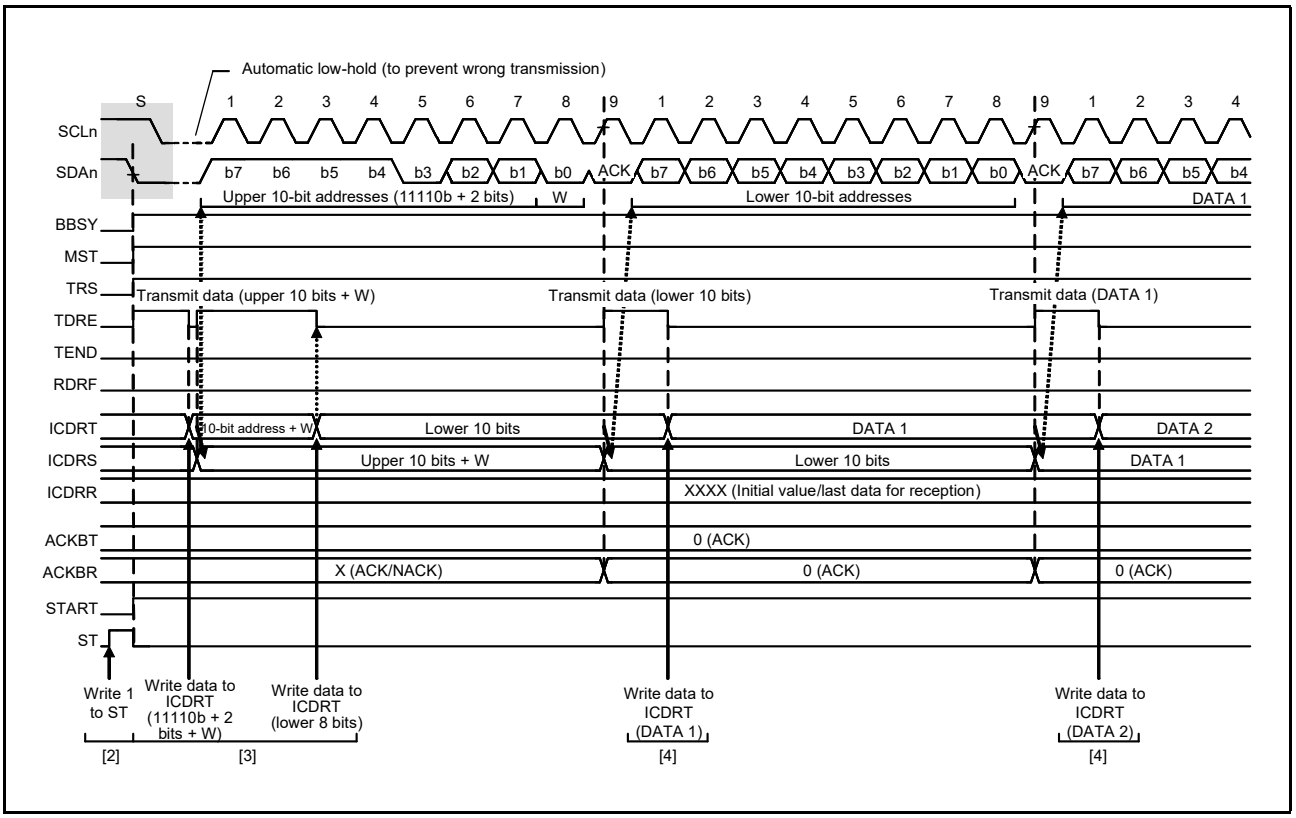

Figure 34.8 Master Transmit Operation Timing (2) (10-Bit Address Format)

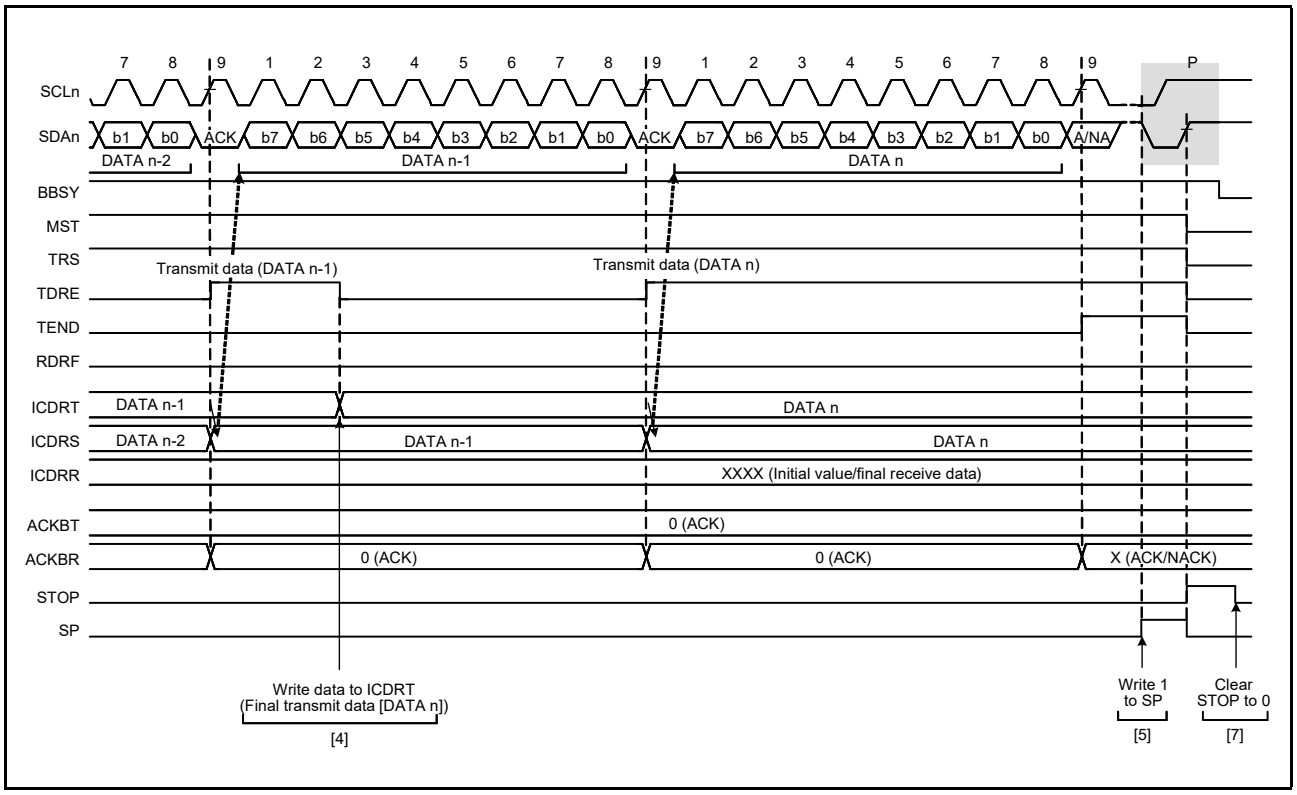

Figure 34.9 Master Transmit Operation Timing (3)

34.3.4 Master Receive Operation

In master receive operation, the RIIC as a master device outputs the SCL clock, receives data from the slave device, and returns acknowledgements. Since the RIIC must start by sending a slave address to the corresponding slave device, this part of the procedure is performed in master transmission mode, but the subsequent steps are in master reception mode. Figure 34.10 and Figure 34.11 show examples of usage of master reception in the 7-bit address format and Figure 34.12 to Figure 34.14 show the timing of operations in master reception.
The following describes the procedure and operations for master reception.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
(2) Read the BBSY flag in ICCR2 to check that the bus is open, and then set the ST bit in ICCR2 to 1 (start condition issuance request). Upon receiving the request, the RIIC issues a start condition. When the RIIC detects the start condition, the BBSY flag and the START flag in ICSR2 are automatically set to 1 and the ST bit is automatically set to 0. At this time, if the start condition is detected and the levels for the SDA output and the levels on the SDAn line have matched while the ST bit is 1, the RIIC recognizes that issuing of the start condition as requested by the ST bit has been successfully completed, and the MST and TRS bits in ICCR2 are automatically set to 1, placing the RIIC in master transmission mode. The TDRE flag in ICSR2 is also automatically set to 1 in response to setting of the TRS bit to 1.
(3) Check that the TDRE flag in ICSR2 is 1, and then write the value for transmission (the first byte indicates the slave address and value of the R/W# bit) to ICDRT. Once the data for transmission are written to ICDRT, the TDRE flag is automatically set to 0, the data are transferred from ICDRT to ICDRS, and the TDRE flag is again set to 1. Once the byte containing the slave address and R/W# bit has been transmitted, the value of the ICCR2.TRS bit is automatically updated to select transmit or reception mode in accord with the value of the transmitted R/W# bit. If the value of the R/W# bit was 1, the TRS bit is set to 0 on the rising edge of the ninth cycle of SCL clock, placing the RIIC in master reception mode. At this time, the TDRE flag is set to 0 and the ICSR2.RDRF flag is automatically set to 1.
Since the ICSR2.NACKF flag being 1 at this time indicates that no slave device recognized the address or there was an error in communications, write 1 to the ICCR2.SP bit to issue a stop condition.
For master reception from a device with a 10-bit address, start by using master transmission to issue the 10-bit address, and then issue a restart condition. After that, transmitting 1111 0b, the two higher-order bits of the slave address, and the R bit places the RIIC in master reception mode.
(4) Dummy read ICDRR after confirming that the RDRF flag in ICSR2 is 1; this makes the RIIC start output of the SCL clock and start data reception.
(5) After 1 byte of data has been received, the RDRF flag in ICSR2 is set to 1 on the rising edge of the eighth or ninth cycle of SCL clock (the clock signal) as selected by the RDRFS bit in ICMR3. Reading out ICDRR at this time will produce the received data, and the RDRF flag is automatically set to 0 at the same time. Furthermore, the value of the acknowledgement field received during the ninth cycle of SCL clock is returned as the value set in the ICMR3.ACKBT bit. If the next byte to be received is the next to last byte, set the ICMR3.WAIT bit to 1 (for wait insertion) before reading the ICDRR (containing the second byte from last). As well as enabling NACK output even in the case of delays in processing to set the ICMR3.ACKBT bit to 1 (NACK) in step (6), due to other interrupts, etc., this fixes the SCLn line to the low level on the falling edge of the ninth clock cycle in reception of the last byte, so the state is such that issuing a stop condition is possible.
(6) When the ICMR3.RDRFS bit is 0 and the slave device must be notified that it is to end transfer for data reception after transfer of the next (final) byte, set the ICMR3.ACKBT bit to 1 (NACK).

(7) After reading out the byte before last from the ICDRR register, if the value of the ICSR2.RDRF flag is confirmed to be 1, write 1 to the SP bit in ICCR2 (stop condition issuance request) and then read the last byte from ICDRR. When ICDRR is read, the RIIC is released from the wait state and issues the stop condition after low-level output in the ninth clock cycle is completed or the SCLn line is released from the low-hold state.

(8) Upon detecting the stop condition, the RIIC automatically sets the MST and TRS bits in ICCR2 to 00b and enters slave reception mode. Furthermore, detection of the stop condition leads to setting of the ICSR2.STOP flag to 1.

(9) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

34.3.5 Slave Transmit Operation

In slave transmit operation, the master device outputs the SCL clock, the RIIC transmits data as a slave device, and the master device returns acknowledgements.
Figure 34.15 shows an example of usage of slave transmission and Figure 34.16 and Figure 34.17 show the timing of operations in slave transmission.
The following describes the procedure and operations for slave transmission.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
After initial settings, the RIIC will stay in the standby state in slave reception mode until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets the corresponding bit among ICSR1.GCA and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of the SCL clock and outputs the value set in the ICMR3.ACKBT bit as the acknowledge bit on the ninth cycle of the SCL clock.
With the 7-bit address format, if the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmission mode by setting both the TRS bit and the TDRE flag in ICSR2 to 1.
With the 10-bit address format, after receiving a matching slave address, check that the ICSR2.STOP flag and the ICSR2.RDRF flag are 0 and 1, respectively, and dummy-read the ICDRR register. Here, the received value that is dummy read is the lower-order 8 bits of the address. Following the dummy read, data reception is restarted on detection of a restart condition. If the value of the R/W# bit that was also received at this time is 1, the RIIC automatically places itself in slave transmission mode by setting both the ICCR2.TRS bit and the ICSR2.TDRE flag to 1.

(3) After the ICSR2.TDRE flag is confirmed to be 1, write the data for transmission to the ICDRT register. At this time, if the RIIC receives no acknowledge from the master device (receives an NACK signal) while the ICFER.NACKE bit is 1, the RIIC suspends transfer of the next data.

(4) Wait until the ICSR2.TEND flag is set to 1 while the ICSR2.TDRE flag is 1, after the ICSR2.NACKF flag is set to 1 or the last byte for transmission is written to the ICDRT register. When the ICSR2.NACKF flag or the TEND flag is 1, the RIIC drives the SCLn line low on the ninth falling edge of SCL clock.

(5) When the ICSR2.NACKF flag or the ICSR2.TEND flag is 1, dummy read ICDRR to complete the processing. This releases the SCLn line.

(6) Upon detecting the stop condition, the RIIC automatically sets bits ICSR1.GCA and AASy (y = 0 to 2), flags ICSR2.TDRE and TEND, and the ICCR2.TRS bit to 0, and enters slave reception mode.

(7) After checking that the ICSR2.STOP flag is 1, set the ICSR2.NACKF and STOP flags to 0 for the next transfer operation.

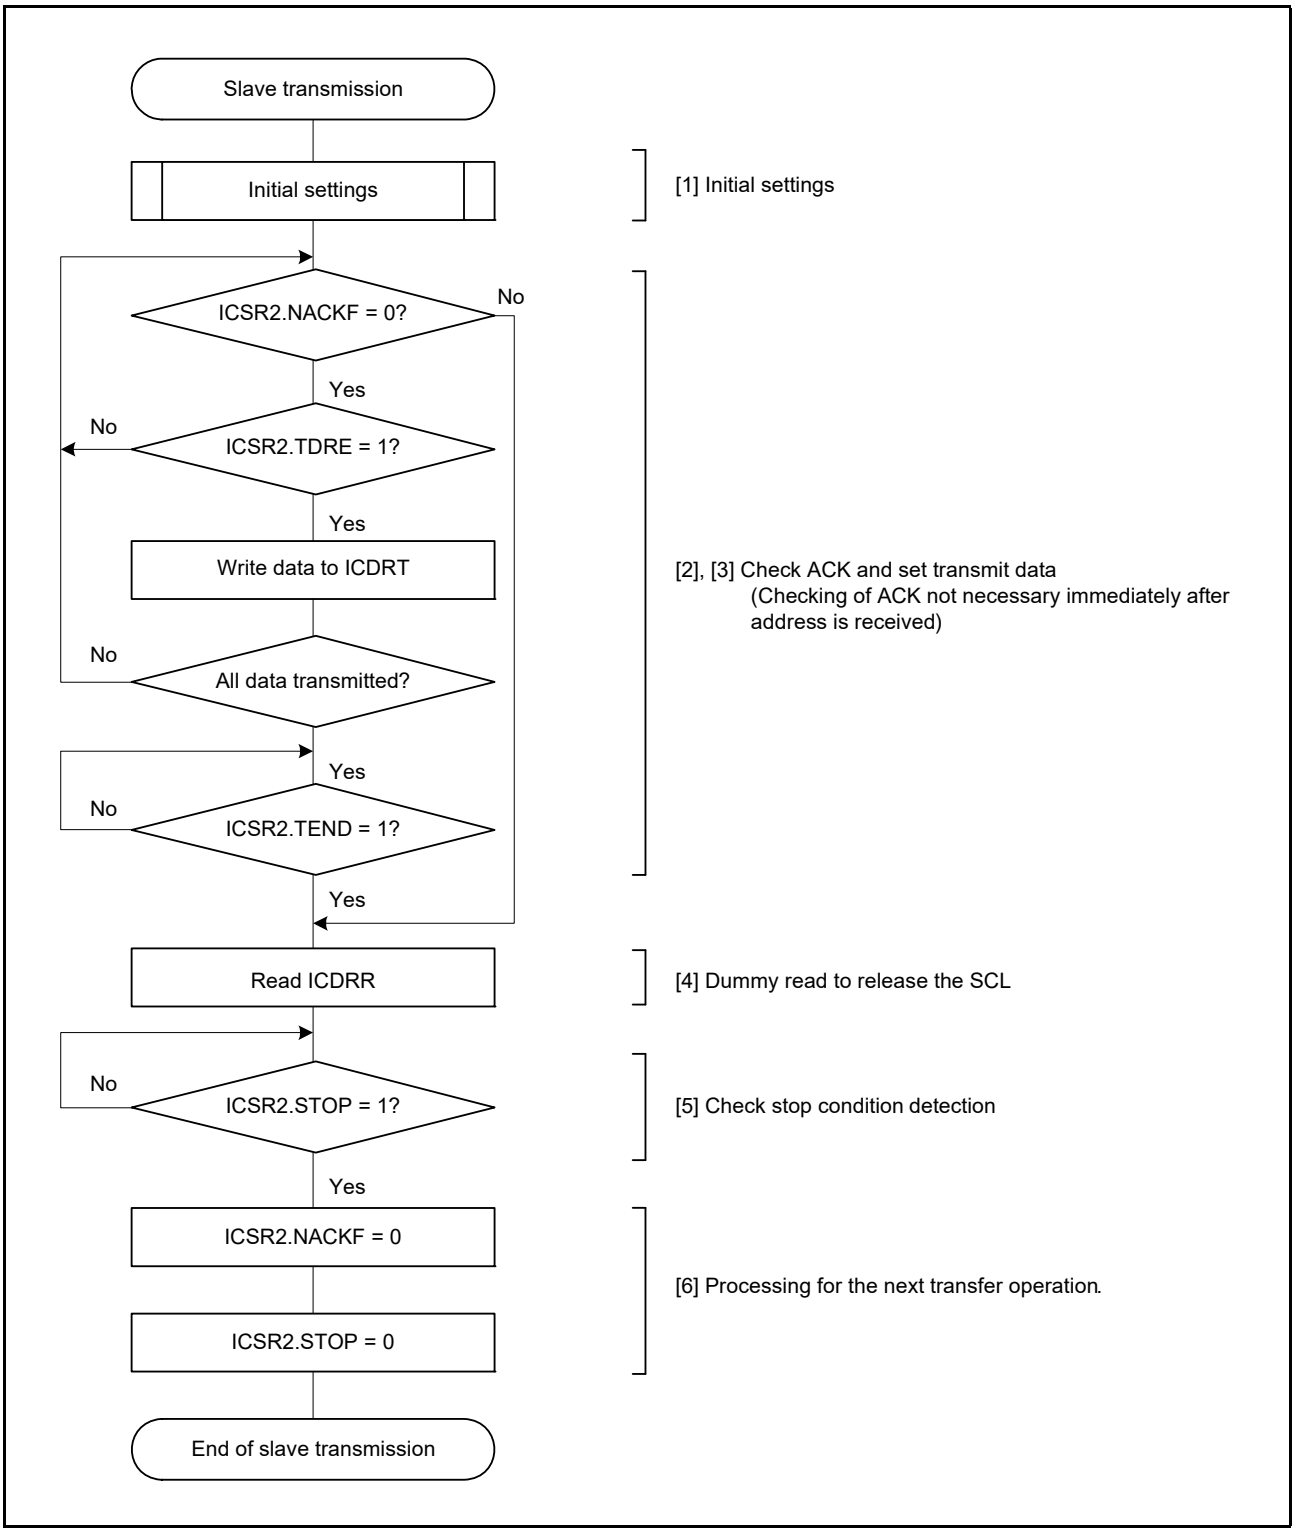

Figure 34.15 Example of Slave Transmission Flowchart

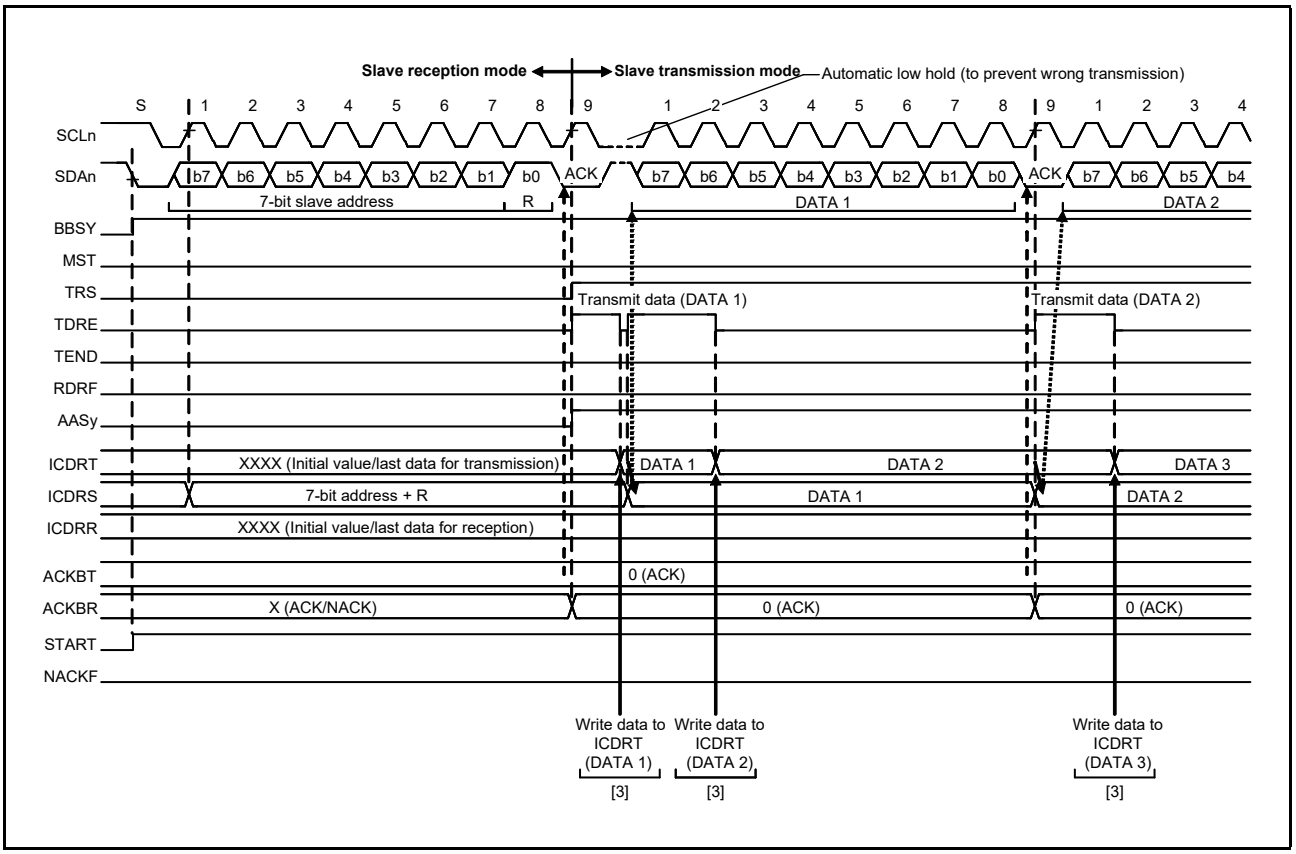

Figure 34.16 Slave Transmit Operation Timing (1) (7-Bit Address Format)

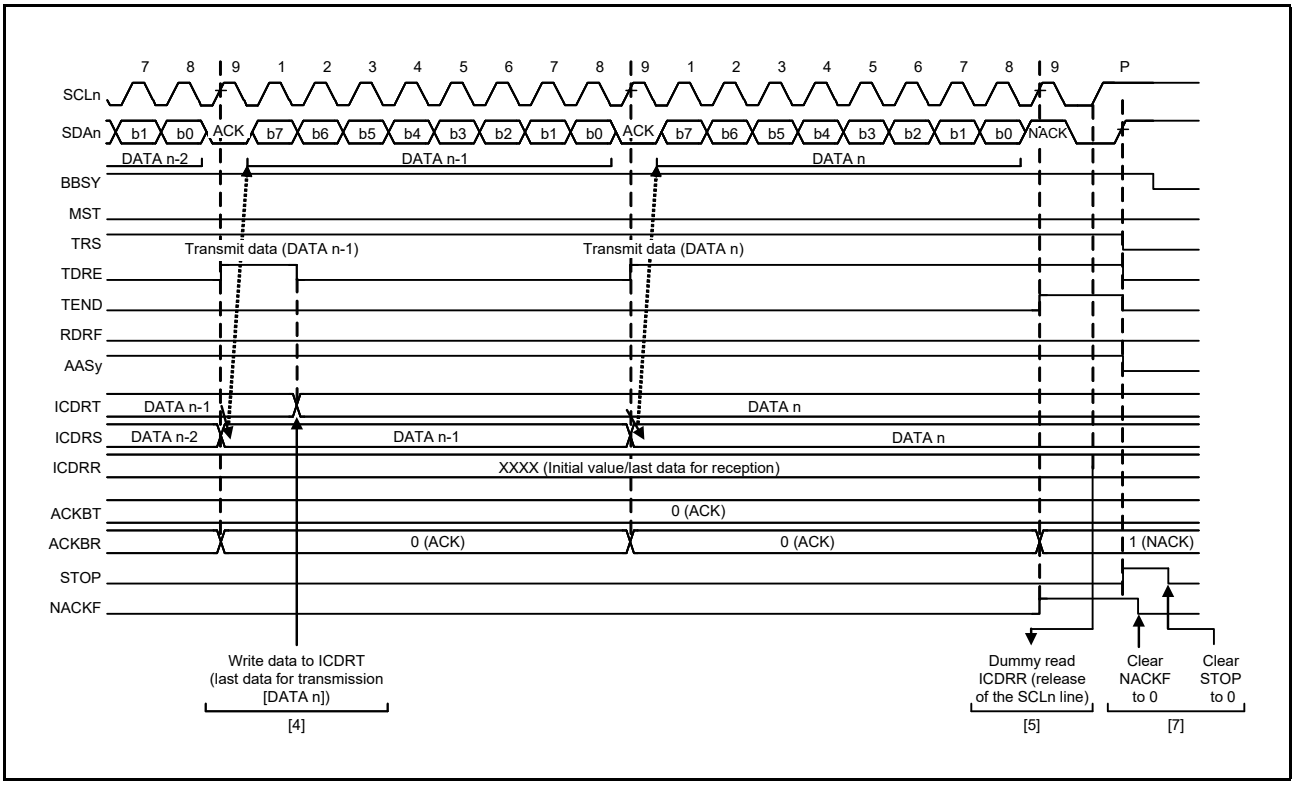

Figure 34.17 Slave Transmit Operation Timing (2)

34.3.6 Slave Receive Operation

In slave receive operation, the master device outputs the SCL clock and transmit data, and the RIIC returns acknowledgements as a slave device.

Figure 34.18 shows an example of usage of slave reception and Figure 34.19 and Figure 34.20 show the timing of operations in slave reception.

The following describes the procedure and operations for slave reception.

(1) Initial settings. For details, refer to section 34.3.2, Initial Settings.
After initial settings, the RIIC will stay in the standby state in slave reception mode until it receives a slave address that it matches.

(2) After receiving a matching slave address, the RIIC sets one of the corresponding bits ICSR1.GCA and AASy (y = 0 to 2) to 1 on the rising edge of the ninth cycle of SCL clock (the clock signal) and outputs the value set in the ICMR3.ACKBT bit to the acknowledge bit on the ninth cycle of SCL clock. If the value of the R/W# bit that was also received at this time is 0, the RIIC continues to place itself in slave reception mode and sets the RDRF flag in ICSR2 to 1.

(3) After the ICSR2.STOP flag is confirmed to be 0 and the ICSR2.RDRF flag to be 1, dummy read ICDRR (the dummy value consists of the slave address and R/W# bit when the 7-bit address format is selected, or the lower 8 bits when the 10-bit address format is selected). After the dummy-read, the RIIC clears the RDRF flag to 0 and starts reception of data.

(4) On completion of the reception of 1 byte of data, the value of the ICSR2.RDRF flag becomes 1 on the rising edge of the 8th or 9th clock cycle of the SCL clock, according to the setting made in the ICMR3.RDRFS bit. At this time, reading the ICDRR register returns the received value and the RDRF flag is automatically cleared to 0 in response. If reading of ICDRR is delayed and a next byte is received while the RDRF flag is still set to 1, the RIIC holds the SCLn line low from the falling edge of one SCL cycle before the timing with which RDRF should be set. In this case, reading ICDRR releases the SCLn line from being held at the low level.
When the ICSR2.STOP flag is 1 and the ICSR2.RDRF flag is also 1, read ICDRR until all the data is completely received.

(5) Upon detecting the stop condition, the RIIC automatically clears bits ICSR1.GCA and AASy (y = 0 to 2) to 0.

(6) After checking that the ICSR2.STOP flag is 1, set the ICSR2.STOP flag to 0 for the next transfer operation.

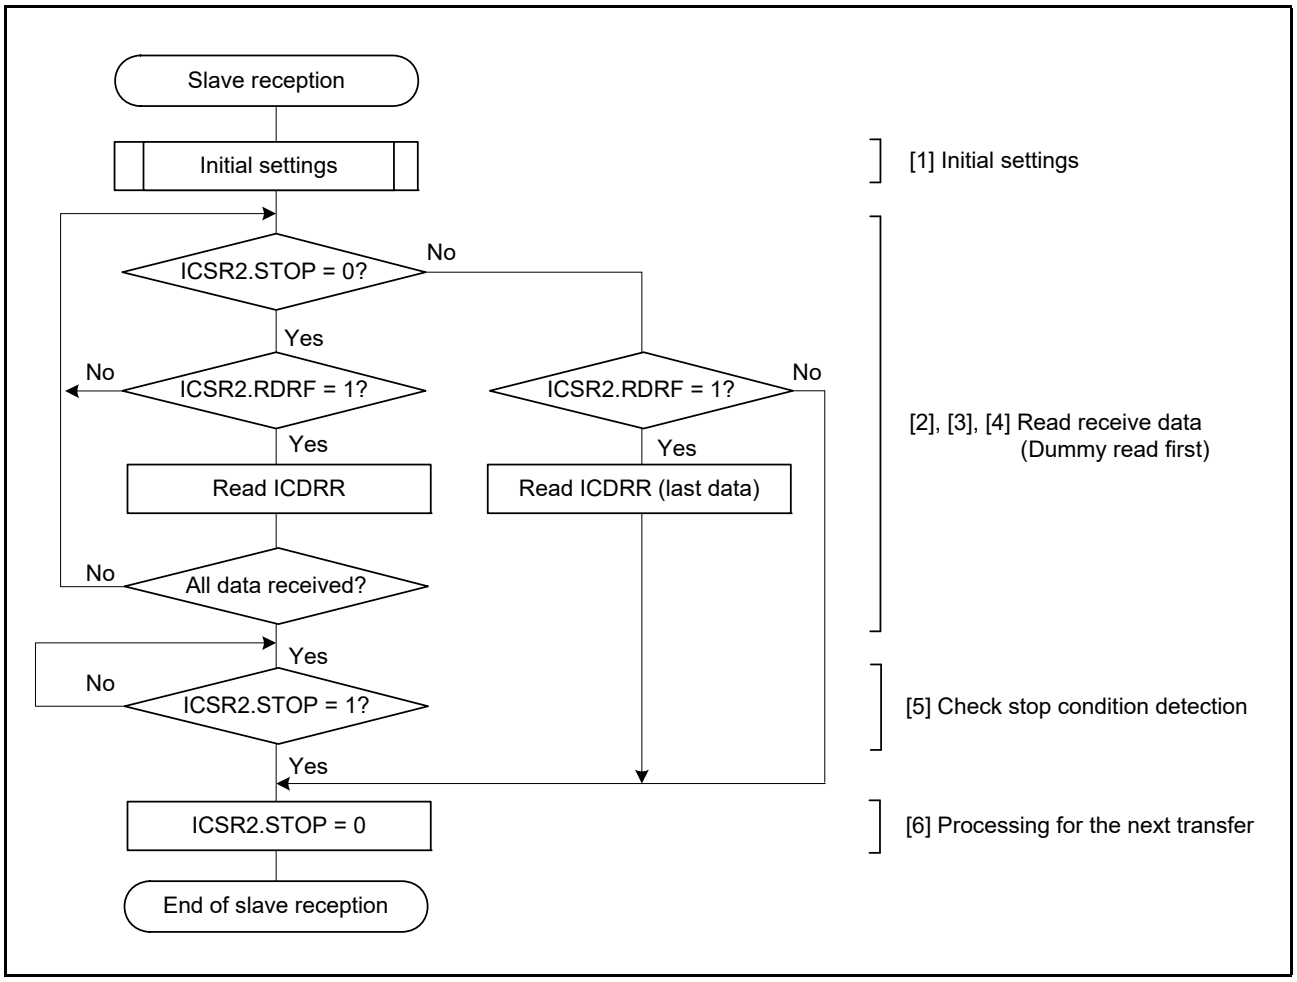

Figure 34.18 Example of Slave Reception Flowchart

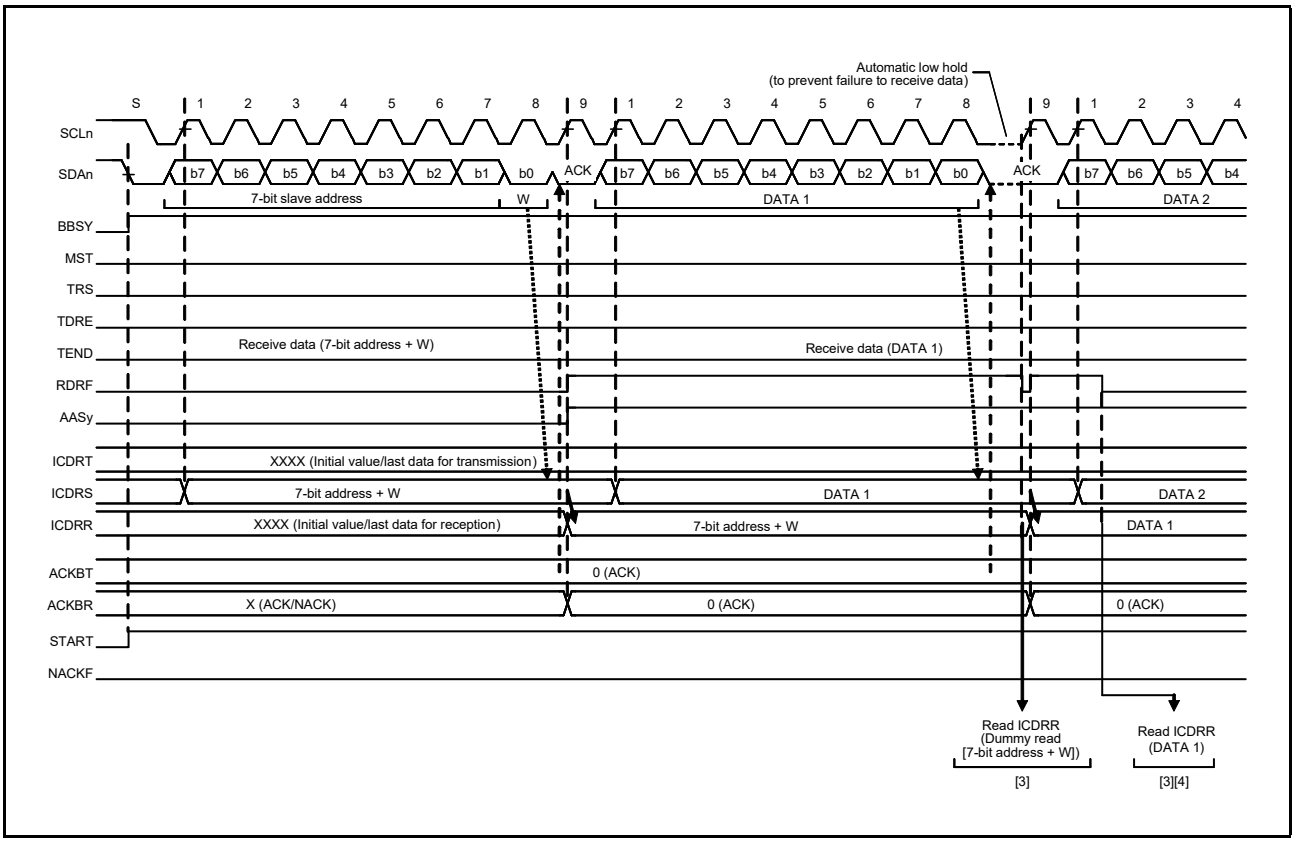

Figure 34.19 Slave Receive Operation Timing (1) (7-Bit Address Format, when RDRFS = 0)

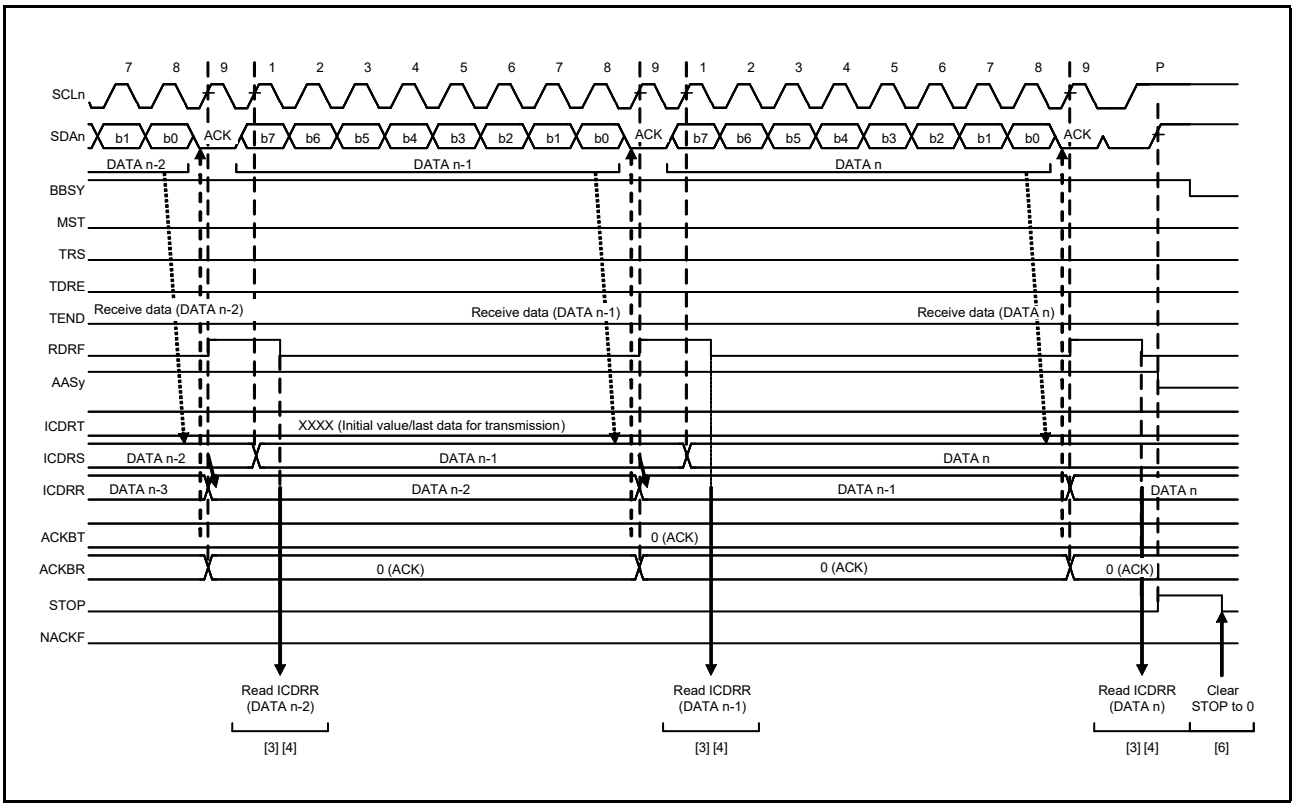

Figure 34.20 Slave Receive Operation Timing (2) (when RDRFS = 0)

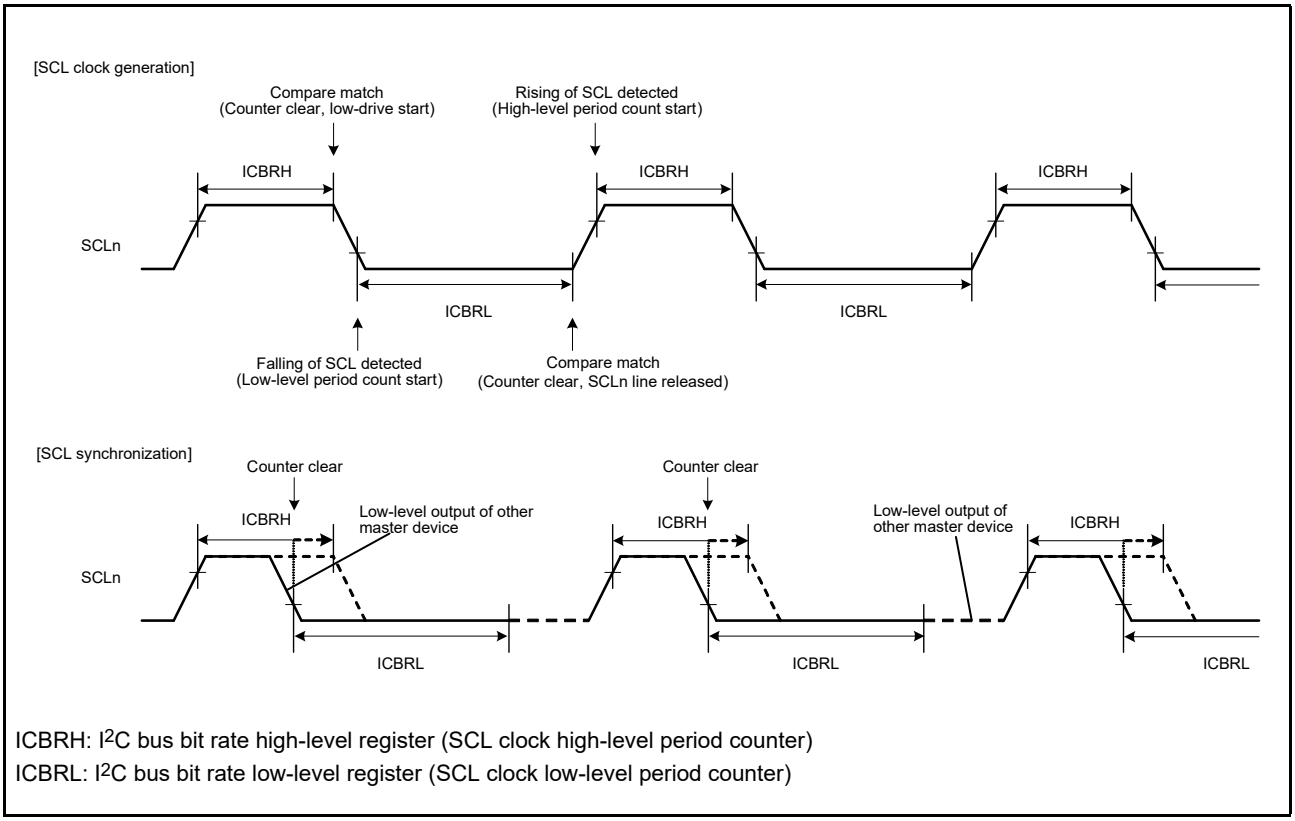
34.4 SCL Synchronization Circuit

The RIIC starts counting out the value for width at high level specified in ICBRH when it detects a rising edge on the SCLn line, drives the SCLn line low once counting of the width at high level is complete, and then generates the SCL clock. When the RIIC detects the falling edge of the SCLn line, it starts counting out the width at low level period specified in ICBRL, stops driving the SCLn line (releases the line) once counting of the width at low level is complete, and then generates the SCL clock.

If multiple master devices are connected to the I²C bus, a collision of SCL signals may arise due to contention with another master device. In such cases, the master devices have to synchronize their SCL signals. Since this synchronization of SCL signals must be bit by bit, the RIIC is equipped with a facility (the SCL synchronization circuit) to obtain bit-by-bit synchronization of the SCL clock signals by monitoring the SCLn line while in master mode.

When the RIIC has detected a rising edge on the SCLn line and thus started counting out the width at high level specified in ICBRH, and the level on the SCLn line falls because an SCL signal is being generated by another master device, the RIIC stops counting when it detects the falling edge, drives the level on the SCLn line low, and starts counting out the width at low level specified in ICBRL. When the RIIC finishes counting out the width at low level, it stops driving the SCLn line to the low level (i.e. releases the line). At this time, if the width at low level of the SCL clock signal from the other master device is longer than the width at low level set in the RIIC, the width at low level of the SCL signal will be extended. Once the width at low level for the other master device has ended, the SCL signal rises because the SCLn line has been released. When the RIIC finishes outputting the low-level period of the SCL clock, the SCLn line is released and the SCL clock rises. That is, in cases of contention of SCL signals from more than one master, the width at high level of the SCL signal is synchronized with that of the clock having the narrower width, and the width at low level of the SCL signal is synchronized with that of the clock having the broader width. However, such synchronization of the SCL signal is only enabled when the SCLE bit in ICFER is set to 1.



ICBRH: I²C bus bit rate high-level register (SCL clock high-level period counter)
ICBRL: I²C bus bit rate low-level register (SCL clock low-level period counter)

Figure 34.21 Generation and Synchronization of the SCL Signal from the RIIC

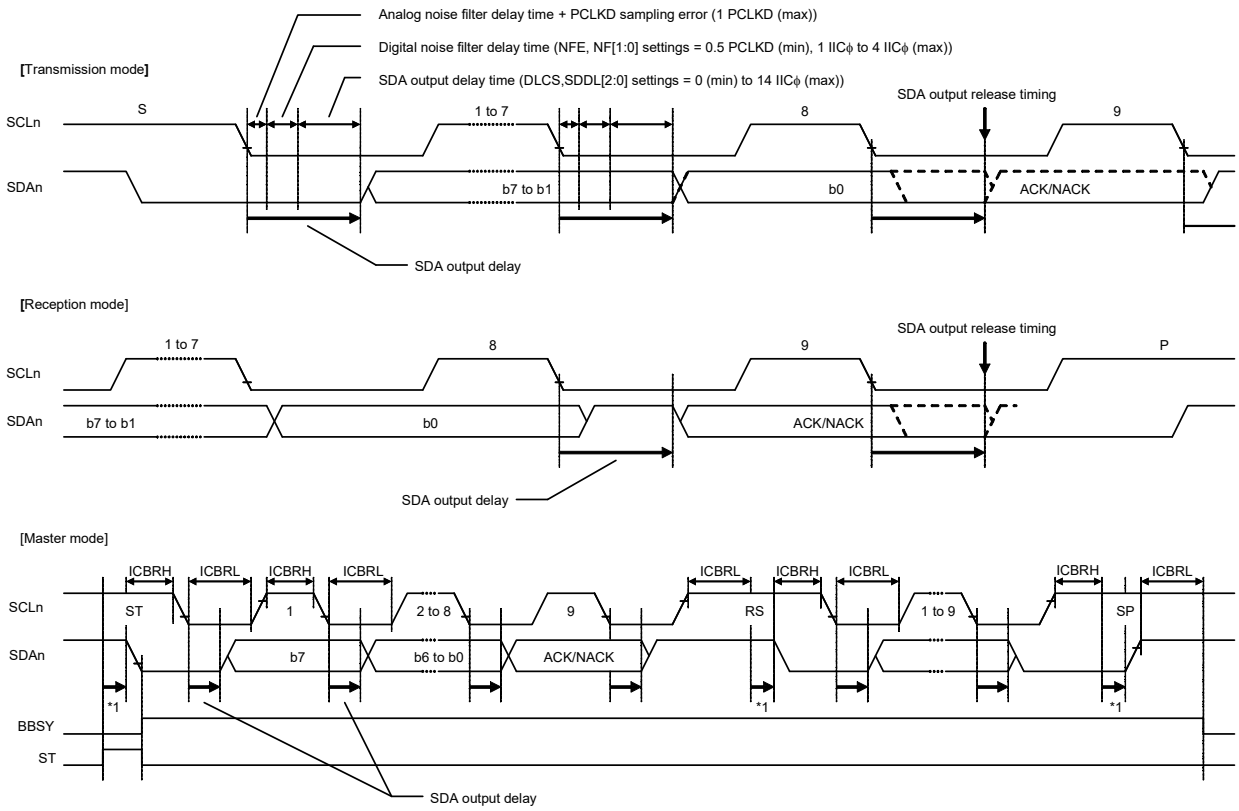
34.5 Facility for Delaying SDA Output

The RIIC module incorporates a facility for delaying output on the SDA line. The delay can be applied to all output (issuing of the start, restart, and stop conditions, data, and the ACK and NACK signals) on the SDA line.

With the SDA output delay facility, SDA output is delayed from detection of a falling edge of the SCL signal to ensure that the SDA signal is output within the interval over which the SCL clock is at the low level. Doing this leads to usage with the aim of preventing erroneous operation of communications devices.

The output delay facility is enabled by setting the SDDL[2:0] bits in ICMR2 to any value other than 000b, and disabled by setting the same bits to 000b.

While the SDA output delay facility is enabled (i.e. while the SDDL[2:0] bits in ICMR2 are set to any value other than 000b), the DLCS bit in ICMR2 selects the clock source for counting by the SDA output delay counter as the internal base clock (IICϕ) for the RIIC module or as a clock signal derived by dividing the frequency of the internal base clock by 2 (IICϕ/2). The counter counts the number of cycles set in the SDDL[2:0] bits in ICMR2. After counting of the set number of cycles of delay is completed, the RIIC module places the required output (start, restart, or stop condition, data, or an ACK or NACK signal) on the SDA line.



Note 1. The output delay facility is set by the DLCS, and SDDL[2:0] bits when a start (ST), restart (RS), or stop (SP) condition is issued.

Figure 34.22 SDA Output Delay Facility

34.6 Digital Noise-Filter Circuits

The states of the SCLn and SDAn pins are conveyed to the internal circuitry through analog noise-filter and digital noise-filter circuits. Figure 34.23 is a block diagram of the digital noise-filter circuit.

The on-chip digital noise-filter circuit of the RIIC consists of four flip-flop circuit stages connected in series and a match-detection circuit.

The number of effective stages in the digital noise filter is selected by the NF[1:0] bits in ICMR3. The selected number of effective stages determines the noise-filtering capability as a period from one to four IICϕ cycles.

The input signal to the SCLn pin (or SDAn pin) is sampled on falling edges of the IICϕ signal. When the input signal level matches the output level of the number of effective flip-flop circuit stages as selected by the NF[1:0] bits in ICMR3, the signal level is conveyed to the subsequent stage. If the signal levels do not match, the previous value is retained.

If the ratio between the frequency of the internal operating clock (PCLKD) and the transfer rate is small (e.g. data transfer at 400 Kbps with PCLKD = 4 MHz), the characteristics of the digital noise filter may lead to the elimination of needed signals as noise. In such cases, it is possible to disable the digital noise-filter circuit (by setting the ICFER.NFE bit to 0) and use only the analog noise-filter circuit.

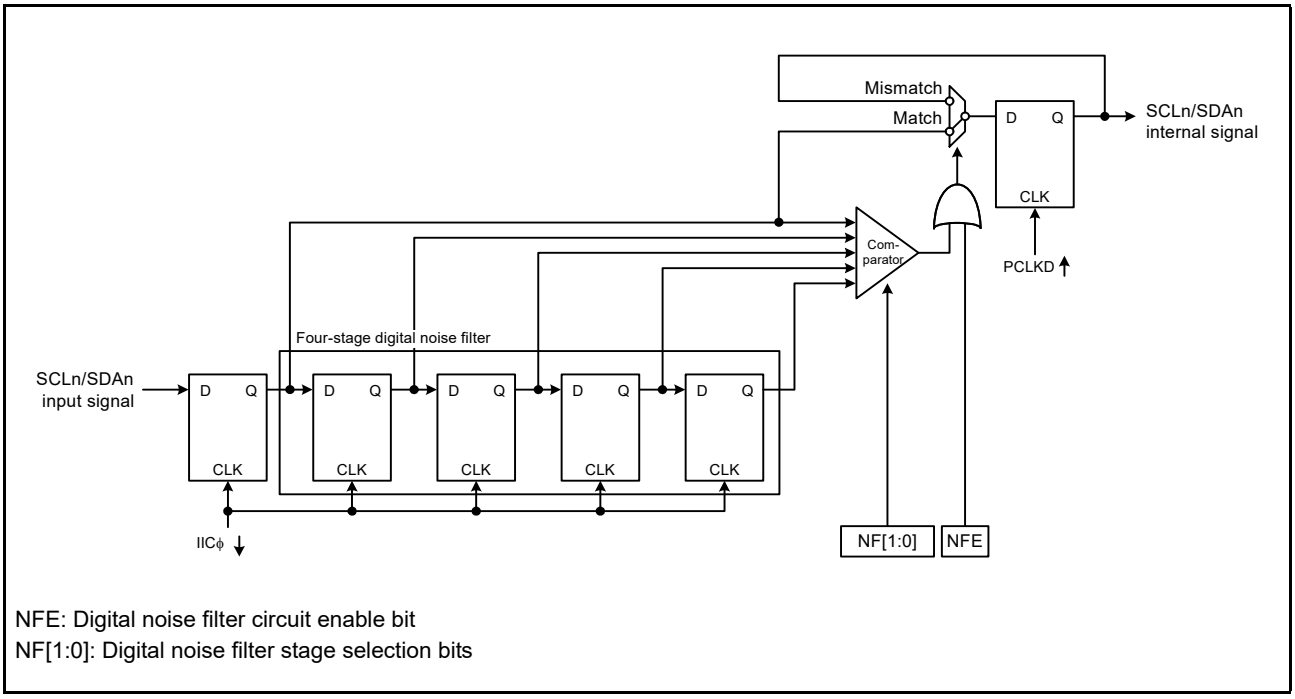


Figure 34.23 Block Diagram of Digital Noise Filter Circuit

34.7 Address Match Detection

The RIIC can set three unique slave addresses in addition to the general call address and host address, and also can set 7-bit or 10-bit slave addresses.

34.7.1 Slave-Address Match Detection

The RIIC can set three unique slave addresses, and has a slave address detection function for each unique slave address. When the SARyE bit (y = 0 to 2) in ICSER is set to 1, the slave addresses set in ICSARUy and ICSARLy (y = 0 to 2) can be detected.

When the RIIC detects a match of the set slave address, the corresponding AASy flag (y = 0 to 2) in ICSR1 is set to 1 at the rising edge of the ninth SCL clock cycle, and the RDRF flag in ICSR2 or the TDRE flag in ICSR2 is set to 1 by the following R/W# bit. This causes a receive data full interrupt (RXI) or transmit data empty interrupt (TXI) to be generated. The AASy flag is used to identify which slave address has been specified.

Figure 34.24 to Figure 34.26 show the AASy flag set timing in three cases.

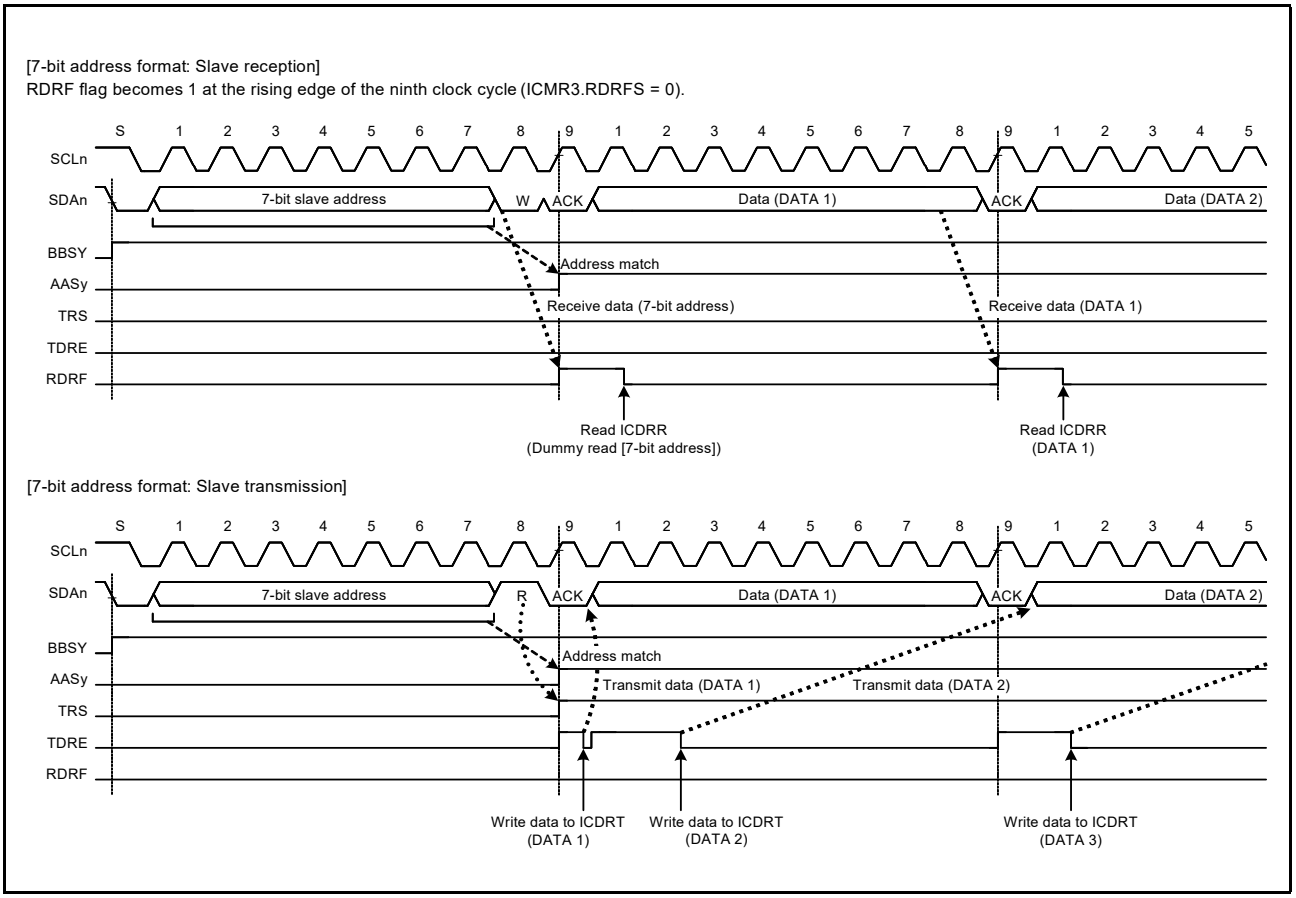

Figure 34.24 AASy Flag Set Timing with 7-Bit Address Format Selected

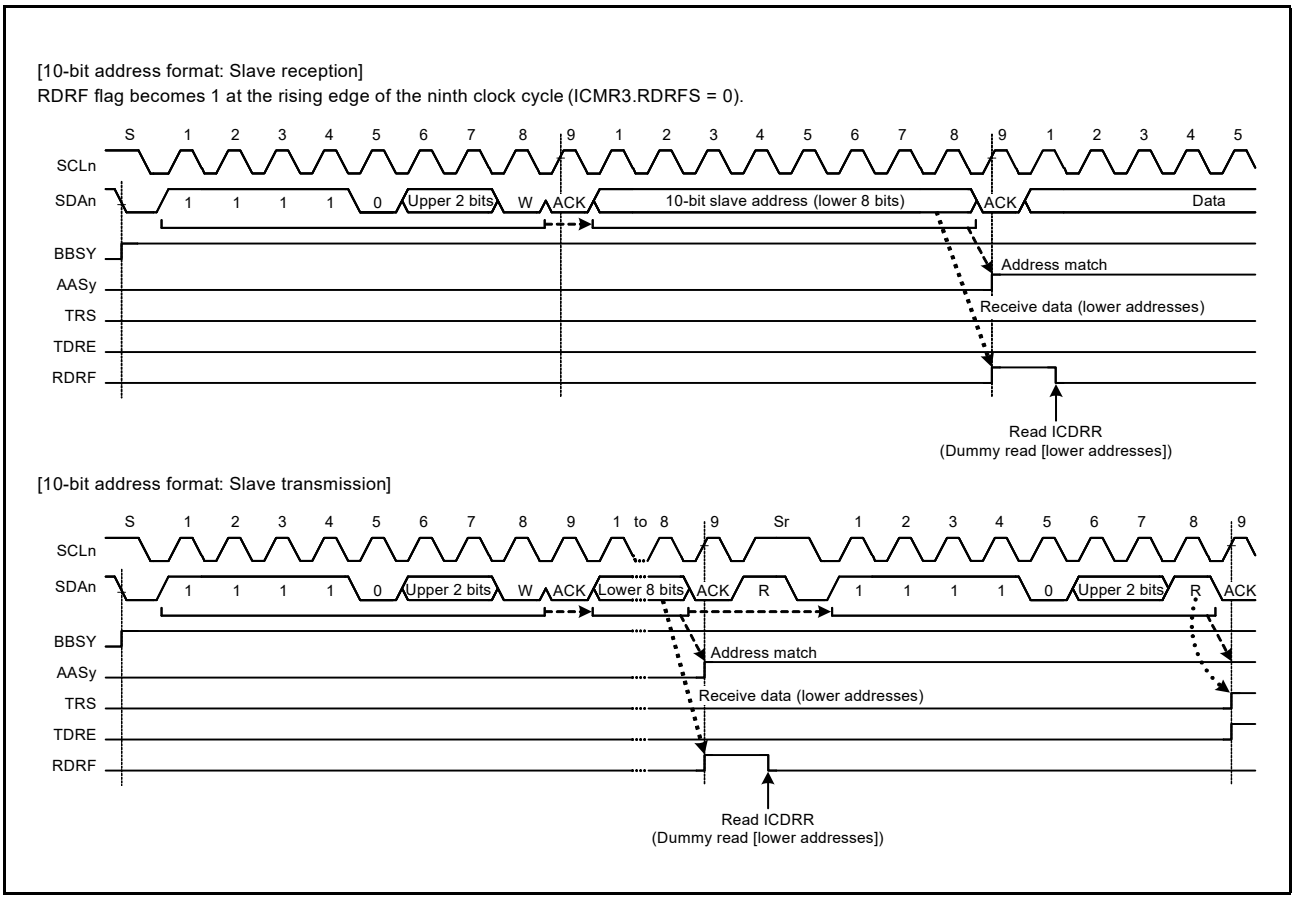

Figure 34.25 AASy Flag Set Timing with 10-Bit Address Format Selected

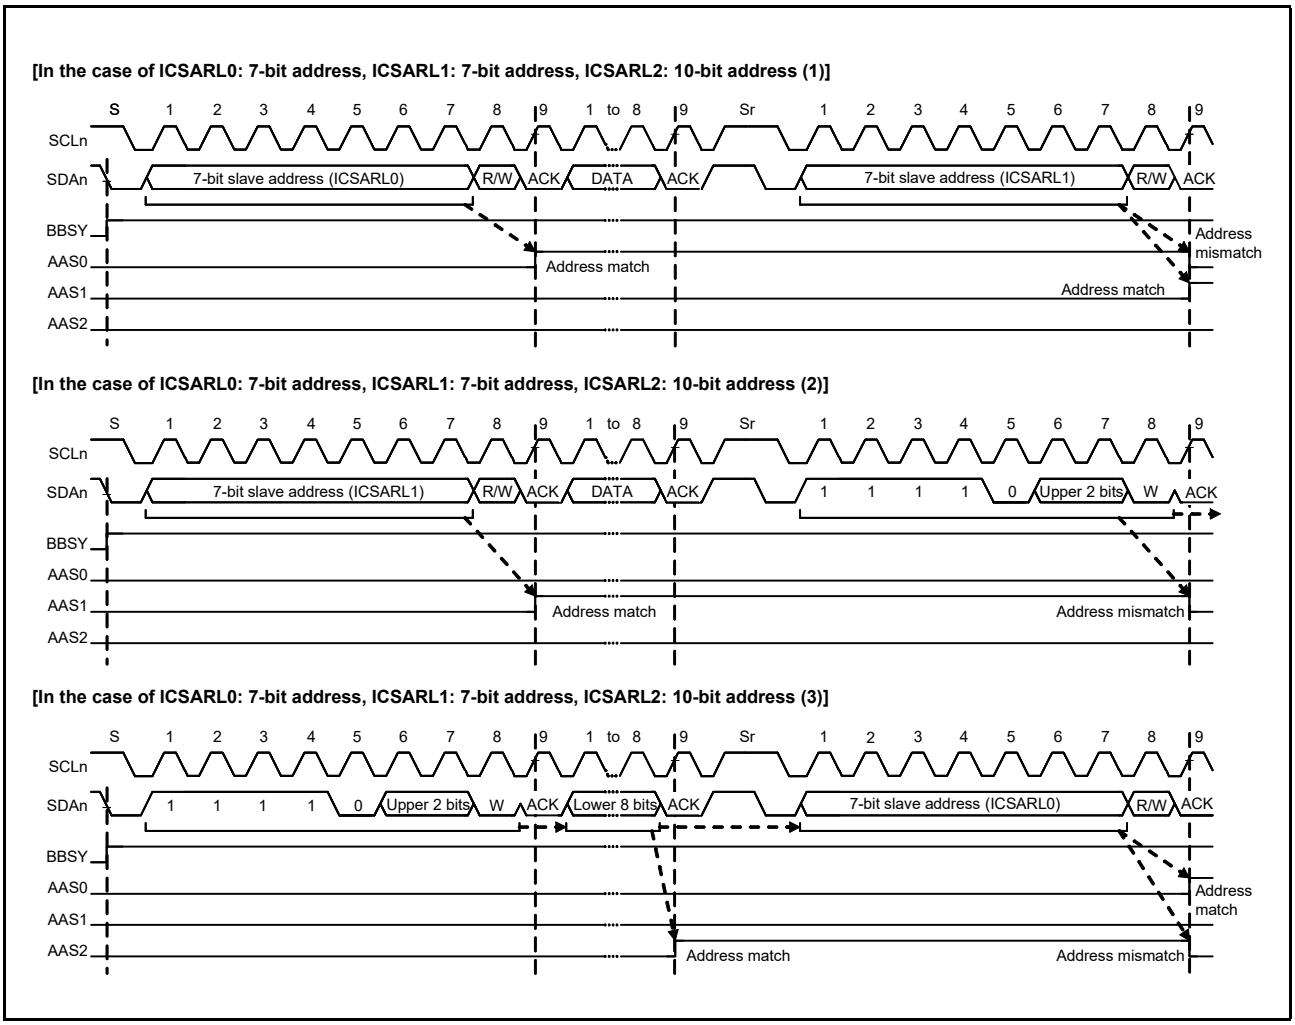

Figure 34.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed

34.7.2 Detection of the General Call Address

The RIIC has a facility for detecting the general call address (0000 000b + 0 [W]). This is enabled by setting the GCAE bit in ICSER to 1.

If the address received after a start or restart condition is issued is 0000 000b + 1[R] (start byte), the RIIC recognizes this as the address of a slave device with an “all-zero” address but not as the general call address.

When the RIIC detects the general call address, both the GCA flag in ICSR1 and the RDRF flag in ICSR2 are set to 1 on the rising edge of the ninth cycle of SCL clock. This leads to the generation of a receive data full interrupt (RXI). The value of the GCA flag can be confirmed to recognize that the general call address has been transmitted.

Operation after detection of the general call address is the same as normal slave receive operation.

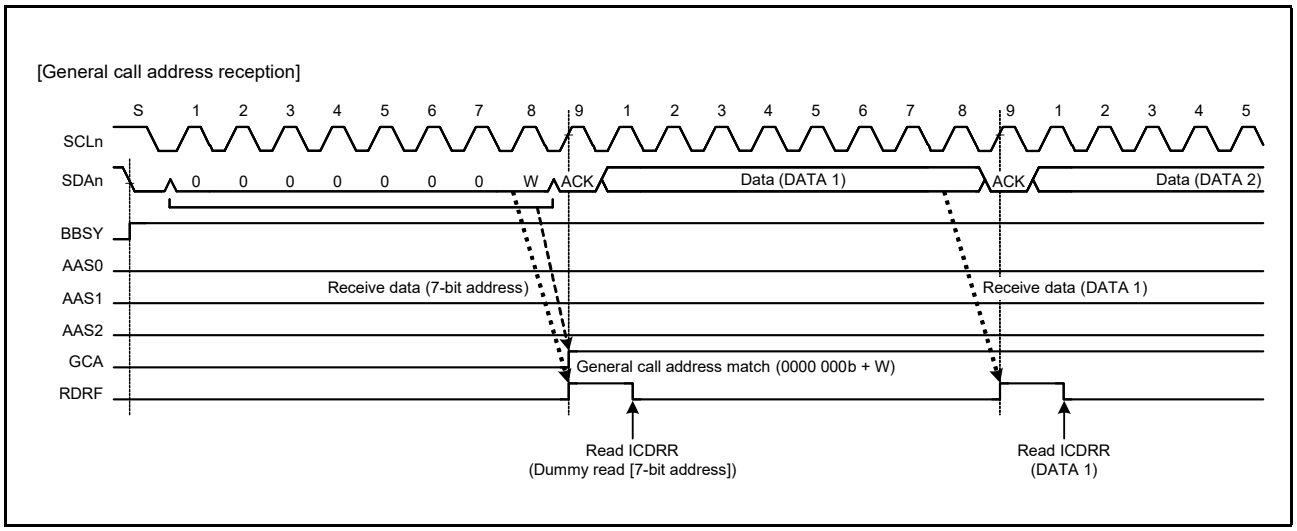

Figure 34.27 Timing of GCA Flag Setting during Reception of General Call Address

34.7.3 Device-ID Address Detection

The RIIC module has a facility for detecting device-ID addresses conforming with the I2C bus specification (Rev. 03). When the RIIC receives 1111 100b as the first byte after a start condition or restart condition was issued with the DIDE bit in ICSER set to 1, the RIIC recognizes the address as a device ID, sets the DID flag in ICSR1 to 1 on the rising edge of the eighth SCL clock cycle when the following R/W# bit is 0, and then compares the second and subsequent bytes with its own slave address. If the address matches the value in the slave address register, the RIIC sets the corresponding AASy flag (y = 0 to 2) in ICSR1 to 1.

After that, when the first byte received after a start or restart condition is issued matches the device ID address (1111 100b) again and the following R/W# bit is 1, the RIIC does not compare the second and subsequent bytes and sets the ICSR2.TDRE flag to 1.

In the device-ID address detection function, the RIIC sets the DID flag to 0 if a match with the RIIC's own slave address is not obtained or a match with the device ID address is not obtained after a match with the RIIC's own slave address and the detection of a restart condition. In this case, if the first byte after detection of a start or restart condition matches the device ID address (1111 100b) and the R/W# bit is 0, the RIIC sets the DID flag to 1 and compares the second and subsequent bytes with the RIIC's slave address. If the R/W# bit is 1, the DID flag holds the previous value and the RIIC does not compare the second and subsequent bytes. Therefore, the reception of a device-ID address can be checked by reading the DID flag after confirming that TDRE = 1.

Furthermore, prepare the device-ID fields (three bytes: 12 bits indicating the manufacturer + 9 bits identifying the part + 3 bits indicating the revision) that must be sent to the host after reception of a continuous device-ID field as normal data for transmission. For details of the information that must be included in device-ID fields, contact NXP Semiconductors.

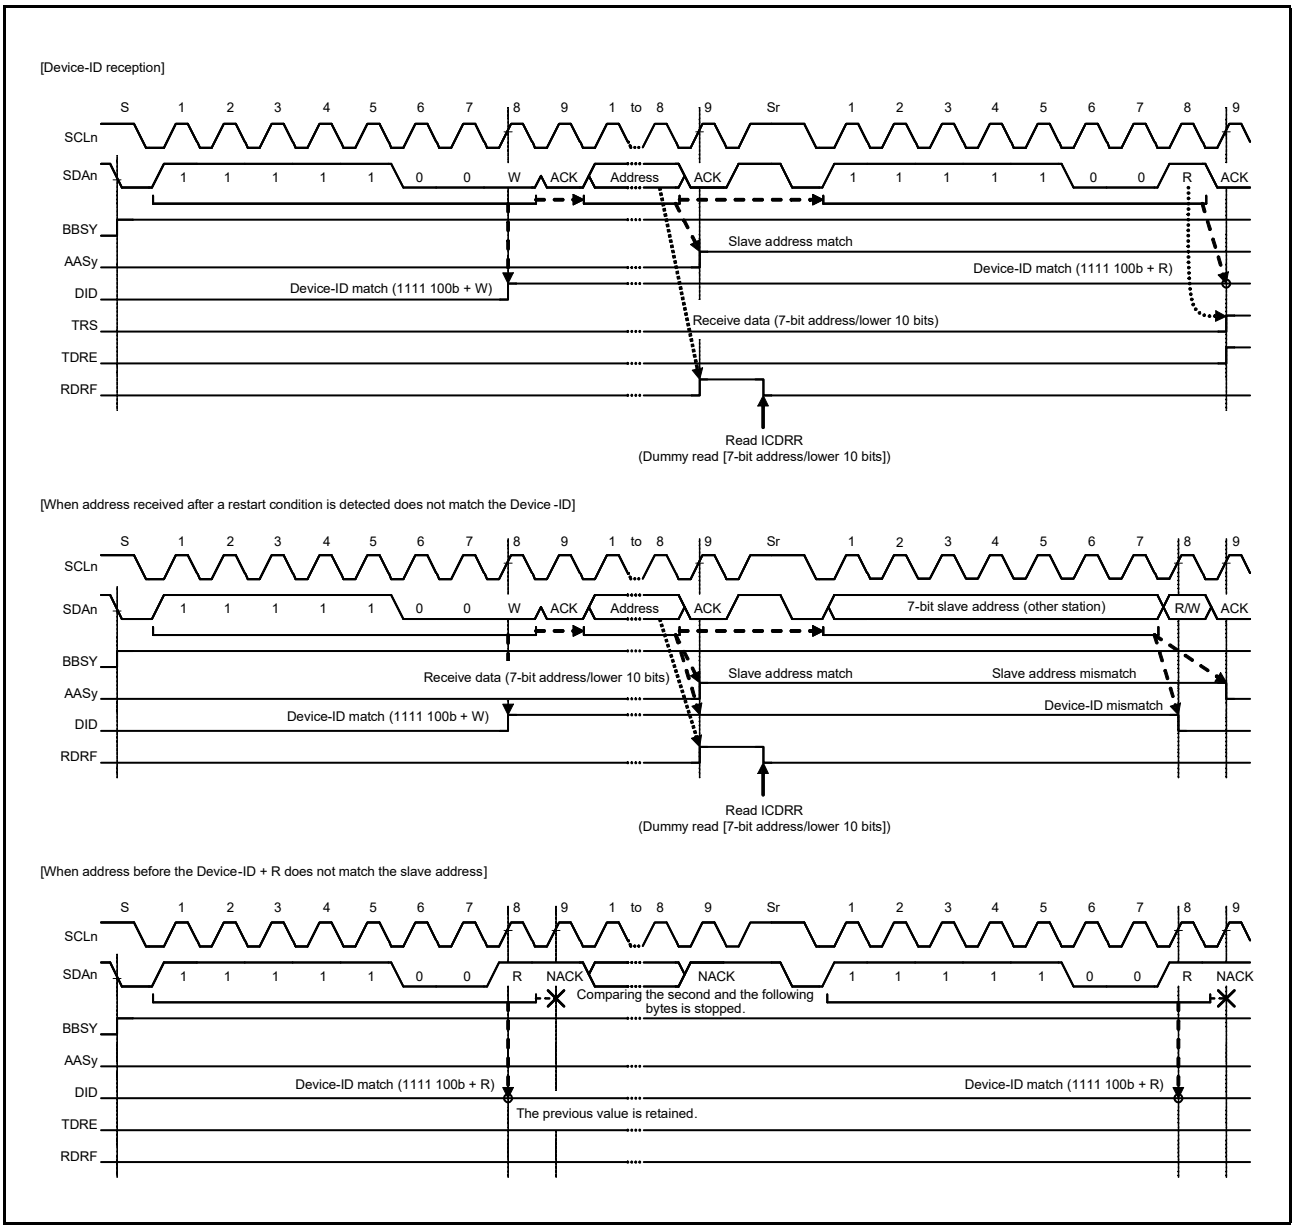

Figure 34.28 AASy/DID Flag Set/Clear Timing during Reception of Device-ID

34.8 Automatic Low-Hold Function for SCL

34.8.1 Function to Prevent Wrong Transmission of Transmit Data

If the shift register (ICDRS) is empty when data have not been written to the I2C bus transmit data register (ICDRT) with the RIIC in transmission mode (TRS bit = 1 in ICCR2), the SCLn line is automatically held at the low level over the intervals shown below. This low-hold period is extended until data for transmission have been written, which prevents the unintended transmission of erroneous data.

Master transmission mode

- Low-level interval after a start condition or restart condition is issued
- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

Slave transmission mode

- Low-level interval between the ninth clock cycle of one transfer and the first clock cycle of the next

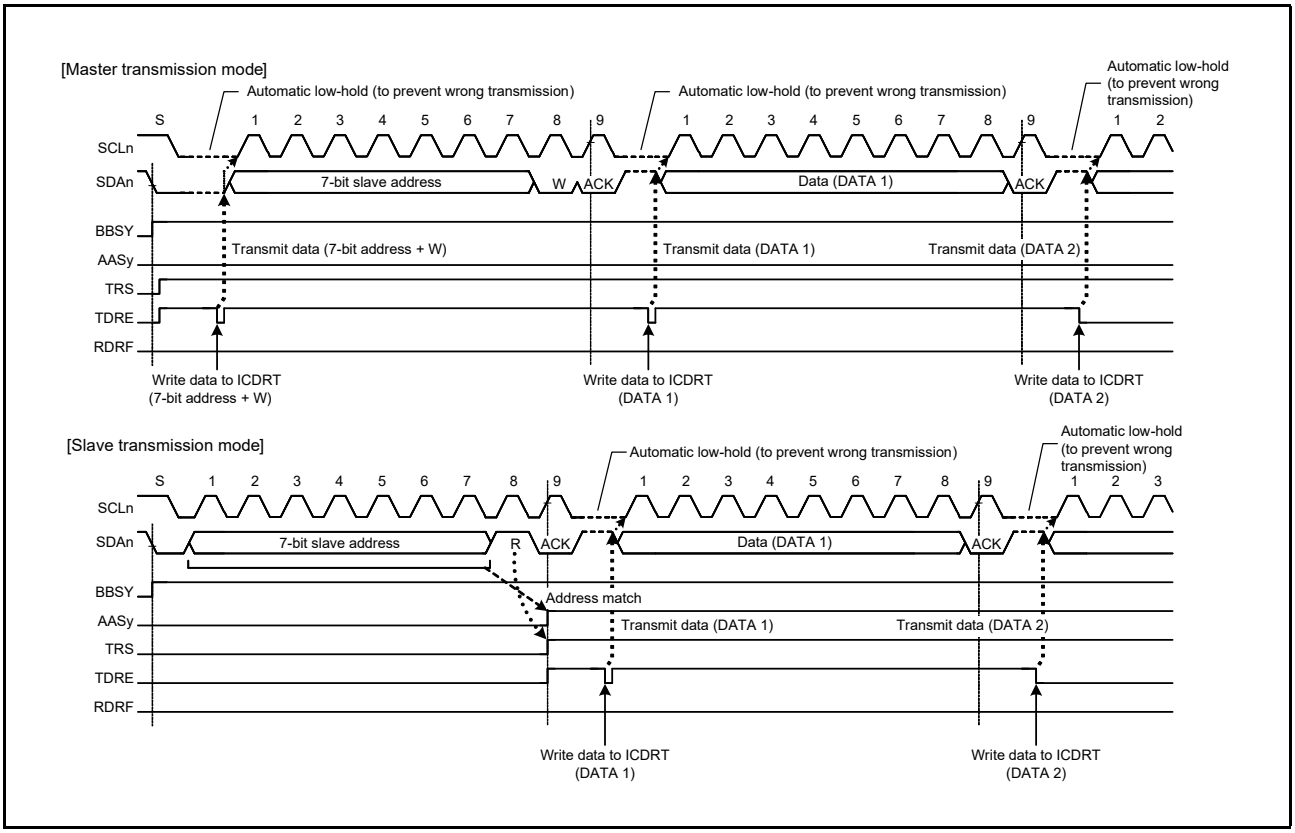

Figure 34.29 Automatic Low-Hold Operation in Transmission Mode

34.8.2 NACK Reception Transfer Suspension Function

The RIIC has a function to suspend transfer operation when NACK is received in transmission mode (TRS bit = 1 in ICCR2). This function is enabled when the NACKE bit in ICFER is set to 1 (transfer suspension enabled). If the next transmit data has already been written (TDRE flag = 0 in ICSR2) when NACK is received, next data transmission at the falling edge of the ninth SCL clock cycle is automatically suspended. This prevents the SDAn line output level from being held low when the MSB of the next transmit data is 0.

If the transfer operation is suspended by this function (NACKF flag = 1 in ICSR2), transmit operation and receive operation are discontinued. To restore transmit/receive operation, be sure to set the NACKF flag to 0. In master transmission mode, set the NACKF flag to 0, issue a restart or stop condition, and then issue a start condition again.

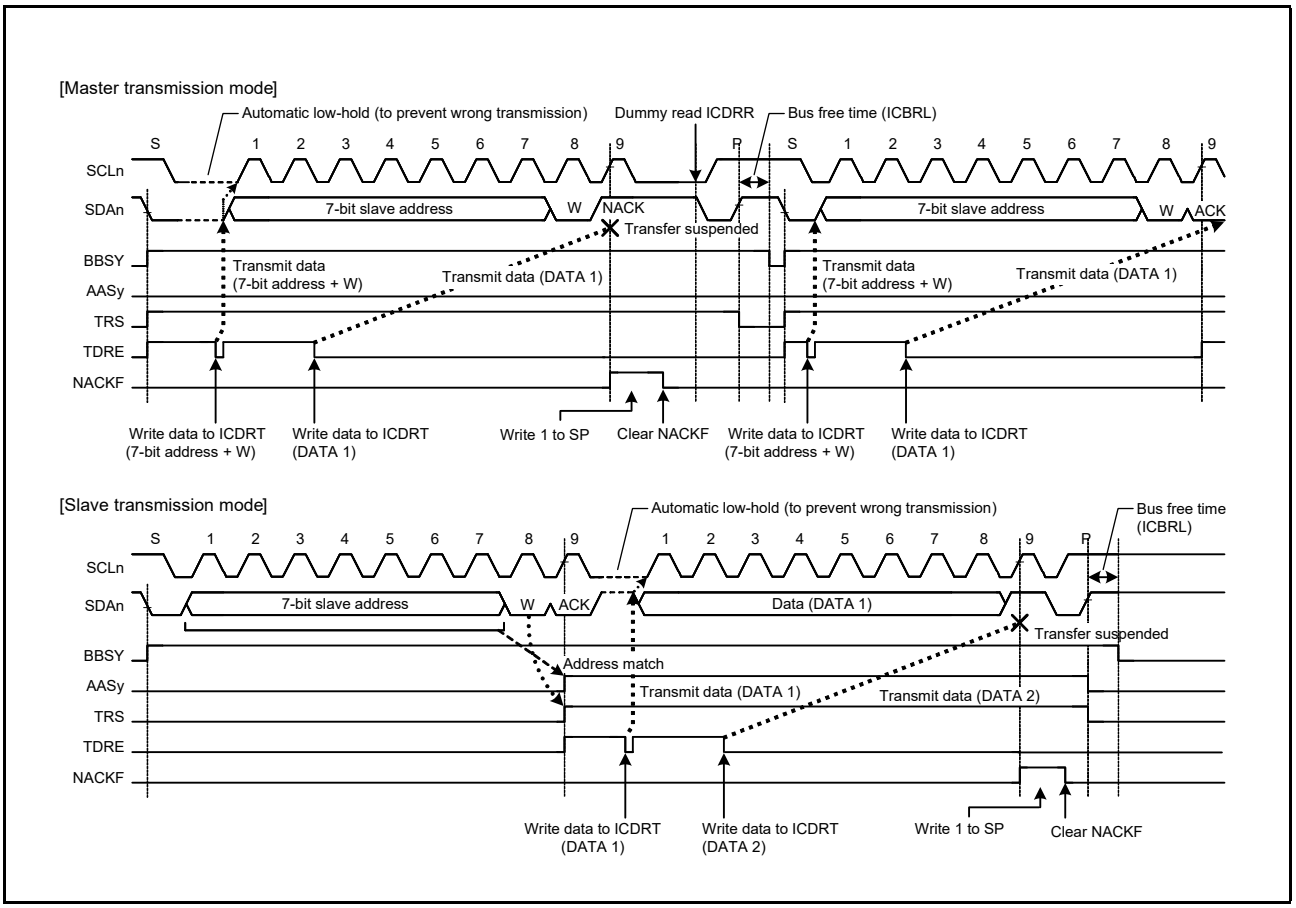

Figure 34.30 Suspension of Data Transfer When NACK is Received (NACKE = 1)

34.8.3 Function to Prevent Failure to Receive Data

If response processing is delayed when receive data (ICDRR) read is delayed for a period of one transfer frame or more with receive data full (RDRF flag = 1 in ICSR2) in reception mode (TRS = 0 in ICCR2), the RIIC holds the SCLn line low automatically immediately before the next data is received to prevent failure to receive data.
This function to prevent failure to receive data using the automatic low-hold function is also enabled even if the read processing of the final receive data is delayed and, in the meantime, the RIIC's own slave address is designated after a stop condition is issued. This function does not disturb other communication because the RIIC does not hold the SCLn line low when a mismatch with its own slave address occurs after a stop condition is issued.
Sections in which the SCLn line is held low can be selected with a combination of the WAIT and RDRFS bits in ICMR3.

(1) 1-Byte Receive Operation and Automatic Low-Hold Function Using the WAIT Bit

When the WAIT bit in ICMR3 is set to 1, the RIIC performs 1-byte receive operation using the WAIT bit function. When the ICMR3.RDRFS bit is 0, the ACKBT bit value in ICMR3 is automatically sent to the acknowledge bit in the period from the falling edge of the eighth SCL clock cycle to the falling edge of the ninth SCL clock cycle. When the falling edge of the ninth SCL clock cycle is detected, the SCLn line is automatically held low by the WAIT bit function. This low-hold is released by reading data from ICDRR, which enables bytewise receive operation.
The WAIT bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master reception mode or slave reception mode.

(2) 1-Byte Receive Operation (ACK/NACK Transmission Control) and Automatic Low-Hold Function Using the RDRFS Bit

When the RDRFS bit in ICMR3 is set to 1, the RIIC performs 1-byte receive operation using the RDRFS bit function. When the RDRFS bit is set to 1, the RDRF flag (receive data full) in ICSR2 is set to 1 at the rising edge of the eighth SCL clock cycle, and the SCLn line is automatically held low at the falling edge of the eighth SCL clock cycle. This low-hold is released by writing a value to the ACKBT bit in ICMR3, but cannot be released by reading data from ICDRR, which enables receive operation by the ACK/NACK transmission control according to the data received in byte units.
The RDRFS bit function is enabled for receive frames after a match with the RIIC's own slave address (including the general call address and host address) is obtained in master reception mode or slave reception mode.

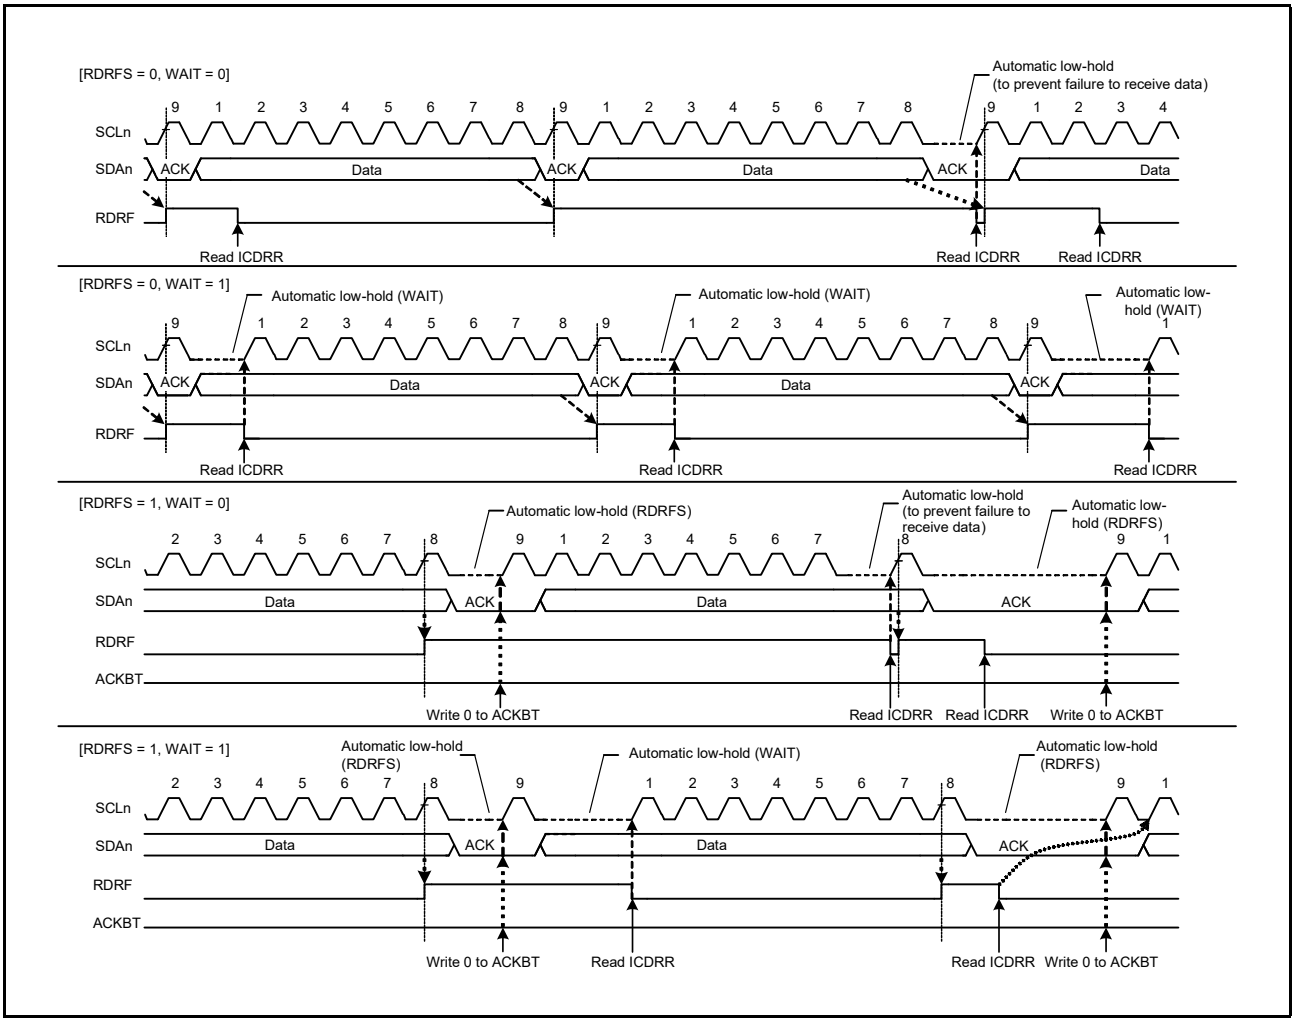

Figure 34.31 Automatic Low-Hold Operation in Reception Mode (Using RDRFS and WAIT Bits)

34.9 Arbitration-Lost Detection Functions

In addition to the normal arbitration-lost detection function defined by the I2C bus standard, the RIIC has functions to prevent double-issue of a start condition, to detect arbitration-lost during transmission of NACK, and to detect arbitration-lost in slave transmission mode.

34.9.1 Master Arbitration-Lost Detection (MALE Bit)

The RIIC drives the SDAn line low to issue a start condition. However, if the SDAn line has already been driven low by another master device issuing a start condition, the RIIC regards its own issuing of a start condition as an error and considers this a loss in arbitration, so priority is given to transfer by the other master device. Similarly, if a request to issue a start condition is made by setting the ST bit in ICCR2 to 1 while the bus is busy (BBSY flag = 1 in ICCR2), the RIIC regards this as a double-issuing-of-start-condition error and considers itself to have lost in arbitration, thus preventing a failure of transfer due to issuing of a start condition while transfer is in progress.
When a start condition is issued successfully, the data for transmission including the address bits (i.e. the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state, and the low level is detected on the SDAn line), the RIIC loses in arbitration.
After a loss in arbitration of mastership, the RIIC immediately enters slave reception mode. If a slave address (including the general call address) matches its own address at this time, the RIIC continues in slave operation.
A loss in arbitration of mastership is detected when the following conditions are met while the MALE bit in ICFER is 1 (master arbitration-lost detection enabled).
[Master arbitration-lost conditions]

- Non-matching of the internal level for output on SDA and the level on the SDAn line after a start condition was issued by setting the ST bit in ICCR2 to 1 while the BBSY flag in ICCR2 was set to 0 (erroneous issuing of a start condition)
- Setting of the ST bit in ICCR2 to 1 (start condition double-issue error) while the BBSY flag in ICCR2 is set to 1
- When the transmit data excluding acknowledge (internal SDA output level) does not match the level on the SDAn line in master transmission mode (MST and TRS bits = 11b in ICCR2)

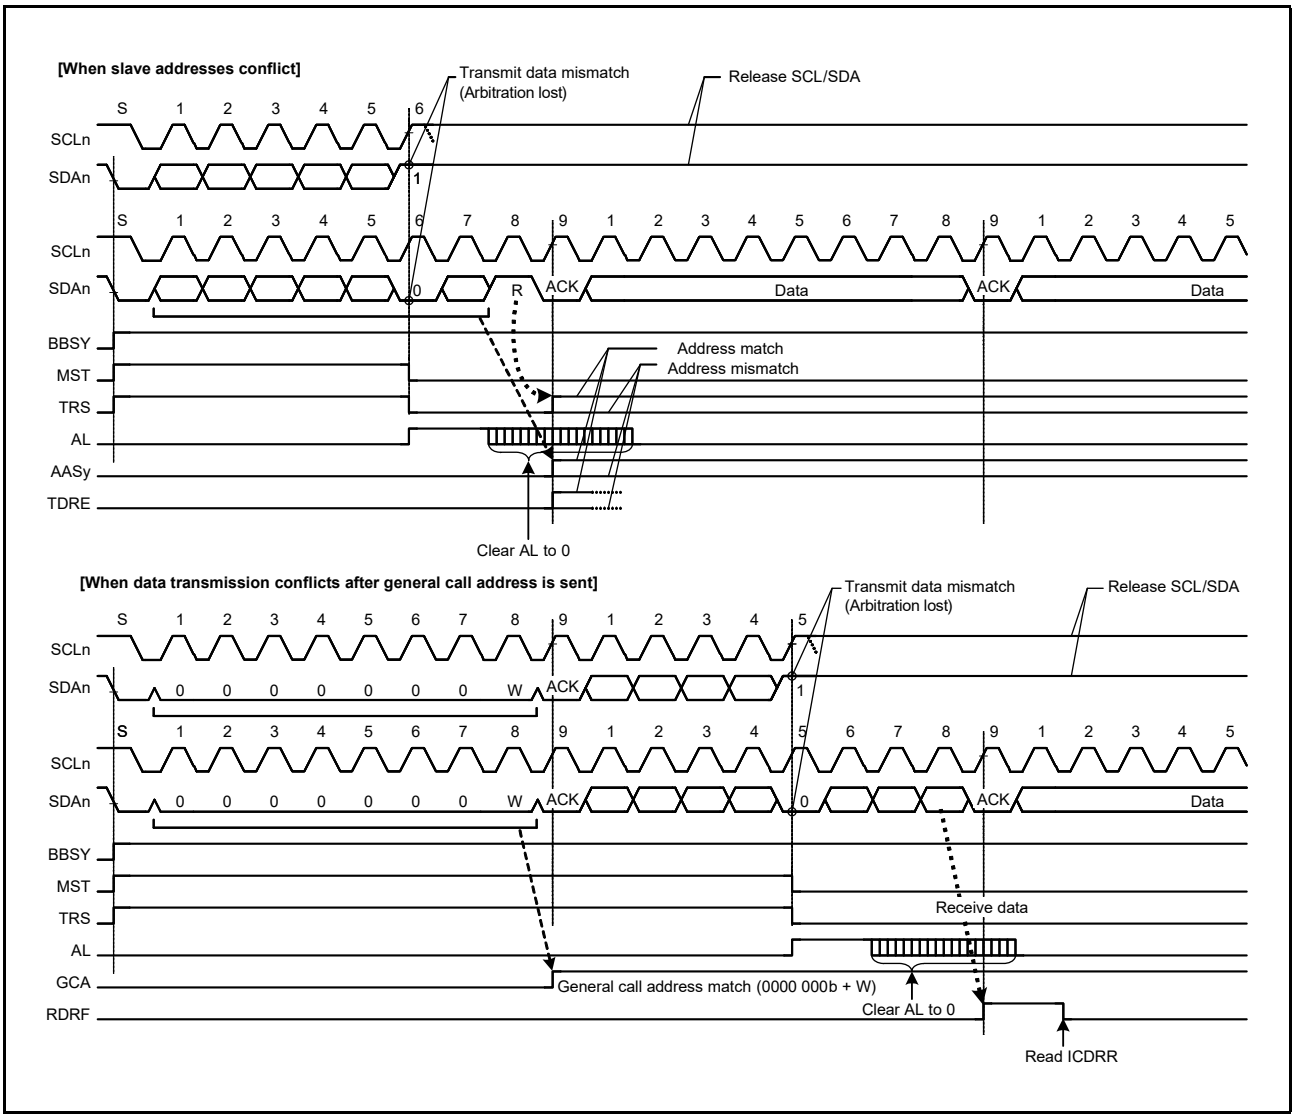

Figure 34.32 Examples of Master Arbitration-Lost Detection (MALE = 1)

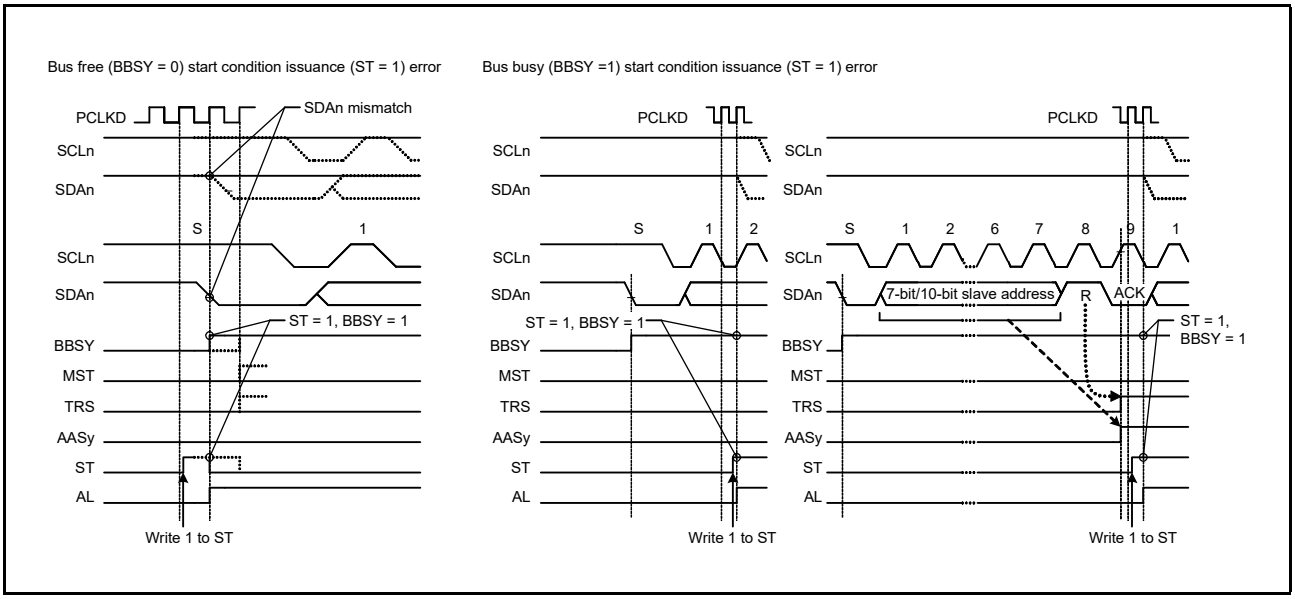

Figure 34.33 Arbitration-Lost When a Start Condition is Issued (MALE = 1)

34.9.2 Function to Detect Loss of Arbitration during NACK Transmission (NALE Bit)

The RIIC has a function to cause arbitration to be lost if the internal SDA output level does not match the level on the SDAn line (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state, and the low level is detected on the SDAn line) during transmission of NACK in reception mode. Arbitration is lost due to a conflict of NACK transmission and ACK transmission when two or more master devices receive data from the same slave device simultaneously in a multi-master system. Such conflict occurs when multiple master devices send/receive the same information through a single slave device. Figure 34.34 shows an example of arbitration-lost detection during transmission of NACK.

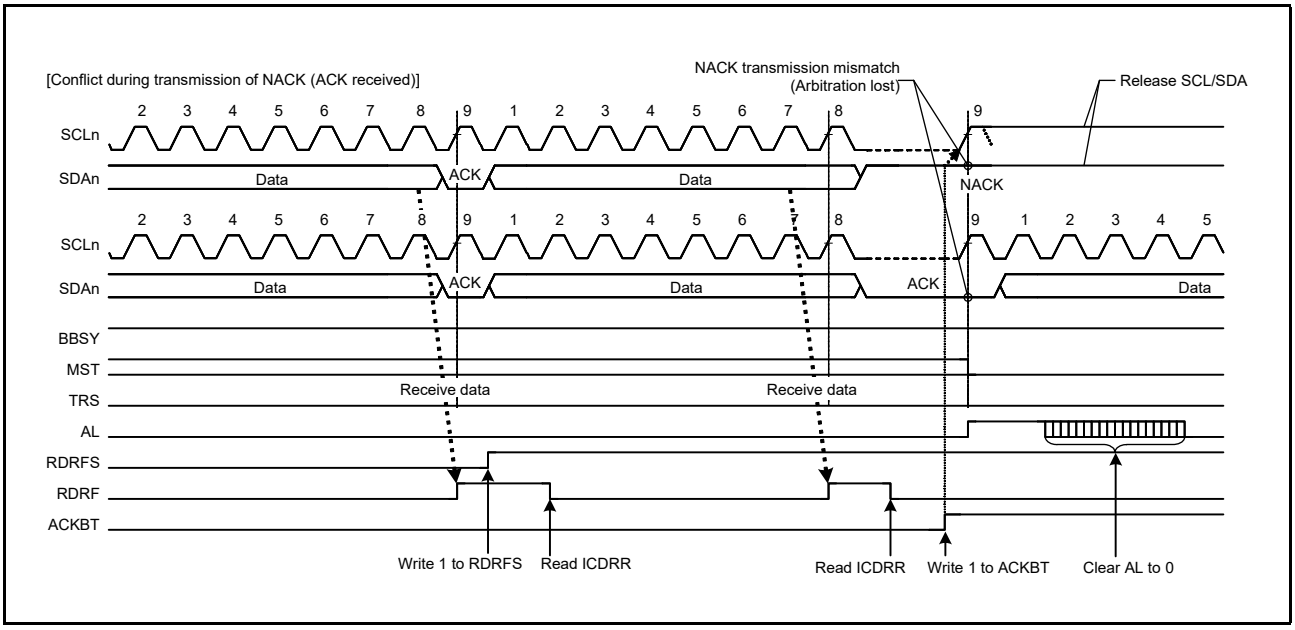

Figure 34.34 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1)

The following explains arbitration-lost detection using an example where two master devices (master A and master B) and a single slave device are connected through the bus. In this example, master A receives two bytes of data from the slave device, and master B receives four bytes of data from the slave device.

If master A and master B access the slave device simultaneously, because the slave address is identical, arbitration is not lost in both master A and master B during access to the slave device. Therefore, both master A and master B recognize that they have obtained the bus mastership and operate as such. Here, master A sends NACK when it has received two final bytes of data from the slave device. Meanwhile, master B sends ACK because it has not received necessary four bytes of data. At this time, the NACK transmission from master A and the ACK transmission from master B conflict. In general, if a conflict like this occurs, master A cannot detect ACK transmitted by master B and issues a stop condition. Therefore, the issuance of the stop condition conflicts with the SCL clock output of master B, which disturbs communication.

When the RIIC receives ACK during transmission of NACK, it detects a defeat in conflict with other master devices and causes arbitration to be lost.

If arbitration is lost during transmission of NACK, the RIIC immediately cancels the slave match condition and enters slave reception mode. This prevents a stop condition from being issued, preventing a communication failure on the bus.

The RIIC detects arbitration-lost during transmission of NACK when the following condition is met with the NALE bit in ICFER set to 1 (arbitration-lost detection during NACK transmission enabled).

[Condition for arbitration-lost during NACK transmission]

- When the internal SDA output level does not match the SDAn line (ACK is received) during transmission of NACK (ACKBT bit = 1 in ICMR3)

34.9.3 Slave Arbitration-Lost Detection (SALE Bit)

The RIIC has a function to cause arbitration to be lost if the data for transmission (i.e. the internal SDA output level) and the level on the SDAn line do not match (the high output as the internal SDA output; i.e. the SDAn pin is in the high-impedance state, and the low level is detected on the SDAn line) in slave transmission mode.
When it loses slave arbitration, the RIIC is immediately released from the slave-matched state and enters slave reception mode.
The RIIC detects slave arbitration-lost when the following condition is met with the SALE bit in ICFER set to 1 (slave arbitration-lost detection enabled).

[Condition for slave arbitration-lost]

- When transmit data excluding acknowledge (internal SDA output level) does not match the SDAn line in slave transmission mode (MST and TRS bits = 01b in ICCR2)

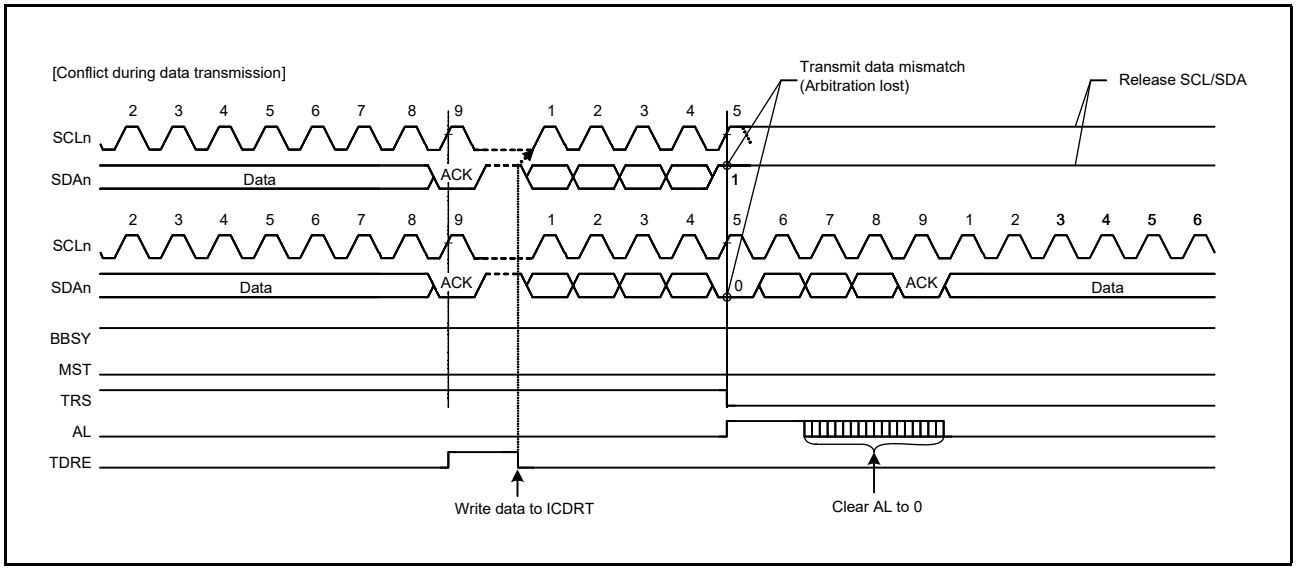

Figure 34.35 Example of Slave Arbitration-Lost Detection (SALE = 1)

34.10 Start Condition/Restart Condition/Stop Condition Issuing Function

34.10.1 Issuing a Start Condition

The RIIC issues a start condition when the ST bit in ICCR2 is set to 1.
When the ST bit is set to 1, a start condition issuance request is made and the RIIC issues a start condition when the BBSY flag in ICCR2 is 0 (bus free state). When a start condition is issued normally, the RIIC automatically shifts to the master transmission mode.
A start condition is issued in the following sequence.

[Start condition issuance]
(1) Drive the SDAn line low (high level to low level).
(2) Ensure the start condition hold time set in ICBRH.
(3) Drive the SCLn line low (high level to low level).
(4) Detect low level of the SCLn line and ensure the low-level period of SCLn line set in ICBRL.

34.10.2 Issuing a Restart Condition

The RIIC issues a restart condition when the RS bit in ICCR2 is set to 1.
When the RS bit is set to 1, a restart condition issuance request is made and the RIIC issues a restart condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).
A restart condition is issued in the following sequence.

[Restart condition issuance]
(1) Release the SDAn line.
(2) Ensure the low-level period of SCLn line set in ICBRL.
(3) Release the SCLn line (low level to high level).
(4) Detect a high level of the SCLn line and ensure the restart condition setup time set in ICBRL.
(5) Drive the SDAn line low (high level to low level).
(6) Ensure the restart condition hold time set in ICBRH.
(7) Drive the SCLn line low (high level to low level).
(8) Detect a low level of the SCLn line and ensure the low-level period of SCLn line set in ICBRL.

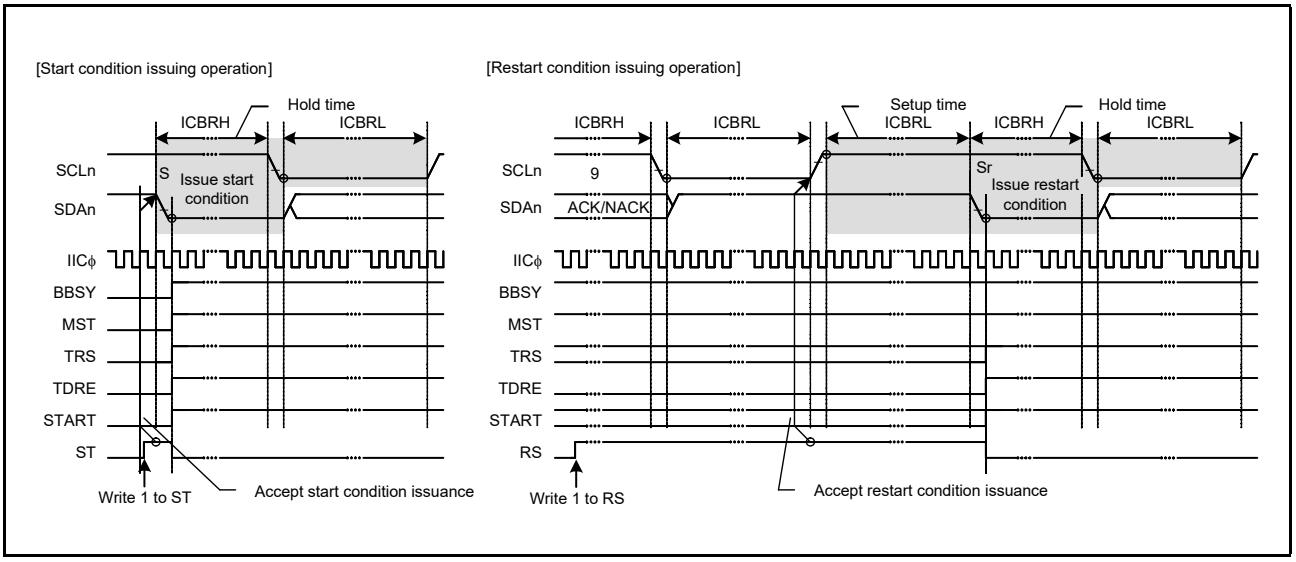

Figure 34.36 Start Condition/Restart Condition Issue Timing (ST and RS Bits)

34.10.3 Issuing a Stop Condition

The RIIC issues a stop condition when the SP bit in ICCR2 is set to 1.
When the SP bit is set to 1, a stop condition issuance request is made and the RIIC issues a stop condition when the BBSY flag in ICCR2 is 1 (bus busy state) and the MST bit in ICCR2 is 1 (master mode).
A stop condition is issued in the following sequence.

[Stop condition issuance]

- Drive the SDAn line low (high level to low level).
- Ensure the low-level period of SCLn line set in ICBRL.
- Release the SCLn line (low level to high level).
- Detect a high level of the SCLn line and ensure the stop condition setup time set in ICBRH.
- Release the SDAn line (low level to high level).
- Ensure the bus free time set in ICBRL.
- Clear the BBSY flag to 0 (to release the bus mastership).

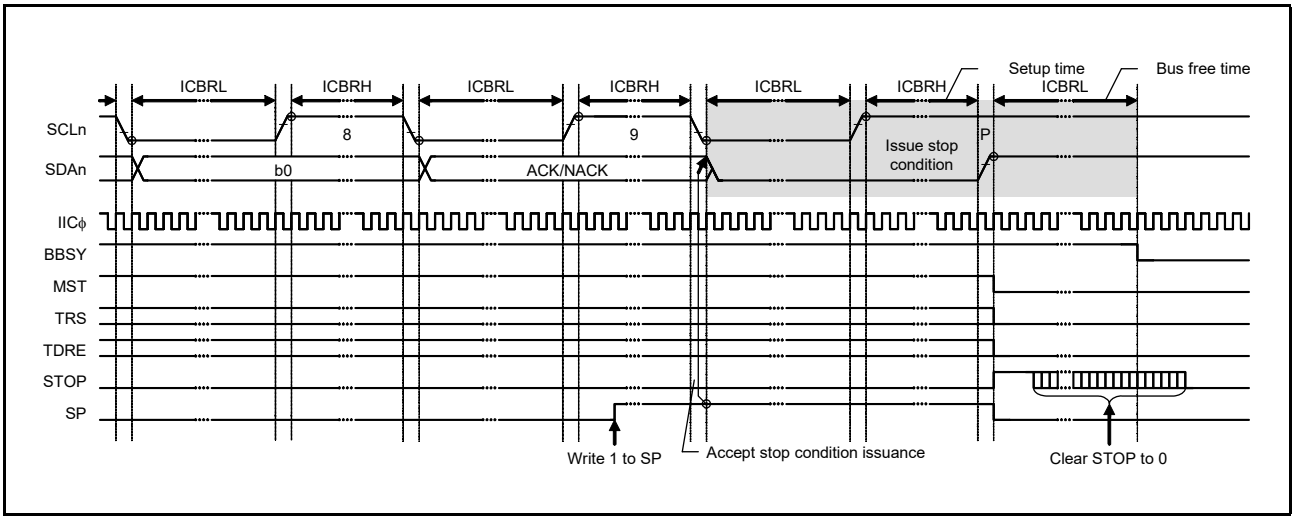

Figure 34.37 Stop Condition Issue Timing (SP Bit)

34.11 Bus Hanging

If the clock signals from the master and slave devices go out of synchronization due to noise or other factors, the I²C bus might hang with a fixed level on the SCLn line and/or SDAn line.
As measures against the bus hanging, the RIIC has a timeout function to detect hanging by monitoring the SCLn line, a function for the output of an extra SCL clock cycle to release the bus from a hung state due to clock signals being out of synchronization, the RIIC reset function, and internal reset function.
By checking the SCLO, SDAO, SCLI, and SDAI bits in ICCR1, it is possible to see whether the RIIC or its partner in communications is placing the low level on the SCLn or SDAn line.

34.11.1 Timeout Function

The RIIC includes a timeout function for detecting when the SCLn line has been stuck longer than the predetermined time. The RIIC can detect an abnormal bus state by monitoring that the SCLn line is stuck low or high for a predetermined time.
The timeout function monitors the SCLn line state and counts the low-level period or high-level period using the internal counter. The timeout function resets the internal counter each time the SCLn line changes (rising or falling), but continues to count unless the SCLn line changes. If the internal counter overflows due to no SCLn line change, the RIIC can detect the timeout and report the bus hung state.
This timeout function is enabled when the ICFER.TMOE bit is 1. It detects a hung state that the SCLn line is stuck low or high during the following conditions:

- The bus is busy (ICCR2.BBSY flag is 1) in master mode (ICCR2.MST bit is 1).
- The RIIC's own slave address is detected (ICSR1 register is not 00h) and the bus is busy (ICCR2.BBSY flag is 1) in slave mode (ICCR2.MST bit is 0).
- The bus is free (ICCR2.BBSY flag is 0) while generation of a start condition is requested (ICCR2.ST bit is 1).

The internal counter of the timeout function works using the internal reference clock (IICϕ) set by the CKS[2:0] bits in ICMR1 as a count source. It functions as a 16-bit counter when long mode is selected (TMOS bit = 0 in ICMR2) or a 14-bit counter when short mode is selected (TMOS bit = 1).
The SCLn line level (low/high or both levels) during which this counter is activated can be selected by the setting of the TMOH and TMOL bits in ICMR2. If both TMOL and TMOH bits are set to 0, the internal counter does not work.

Note: When the timeout function for detecting is to be used, see section 34.2.4, I²C Bus Mode Register 2 (ICMR2), section 34.3, Operation, and section 34.3.2, Initial Settings.

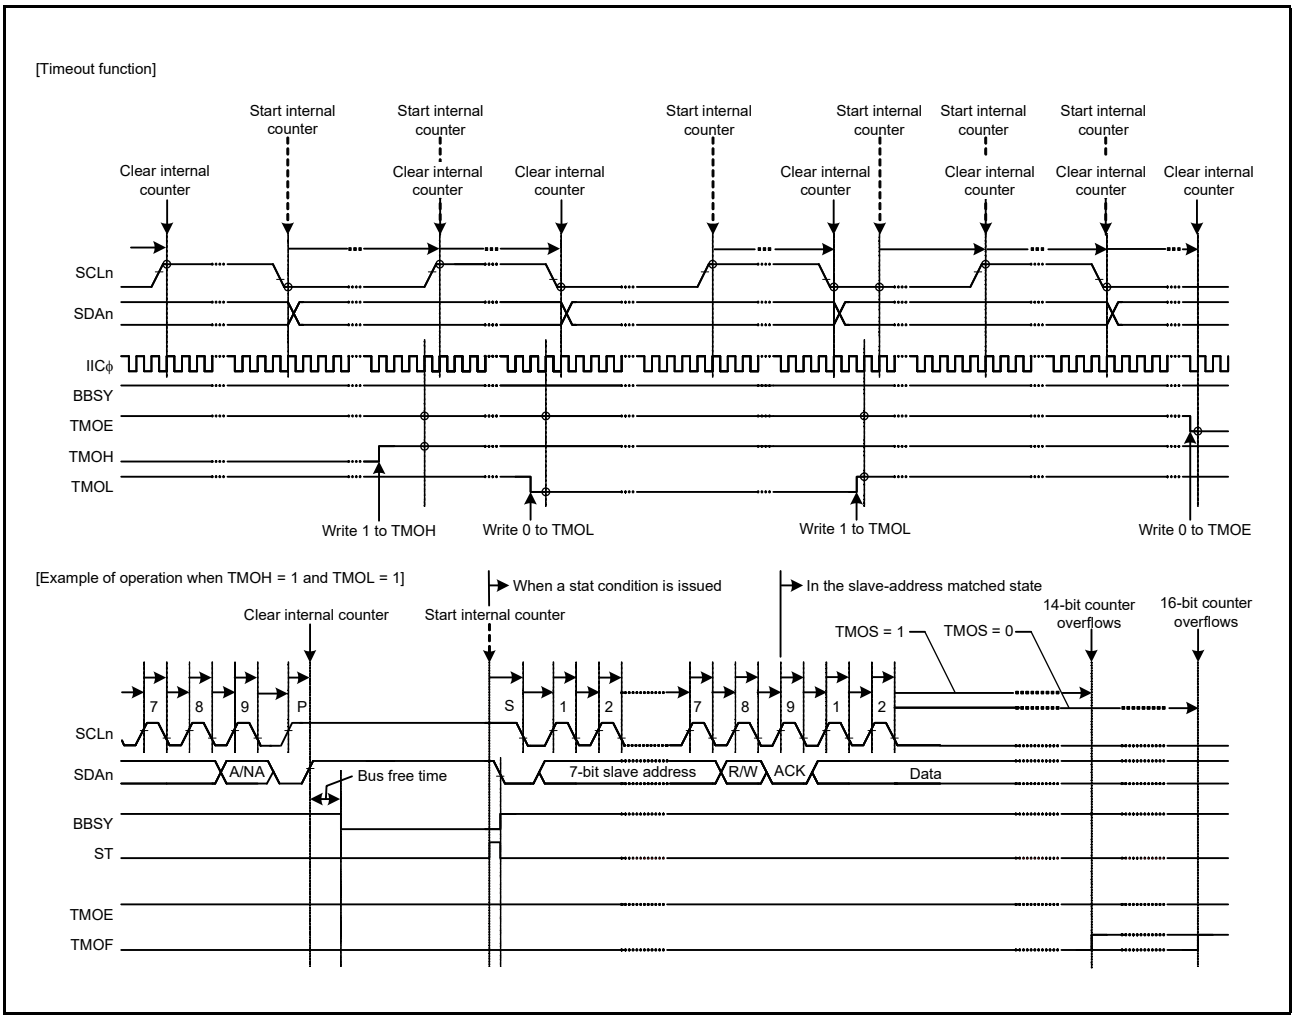

Figure 34.38 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits)

34.11.2 Extra SCL Clock Cycle Output Function

In master mode, the RIIC module has a facility for the output of extra SCL clock cycles to release the SDAn line of the slave device from being held at the low level due to the master being out of synchronization with the slave device.
This function is mainly used in master mode to release the SDAn line of the slave device from the state of being fixed to the low level by including extra cycles of SCL output from the RIIC with single cycles of the SCL clock as the unit in the case of a bus error where the RIIC cannot issue a stop condition because the slave device is holding the SDAn line at the low level. Do not use this facility in normal situations. Using it when communications are proceeding correctly will lead to malfunctions.
When the CLO bit in ICCR1 is set to 1 in master mode, a single cycle of the SCL clock at the frequency corresponding to the transfer rate settings (settings of the CKS[2:0] bits in ICMR1, and of the ICBRH and ICBRL registers) is output as an extra clock cycle. After output of this single cycle of the SCL clock, the CLO bit is automatically set to 0. Therefore, further extra clock cycles can be output consecutively by the software program writing 1 to the CLO bit after having read CLO = 0.
When the RIIC module is in master mode and the slave device is holding the SDAn line at the low level because synchronization with the slave device has been lost due to the effects of noise, etc., the output of a stop condition is not possible. The facility for output of an extra cycle of the SCL clock can be used to output extra cycles of SCL one by one to make the slave device release the SDAn line from being held at the low level, thus recovering the bus from an unusable state. Release of the SDAn line by the slave device can be monitored by reading the SDAI bit in ICCR1. After confirming release of the SDAn line by the slave device, complete communications by reissuing the stop condition.
Use this facility with the MALE bit (master arbitration-lost detection disabled) in ICFER set to 0. If the MALE bit is set to 1 (master arbitration-lost detection enabled), arbitration is lost when the value of the SDAO bit in ICCR1 does not match the state of the SDAn line, so take care on this point.

[Output conditions for using the CLO bit in ICCR1]

- When the bus is free (BBSY flag in ICCR2 = 0) or in master mode (MST bit = 1 and BBSY flag = 1 in ICCR2)
- When the communication device does not hold the SCLn line low

Figure 34.39 shows the operation timing of the extra SCL clock cycle output function (CLO bit).

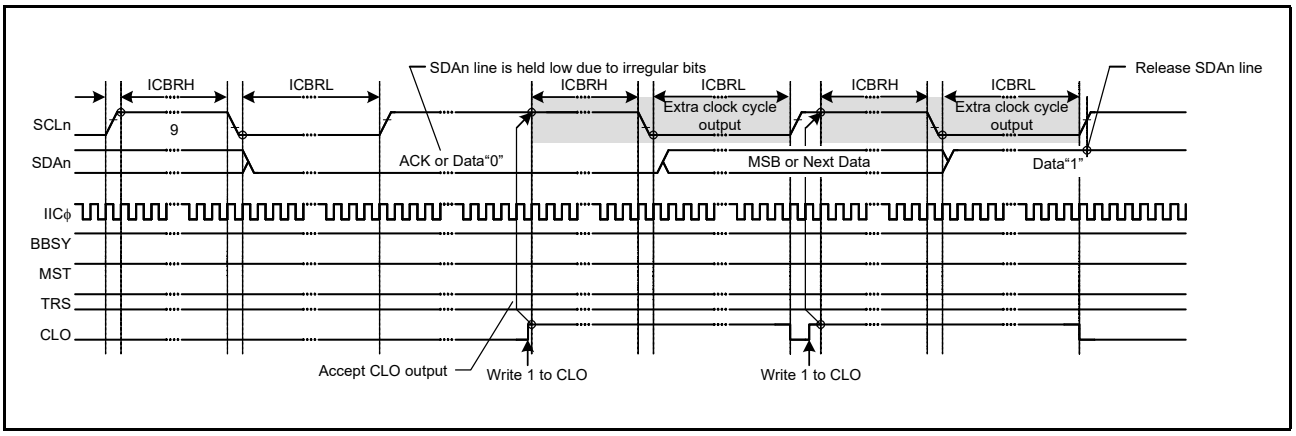

Figure 34.39 Extra SCL Clock Cycle Output Function (CLO Bit)

34.11.3 RIIC Reset and Internal Reset

The RIIC module incorporates a function for resetting itself. There are two types of reset. One is referred to as an RIIC reset; this initializes all registers including the BBSY flag in ICCR2. The other is referred to as an internal reset; this releases the RIIC from the slave-address matched state and initializes the internal counter while retaining other settings. After issuing a reset, be sure to set the IICRST bit in ICCR1 to 0.

Both types of reset are effective for release from bus-hung states since both restore the output state of the SCLn and SDAn pins to the high impedance state.

Do not issue a reset during slave operation because it may lead to a loss of synchronization between the master device clock and the slave device clock. Note that monitoring of the bus state, such as for the presence of a start condition, is not possible during an RIIC reset (ICE and IICRST bits = 01b in ICCR1).

For a detailed description of the RIIC and internal resets, refer to section 34.13, Resets and Register and Function States When Issuing Each Condition.

34.12 Interrupt Sources

The RIIC issues four types of interrupt request: transfer error or event generation (arbitration-lost, NACK detection, timeout detection, start condition detection, and stop condition detection), receive data full, transmit data empty, and transmit end.

Table 34.6 lists details of the several interrupt requests. The receive data full and transmit data empty are both capable of activating data transfer by the DMAC.

Table 34.6 Interrupt Sources

Symbol	Interrupt Source	Interrupt Flag	DMAC Activation	Interrupt Condition
EEI	Transfer error/ event generation	AL	Not possible	AL = 1 • ALIE = 1
		NACKF		NACKF = 1 • NAKIE = 1
		TMOF		TMOF = 1 • TMOIE = 1
		START		START = 1 • STIE = 1
		STOP		STOP = 1 • SPIE = 1
RXI*1	Receive data full	—	Possible	RDRF = 1 • RIE = 1
TXI*2	Transmit data empty	—	Possible	TDRE = 1 • TIE = 1
TEI*3	Transmit end	TEND	Not possible	TEND = 1 • TEIE = 1

Note: There is a delay time between the execution of a write instruction for a peripheral module by the CPU and actual writing to the module. Thus, when an interrupt flag has been cleared or masked, read the relevant flag again to check whether clearing or masking has been completed, and then return from interrupt handling. Returning from interrupt handling without checking that writing to the module has been completed creates a possibility of repeated processing of the same interrupt.

Note 1. The RDRF flag in ICSR2 (a condition for RXI) is automatically set to 0 when data are read from ICDRR.

Note 2. The TDRE flag in ICSR2 (a condition for TXI) is automatically set to 0 when data for transmission are written to ICDRT or a stop condition is detected (STOP flag = 1 in ICSR2).

Note 3. When using the TEI interrupt, clear the TEND flag in ICSR2 in the TEI interrupt handling.
Note that the TEND flag in ICSR2 is automatically set to 0 when data for transmission are written to ICDRT or a stop condition is detected (STOP flag = 1 in ICSR2).

Clear or mask the each flag during interrupt handling.

34.13 Resets and Register and Function States When Issuing Each Condition

The RIIC has reset, RIIC reset, and internal reset functions. Table 34.7 lists the resets and register and function states when issuing each condition.

Table 34.7 Resets and Register and Function States When Issuing Each Condition

		Chip Reset	RIIC Reset (ICE = 0, IICRST = 1)	Internal Reset (ICE = 1, IICRST = 1)	Start Condition/ Restart Condition Detection	Stop Condition Detection
ICCR1	ICE, IICRST	At a reset	Retained	Retained	Retained	Retained

34.14 Event Link Output

The RIIC0 handles event output for the event link controller (ELC) corresponding to the following sources.

(1) Transfer error event

When a transfer error event occurs, the corresponding event signal can be output for another module via the ELC.

(2) Receive data full

When a receive data register becomes full, the corresponding event signal can be output for another module via the ELC.

(3) Transmit data empty

When a transmit data register becomes empty, the corresponding event signal can be output for another module via the ELC.

(4) Transmit end

On completion of transfer, the corresponding event signal can be output for another module via the ELC.

34.14.1 Interrupt Handling and Event Linking

The RIIC module produces four kinds of interrupt: transfer error or event generation (arbitration-lost detection, detection of NACK, detection of timeout, detection of a start condition, or detection of a stop condition), receive data full, transmit data empty, and transmit end interrupts. Each of these has an enable bit to control enabling and disabling of the interrupt signal. An interrupt request signal is output for the CPU when an interrupt source condition is satisfied while the setting of the corresponding enable bit is enabled.

The corresponding event link output signals are sent to other modules as event signals via the ELC when the interrupt source conditions are satisfied, regardless of the settings of the interrupt enable bits.

For details on interrupt sources, see Table 34.6.

34.15 Usage Notes

34.15.1 Setting Module Stop Function

Module-stop state can be entered or canceled using module stop control register B (MSTPCRB). The initial setting is for operation of the RIIC to be stopped. RIIC register access is enabled by clearing the module-stop state.
For details on module stop control registers B, refer to section 9, Low-Power Consumption Function.

35. CAN Interface (RSCAN)

This section contains a generic description of the CAN Interface (RSCAN).

35.1 Overview

35.1.1 Functional Overview

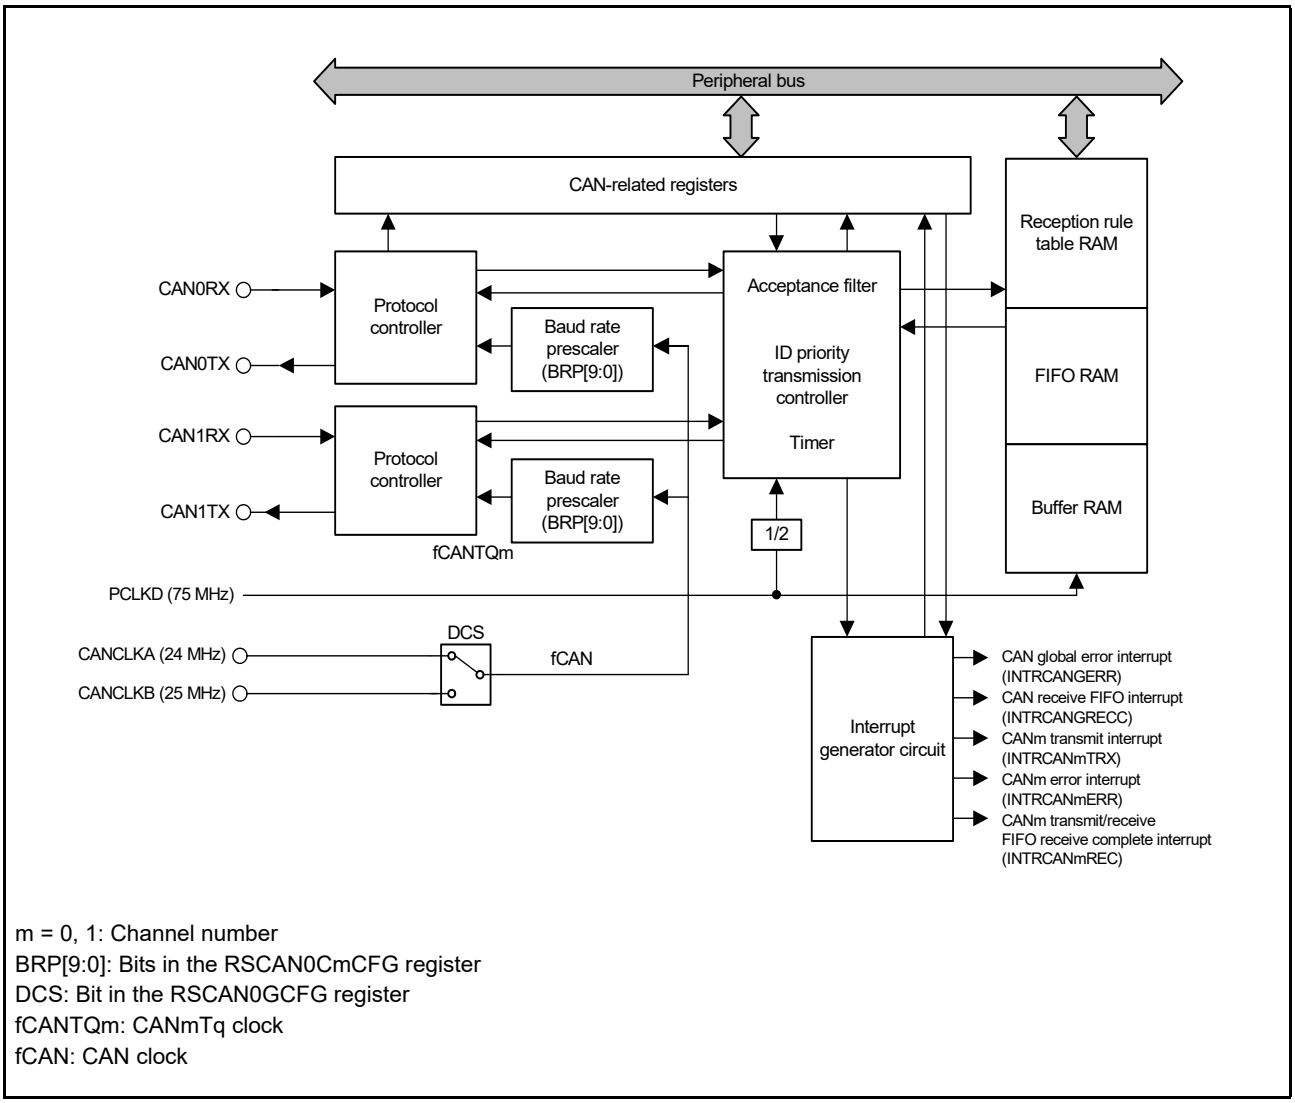
This LSI incorporates one unit of the CAN interface (RSCAN) which consists of two channels (CAN0 and CAN1) of the CAN controller conforming to the ISO11898-1 specifications. Table 35.1 shows the specifications of the RSCAN and Figure 35.1 shows a block diagram of the RSCAN.

Table 35.1 Specifications of the RSCAN (1 / 2)

Item	Specification
Number of channels	2
Protocol	ISO11898-1 compliant (standard or extended frame)
Communication speed	• Maximum 1 Mbps $\text{Communication speed (CANm bit time clock)} = \frac{1}{\text{CANm bit time}}$ CANm bit time = CANmTq × Tq count per bit $\text{CANmTq} = \frac{\text{(BRP[9:0] bits in the RSCAN0CmCFG register + 1)}}{\text{fCAN}}$ m = 0, 1 (channel number) Tq: Time quantum (1 Tq per bit = 1 + TSEG1 + TSEG2) fCAN: Frequency of CAN clock (selected by the DCS bit in the RSCAN0GCFG register)
Buffer	160 buffers in total • Individual buffers: 32 buffers (16 buffers × 2 channels) Transmission buffer: 16 buffers per channel Transmission queue: Single queue per channel (shared with the transmission buffer; up to 16 buffers allocatable) • Shared buffers: 128 buffers for all channels (64 buffers × 2 channels) Reception buffer: 32 buffers (16 buffers × 2 channels) Reception FIFO buffer: 8 FIFO buffers (up to 128 buffers allocatable to each) Transmission/reception FIFO buffer: 3 FIFO buffers per channel (up to 128 buffers allocatable to each) • ECC included
Reception function	• Receives data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be received. • Sets interrupt enable/disable for each FIFO. • Mirror function (reception of messages transmitted from the own CAN node) • Timestamp function (to record message reception time as a 16-bit timer value)
Reception filter function	• Selects received messages according to 128 reception rules. • Sets the number of reception rules (0 to 128) for each channel. • Acceptance filter processing: Sets ID and mask for each reception rule. • DLC filter processing: Enables DLC filter check for each reception rule.
Received message transfer function	• Routing function Transfers received messages to arbitrary destinations (can be transferred to up to 8 buffers) Transfer destination: Reception buffer, reception FIFO buffer, and/or transmission/reception FIFO buffer • Label addition function Stores label information together with a message in a reception buffer and FIFO buffer.
Transmission function	• Transmits data frames and remote frames. • Selects ID format (standard ID, extended ID, or both IDs) to be transmitted. • Sets interrupt enable/disable for each transmission buffer and transmission/reception FIFO buffer. • Selects ID priority transmission or transmission buffer number priority transmission. • Transmission request can be aborted (possible to confirm with a flag) • One-shot transmission function
Interval transmission function	Transmit messages at configurable intervals (transmission mode or gateway mode of transmission/reception FIFO buffers)

Table 35.1 Specifications of the RSCAN (2 / 2)

Item	Specification
Transmission queue function	Transmits all stored messages according to the ID priority.
Transmission history function	Stores the history information of transmission-completed messages
Gateway function	Transmits a received message automatically.
Bus off recovery mode selection	• Selects the method for returning from bus off state. • ISO11898-1 compliant • Automatic entry to channel halt mode at bus-off entry • Automatic entry to channel halt mode at bus-off end • Transition to channel standby mode by program request • Transition to the error-active state by program request (forcible return from the bus off state)
Error status monitoring	• Monitors CAN protocol errors (stuff error, form error, ACK error, CRC error, bit error, ACK delimiter error, and bus dominant lock). • Detects error status transitions (error warning, error passive, bus off entry, and bus off recovery) • Reads the error counter. • Monitors DLC errors.
Interrupt source	8 sources • Global Interrupts (2 sources) CAN receive FIFO interrupt CAN global error interrupt • Channel interrupts (3 sources/channel) (m = 0, 1) CANm transmit interrupt (CANm transmission complete, CANm transmission abort, etc.) CANm transmit/receive FIFO receive complete interrupt CANm error interrupt (bus error, bus lock, etc.)
Error source	An ECC error in the buffer RAM is detected and conveyed to the error control module (ECM). • 1-bit ECC error in the RSCAN RAM. • 2-bit ECC error in the RSCAN RAM. • RSCAN overflow error
Low-power consumption function	The module-stop state can be set.
CAN clock source	PLL0 frequency-division of CANCLKA (24 MHz) or the main clock signal (CANCLKB; 25 MHz) is selectable
Test function	Test function for user evaluation • Listen-only mode • Self-test mode 0 (external loopback) • Self-test mode 1 (internal loopback) • RAM test (read/write test) • Inter-channel communication test



m = 0, 1: Channel number
BRP[9:0]: Bits in the RSCAN0CmCFG register
DCS: Bit in the RSCAN0GCFG register
fCANTQm: CANmTq clock
fCAN: CAN clock

Figure 35.1 Block Diagram of the RSCAN

Table 35.2 lists the I/O pins used in the RSCAN.

Table 35.2 RSCAN Pin Configuration

Channel	Pin Name	I/O	Function
CAN0	CRXD0	Input	CAN0 receive data input pin
	CTXD0	Output	CAN0 transmit data output pin
CAN1	CRXD1	Input	CAN1 receive data input pin
	CTXD1	Output	CAN1 transmit data output pin

Table 35.3 lists the meanings of indices used throughout this section.

Table 35.3 Index

Index	Meaning
m	Throughout this section, the individual channels of RSCAN units are generically indicated by the index “m” (m = 0, 1); for example, RSCAN0CmSTS is the channel m status register.
j	The individual registers associated with reception rule table are generically indicated by the index “j” (j = 0 to 15); for example, RSCAN0GAFLIDj is the reception rule ID register.
k	The individual transmission/reception FIFO buffers are generically indicated by the index “k” (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1); for example, RSCAN0CFCCk is the transmission/reception FIFO buffer configuration/control register.
x	The individual reception FIFO buffers in the RSCAN units are identified by the index “x” (x = 0 to 7): for example, RSCAN0RFSTSx is the reception FIFO buffer status register in the RSCAN0 unit.
q	The individual reception buffers are generically indicated by the index “q” (q = 0 to 15 for channel 0; q = 16 to 31 for channel 1); for example, RSCAN0RMIDq is the reception buffer ID register.
p	The individual transmission buffers are generically indicated by the index “p” (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1); for example, RSCAN0TMCp is the transmission buffer control register.
r	The individual RAM tests for CAN are generically indicated by the index “r” (r = 0 to 63); for example, RSCAN0RPGACCr is the RAM test page access register.
z	The individual ECC error address registers for CAN are generically indicated by the index “z” (z = 0 to 7).

35.2 Register Descriptions

35.2.1 Channel Configuration Registers (RSCAN0CmCFG) (m = 0, 1)

The RSCAN0CmCFG registers control the settings for clock timing on each channel.
Modify the RSCAN0CmCFG registers in channel reset mode or channel halt mode. Set these registers in channel reset mode before shifting to channel communication mode or channel wait mode. For a description of the bit timing parameters and settings, see section 35.9.1, Initial Settings.

BRP[9:0] Bits (Prescaler Division Ratio Set)

The CANmTq clock (fCANTQm) is calculated by dividing the CAN clock (fCAN) by the baud rate prescaler, ((BRP[9:0]) + 1). One clock cycle of the CANmTq clock is 1 Time Quantum (Tq) (m = 0, 1).

TSEG1[3:0] Bits (Time Segment 1 Control)

These bits are used to specify a Tq value for the total length of the propagation segment (PROP_SEG) and phase segment 1 (PHASE_SEG1).
Allowed values are 4 Tq to 16 Tq, inclusive.

TSEG2[2:0] Bits (Time Segment 2 Control)

These bits are used to specify a Tq value for the length of phase segment 2 (PHASE_SEG2).
Allowed values are 2 Tq to 8 Tq, inclusive.
Set a value smaller than the value of the TSEG1 bits.

SJW[1:0] Bits (Resynchronization Jump Width Control)

These bits are used to specify a Tq value for the resynchronization jump width. Allowed values are 1 Tq to 4 Tq, inclusive.
Set a value less than or equal to the value of the TSEG2 bits. For the Tq value, see the description of BRP[9:0] bits.

35.2.2 Channel Control Registers (RSCAN0CmCTR) (m = 0, 1)

The RSCAN0CmCTR registers control the operating mode of and the settings for interrupts from each channel.

Address(es): RSCAN.RSCAN0C0CTR A007 8004h, RSCAN.RSCAN0C1CTR A007 8014h

b31 to b27	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CHMDC[1:0] Bits (Mode Select)

These bits are used to select a channel mode (channel communication mode, channel reset mode, or channel halt mode). For details, see section 35.4.2, Channel Modes. Setting the CSLPR bit to 1 in channel reset mode allows transition to channel stop mode. Do not set the CHMDC[1:0] bits to 11b. When the CAN module has automatically transitioned to channel halt mode based on the setting of the BOM[1:0] bits, the CHMDC[1:0] bits automatically become 10b.

CSLPR Bit (Channel Stop Mode)

Setting this bit to 1 places the channel into channel stop mode.
Clearing this bit to 0 makes the channel exit channel stop mode.
This bit should not be modified in channel communication mode or channel wait mode.

RTBO Bit (Forcible Return from Bus-off)

Setting this bit to 1 in the bus off state forcibly returns the state from the bus off state to the error active state. This bit is automatically cleared to 0. Setting this bit to 1 clears the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register to 00h and also clears the BOSTS flag in the RSCAN0CmSTS register to 0 (not in bus off state). The other registers remain unchanged. No bus off recovery interrupt request is generated upon return from the bus off state in this case. Use this bit only when the BOM[1:0] bits in the RSCAN0CmCTR register are 00b (ISO11898-1 compliant).
A delay of up to one CANm bit time occurs after the RTBO bit is set to 1 until the RSCAN module transitions to the error active state. Set this bit to 1 in channel communication mode.

BEIE Bit (Bus Error Interrupt Enable)

When the BEF flag in the RSCAN0CmERFL register is set to 1 with the BEIE bit set to 1, a CANm error interrupt request (bus error interrupt) is generated. Modify this bit in channel reset mode.

EWIE Bit (Error Warning Interrupt Enable)

When the EWF flag in the RSCAN0CmERFL register is set to 1 with the EWIE bit set to 1, a CANm error interrupt request (error warning interrupt) is generated. Modify this bit in channel reset mode.

EPIE Bit (Error Passive Interrupt Enable)

When the EPF flag in the RSCAN0CmERFL register is set to 1 with the EPIE bit set to 1, a CANm error interrupt request (error passive interrupt) is generated. Modify this bit in channel reset mode.

BOEIE Bit (Bus Off Entry Interrupt Enable)

When the BOEF flag in the RSCAN0CmERFL register is set to 1 with the BOEIE bit set to 1, a CANm error interrupt request (bus off entry interrupt) is generated. Modify this bit in channel reset mode.

BORIE Bit (Bus Off Recovery Interrupt Enable)

When the BORF flag in the RSCAN0CmERFL register is set to 1 with the BORIE bit set to 1, a CANm error interrupt request (bus off recovery interrupt) is generated. Modify this bit in channel reset mode.

OLIE Bit (Overload Frame Transmit Interrupt Enable)

When the OVLF flag in the RSCAN0CmERFL register is set to 1 with the OLIE bit set to 1, a CANm error interrupt request (overload frame interrupt) is generated. Modify this bit in channel reset mode.

BLIE Bit (Bus Lock Interrupt Enable)

When the BLF flag in the RSCAN0CmERFL register is set to 1 with the BLIE bit set to 1, a CANm error interrupt request (bus lock interrupt) is generated. Modify this bit in channel reset mode.

ALIE Bit (Arbitration Lost Interrupt Enable)

When the ALF flag in the RSCAN0CmERFL register is set to 1 with the ALIE bit set to 1, a CANm error interrupt request (arbitration lost interrupt) is generated. Modify this bit in channel reset mode.

TAIE Bit (Transmission Abort Interrupt Enable)

When transmission abort of the transmission buffer is completed with the TAIE bit set to 1, a CANm transmission interrupt request (transmission abort interrupt) is generated. Modify this bit only in channel reset mode.

BOM[1:0] Bits (Bus Off Recovery Mode Select)

These bits are used to select the bus off recovery mode of the RSCAN module.

When the BOM[1:0] bits are set to 00b, return from the bus off state to the error active state is compliant with the CAN specifications. That is, the RSCAN module reenters the CAN communication (error active state) after 11 consecutive recessive bits are detected 128 times. A bus off recovery interrupt request is generated at the time of return from the bus off state. Even if the CHMDC[1:0] bits are set to 10b (channel halt mode) before recessive bits are detected 128 times, the RSCAN module does not transition to channel halt mode until recessive bits are detected 128 times.

When the RSCAN module reaches the bus off state when the BOM[1:0] bits are set to 01b, the CHMDC[1:0] bits in the RSCAN0CmCTR register (m = 0, 1) are set to 10b and the RSCAN module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register are cleared to 00h.

When the RSCAN module reaches the bus off state when the BOM[1:0] bits are set to 10b, the CHMDC[1:0] bits are set to 10b and the RSCAN module transitions to channel halt mode after return from the bus off state (11 consecutive recessive bits are detected 128 times). A bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00h.

When the BOM[1:0] bits are set to 11b and the CHMDC[1:0] bits are set to 10b while the RSCAN module is in the bus off state, the RSCAN module transitions to channel halt mode. No bus off recovery interrupt request is generated at the time of return from the bus off state and the TEC[7:0] and REC[7:0] bits are cleared to 00h. However, if 11 consecutive recessive bits are detected 128 times and the RSCAN module has recovered to the error active state from the bus off state before the CHMDC[1:0] bits are set to 10b, a bus off recovery interrupt request is generated.

If a program writes to the CHMDC[1:0] bit at the same time as the RSCAN module transition to channel halt mode (at bus off entry when the BOM[1:0] bits are 01b or at bus off end when the BOM[1:0] bits are 10b), the program's writing takes precedence. Modify the BOM[1:0] bits in channel reset mode.

ERRD Bit (Error Display Mode Select)

This bit is used to control the display mode of bits 14 to 8 in the RSCAN0CmERFL register.
When this bit is clear to 0, only the flags of the first error event are set to 1. If two or more errors occur in the first error event, all the flags of the detected errors are set to 1.
When this bit is set to 1, all the flags of errors that have occurred are set to 1 regardless of the error occurrence order.
Modify this bit in channel reset mode or channel halt mode.

CTMS[1:0] Bits (Communication Test Mode Select)

These bits are used to select a communication test mode. Modify these bits in channel halt mode. These bits are set to 0 in channel reset mode.

35.2.3 Channel Status Register (RSCAN0CmSTS) (m = 0, 1)

The RSCAN0CmSTS registers are status registers that indicate the state of transfer on each channel.

Address(es): RSCAN.RSCAN0C0STS A007 8008h, RSCAN.RSCAN0C1STS A007 8018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b5	TRMSTS	Transmission Status Flag	0: Bus idle or in reception 1: In transmission or bus off state	R
b6	RECSTS	Reception Status Flag	0: Bus idle, in transmission or bus off state 1: In reception	R
b7	COMSTS	Communication Status Flag	0: Communication is not ready. 1: Communication is ready.	R
b15 to b8	—	Reserved	These bits are read as 0.	R
b23 to b16	REC[7:0]	Receive Error Counter	The receive error counter (REC) can be read.	R
b31 to b24	TEC[7:0]	Transmit Error Counter	The transmit error counter (TEC) can be read.	R

CRSTSTS Flag (Channel Reset Status Flag)

This flag is set to 1 when the CAN module has transitioned to channel reset mode, and is cleared to 0 when the CAN module has transitioned to channel communication mode or channel halt mode. This flag remains 1 when the CAN module transitions from channel reset mode to channel stop mode.

CHLTSTS Flag (Channel Halt Status Flag)

This flag is set to 1 when the CAN module has transitioned to channel halt mode, and is cleared to 0 when the CAN module has returned from channel halt mode.

CSLPSTS Flag (Channel Stop Status Flag)

This flag is set to 1 when the CAN module has transitioned to channel stop mode, and is cleared to 0 when the CAN module has returned from channel stop mode.

EPSTS Flag (Error Passive Status Flag)

This flag is set to 1 when the RSCAN module has entered the error passive state ((128 ≤ TEC[7:0] ≤ 255) or (128 ≤ REC[7:0])). It is cleared to 0 when the RSCAN module has exited the error passive state or has entered channel reset mode.

BOSTS Flag (Bus Off Status Flag)

This flag is set to 1 when the bus off state (TEC[7:0] > 255) is entered. It is cleared to 0 when the CAN module has exited the bus off state.

TRMSTS Flag (Transmission Status Flag)

This flag is set to 1 when transmission has started, and is cleared to 0 when the bus has become idle or reception has started. This flag remains 1 in the bus off state.

RECSTS Flag (Reception Status Flag)

This flag is set to 1 when reception has started, and is cleared to 0 when the bus has become idle or transmission has started.

COMSTS Flag (Communication Status Flag)

This bit indicates that communication is ready.
This flag becomes 1 when the CAN module has detected 11 consecutive recessive bits after it has transitioned from channel reset mode or channel halt mode to channel communication mode. This flag is cleared to 0 in channel reset mode or channel halt mode.

REC[7:0] Bits (Receive Error Counter)

These bits contain the receive error counter value. For receive error counter increment/decrement conditions, see the CAN specifications (ISO11898-1).
These bits are cleared to 0 in channel reset mode.

TEC[7:0] Bits (Transmit Error Counter)

These bits contain the transmit error counter value. For transmit error counter increment/decrement conditions, see the CAN specification (ISO11898-1).
These bits are cleared to 0 in channel reset mode.

35.2.4 Channel Error Flag Registers (RSCAN0CmERFL) (m = 0, 1)

The RSCAN0CmERFL registers are status registers that indicate the state of error detection on each channel.
See the CAN specification (ISO11898-1) for a description of error occurrence conditions. To clear each flag of these registers, the program must write a 0 to the corresponding bit. Writing 1 to these flags does not change them to 1. If any of these flags is set to 0 at the same time that the program writes 0 to the flag, the flag is still set to 1. The channel reset mode transition clears all of these flags to 0.
If the ERRD bit in the RSCAN0CmCTR registers is set to 0 (i.e., only the flags for the first error event are displayed) and an error related to bits 14 to 8 of RSCAN0CmERFL is detected, the flag bits are only set by the error event if bits 14 to 8 were all 0 at the when time the error occurred.

Address(es): RSCAN.RSCAN0C0ERFL A007 800Ch, RSCAN.RSCAN0C1ERFL A007 801Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b13	B0ERR	Dominant Bit Error Flag	0: No dominant bit error is detected. 1: Dominant bit error is detected.	R/W *1
b14	ADERR	ACK Delimiter Error Flag	0: No ACK delimiter error is detected. 1: ACK delimiter error is detected.	R/W *1
b15	—	Reserved	This bit is read as 0.	R

Bit	Symbol	Bit Name	Description	R/W
b30 to b16	CRCREG [14:0]	CRC Calculation Data	A CRC value calculated based on the transmitted or received message is indicated.	R
b31	—	Reserved	This bit is read as 0.	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

BEF Flag (Bus Error Flag)

This flag is set to 1 when any one of the ADERR, B0ERR, B1ERR, CERR, AERR, FERR, and SERR flags in the RSCAN0CmERFL register is set to 1.

EWF Flag (Error Warning Flag)

This flag is set to 1 only when the REC[7:0] or TEC[7:0] value first exceeds 95. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 95, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 95 or less and then the REC[7:0] or TEC[7:0] value exceeds 95 again.

EPF Flag (Error Passive Flag)

This flag becomes 1 when the error passive state is reached (REC[7:0] or TEC[7:0] value > 127).
This flag becomes 1 only when the REC[7:0] or TEC[7:0] value first exceeds 127. Therefore, if the program writes 0 to this flag while the value of REC[7:0] or TEC[7:0] remains over 127, this bit is not set to 1 until both REC [7:0] and TEC[7:0] values become 127 or less and then the REC[7:0] or TEC[7:0] value exceeds 127 again.

BOEF Flag (Bus Off Entry Flag)

This flag is set to 1 when the bus off state is reached (TEC[7:0] value > 255). This flag is also set to 1 if the bus off state is reached when the BOM[1:0] bits in the RSCAN0CmCTR register (m = 0, 1) set to 01b (transition to channel halt mode at bus off entry).

BORF Flag (Bus Off Recovery Flag)

This flag is set to 1 when 11 consecutive recessive bits have been detected 128 times and the CAN module returns from the bus off state. However, this flag is not set to 1 if the CAN module returns from the bus off state in any of the following ways before 11 consecutive recessive bits are detected 128 times.

- The CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 01b (channel reset mode).
- The RTBO bit in the RSCAN0CmCTR register is set to 1 (forcible return from the bus off state is made).
- The BOM[1:0] bits in the RSCAN0CmCTR register are set to 01b (transition to channel halt mode at bus off entry).
- The CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 10b (channel halt mode) before 11 consecutive recessive bits are detected 128 times with the BOM[1:0] bits set to 11b (transition to channel halt mode upon a request from the program during bus off).

OVLF Flag (Overload Flag)

This flag is set to 1 when the overload frame transmit condition has been detected when performing reception or transmission.

BLF Flag (Bus Lock Flag)

This flag is set to 1 when 32 consecutive dominant bits have been detected on the CAN bus in channel communication mode. After that, detection of a dominant lock is restarted when either of the following conditions is met.

- A recessive bit is detected after the BLF bit has been cleared from 1 to 0.
- The CAN module transitions to channel reset mode and returns to channel communication mode after the BLF bit has been cleared from 1 to 0.

ALF Flag (Arbitration-lost Flag)

This flag is set to 1 when an arbitration-lost has been detected.

SERR Flag (Stuff Error Flag)

This flag is set to 1 when a stuff error has been detected.

FERR Flag (Form Error Flag)

This flag is set to 1 when a form error has been detected.

AERR Flag (ACK Error Flag)

This flag is set to 1 when an ACK error has been detected.

CERR Flag (CRC Error Flag)

This flag is set to 1 when a CRC error has been detected.

B1ERR Flag (Recessive Bit Error Flag)

This flag is set to 1 when a dominant bit has been detected though a recessive bit was transmitted.

B0ERR Flag (Dominant Bit Error Flag)

This flag is set to 1 when a recessive bit has been detected though a dominant bit was transmitted.

ADERR Flag (ACK Delimiter Error Flag)

This flag is set to 1 when a form error has been detected in the ACK delimiter during transmission.

CRCREG[14:0] Flag (CRC Calculation Data)

When the CTME bit in the RSCAN0CmCTR register is set to 1 (communication test mode is enabled), the CRC value calculated based on the transmitted or received message can be read. When the CTME bit is set to 0 (communication test mode is disabled), these bits are always read as 0.

35.2.5 Global Configuration Register (RSCAN0GCFG)

The RSCAN0GCFG register controls the settings for the clock signals in the RSCAN module as a whole, interval timers, etc.

Modify the RSCAN0GCFG register in global reset mode.

Address(es): RSCAN.RSCAN0GCFG A007 8084h

Bit	Symbol	Bit Name	Description	R/W
b31 to b16	ITRCP[15:0]	Interval Timer Prescaler Set	When these bits are set to M, the PCLKD (75 MHz) is divided by M. Setting 0000h is prohibited when the interval timer is in use.	R/W

Note 1. When specifying PCLKD/2 as the timestamp counter count source, set bits TSBTCS[2:0] to 000b.

TPRI Bit (Transmit Priority Select)

This bit is used to set the transmit priority.
When this bit is set to 0, ID priority is selected and the transmit priority complies with the CAN bus arbitration rule (ISO11898-1 specifications). When this bit is set to 1, transmission buffer number priority is selected and the lowest transmission buffer number of those has the highest priority.
While the transmission queue is in use, this bit should be set to 0.

DCE Bit (DLC Check Enable)

Setting this bit to 1 makes the DLC check function available. When disabling the DLC check function, set the GAFLDLC[3:0] bits in the RSCAN0GAFLP0j register to 0000b before clearing the DCE bit in the RSCAN0GCFG register to 0.

DRE Bit (DLC Replacement Enable)

When the DRE bit is set to 1, the DLC value of the reception rule is stored in the buffer instead of the DLC value of the received message after the DLC value has passed through the DLC filter. In this case, a value of 00h is stored in each data byte beyond the DLC value of the reception rule.
The DLC replacement function is only available when the DCE bit is set to 1 (DLC check is enabled).

MME Bit (Mirror Function Enable)

Setting this bit to 1 makes the mirror function available.

DCS Bit (CAN Clock Source Select)

When this bit is set to 0, CANCLKA (24 MHz) is used as the clock source of the CAN clock (fCAN).
When this bit is set to 1, CANCLKB (25 MHz) is used as the clock source of the CAN clock (fCAN).

TSP[3:0] Bits (Timestamp Clock Source Division)

A clock obtained by dividing the clock source selected with the TSBTCS[2:0] bits and TSSS bit according to the TSP[3:0] bits is used as the timestamp counter count source.

TSSS Bit (Timestamp Source Select)

This bit is used to select a clock source of the timestamp counter.

TSBTCS[2:0] Bits (Timestamp Clock Source Select)

When the TSSS bit is 1, these bits are used to select the channel of the bit time clock that will be the clock source of the timestamp counter.

ITRCP[15:0] Bits (Interval Timer Prescaler Set)

These bits are used to set a clock source division value of the interval timer for FIFO buffers. See section 35.6.3.1, Interval Transmission Function.

35.2.6 Global Control Register (RSCAN0GCTR)

The RSCAN0GCTR register controls the operating mode of the RSCAN module and global interrupts.

Address(es): RSCAN.RSCAN0GCTR A007 8088h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	TSRST
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	THLEIE	MEIE	DEIE	—	—	—	—	—	GSLPR	GMDC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	GMDC[1:0]	Global Mode Select	b1 b0 0 0: Global operating mode 0 1: Global reset mode 1 0: Global test mode Setting other than above is prohibited.	R/W
b2	GSLPR	Global Stop Mode	0: Other than global stop mode 1: Global stop mode	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	DEIE	DLC Error Interrupt Enable	0: DLC error interrupt is disabled. 1: DLC error interrupt is enabled.	R/W
b9	MEIE	FIFO Message Lost Interrupt Enable	0: FIFO message lost interrupt is disabled. 1: FIFO message lost interrupt is enabled.	R/W
b10	THLEIE	Transmission History Buffer Overflow Interrupt Enable	0: Transmission history buffer overflow interrupt is disabled. 1: Transmission history buffer overflow interrupt is enabled.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b16	TSRST	Timestamp Counter Reset	Setting the TSRST bit to 1 resets the timestamp counter. This bit is always read as 0.	R/W
b31 to b17	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

GMDC[1:0] Bits (Global Mode Select)

These bits are used to select the mode of entire RSCAN module (global operating mode, global reset mode, or global test mode). For details, see section 35.4.1, Global Modes. Setting the GSLPR bit to 1 when in global reset mode places the RSCAN module into global stop mode.

GSLPR Bit (Global Stop Mode)

Setting this bit to 1 places the RSCAN module into global stop mode.
Clearing this bit to 0 makes the RSCAN module leave from global stop mode.
This bit should not be modified in global operating mode or global test mode.

DEIE Bit (DLC Error Interrupt Enable)

When the DEIE bit is set to 1 and the DEF flag in the RSCAN0GERFL register is set to 1, a CAN global error interrupt request (DLC error interrupt) is generated. Modify this bit in global reset mode.

MEIE Bit (FIFO Message Lost Interrupt Enable)

When the MEIE bit is set to 1 and the MES flag in the RSCAN0GERFL register is set to 1, a CAN global error interrupt request (FIFO message lost interrupt) is generated. Modify this bit in global reset mode.

THLEIE Bit (Transmission History Buffer Overflow Interrupt Enable)

When the THLEIE bit is set to 1 and the THLES flag in the RSCAN0GERFL register is set to 1, a CAN global error interrupt request (transmission history buffer overflow interrupt) is generated. Modify this bit in global reset mode.

TSRST Bit (Timestamp Counter Reset)

This bit is used to reset the timestamp counter. When this bit is set to 1, the RSCAN0GTSC register is cleared to 0000h.

35.2.7 Global Status Register (RSCAN0GSTS)

The RSCAN0GSTS register is a status register that indicates the operating state of the RSCAN module as a whole.

Address(es): RSCAN.RSCAN0GSTS A007 808Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	GRAMINIT	GSLPSTS	GHLTSTS	GRSTSTS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	GRSTSTS	Global Reset Status Flag	0: Not in global reset mode 1: In global reset mode	R
b1	GHLTSTS	Global Test Status Flag	0: Not in global test mode 1: In global test mode	R
b2	GSLPSTS	Global Stop Status Flag	0: Not in global stop mode 1: In global stop mode	R
b3	GRAMINIT	CAN RAM Initialization Status Flag	0: CAN RAM initialization is completed. 1: CAN RAM initialization is ongoing.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

GRSTSTS Flag (Global Reset Status Flag)

This flag is set to 1 when the CAN module has transitioned to global reset mode, and is cleared to 0 when the CAN module has exited global reset mode. This flag remains 1 even when the CAN module has transitioned from global reset mode to global stop mode.

GHLTSTS Flag (Global Test Status Flag)

This flag is set to 1 when the CAN module has transitioned to global test mode, and is cleared to 0 when the CAN module has exited global test mode.

GSLPSTS Flag (Global Stop Status Flag)

This flag is set to 1 when the CAN module has transitioned to global stop mode, and is cleared to 0 when the CAN module has returned from global stop mode.

GRAMINIT Flag (CAN RAM Initialization Status Flag)

This flag indicates the initialization status of the CAN RAM.

This flag is set to 1 after the MCU has been reset, and is cleared to 0 when CAN RAM initialization is completed.

35.2.8 Global Error Flag Register (RSCAN0GERFL)

The RSCAN0GERFL register is a status register that indicates the error state of the RSCAN module as a whole.
All flags in the RSCAN0GERFL register are cleared to 0 in global reset mode.

Address(es): RSCAN.RSCAN0GERFL A007 8090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	THLES	MES	DEF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DEF	DLC Error Flag	0: No DLC error has occurred. 1: A DLC error has occurred.	R/W *1
b1	MES	FIFO Message Lost Status Flag	0: No FIFO message lost error has occurred. 1: A FIFO message lost error has occurred.	R
b2	THLES	Transmission History Buffer Overflow Status Flag	0: No transmission history buffer overflow has occurred. 1: A transmission history buffer overflow has occurred.	R
b31 to b3	—	Reserved	These bits are read as 0.	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

DEF Flag (DLC Error Flag)

The DEF flag is set to 1 when an error has been detected during the DLC check. This flag can be cleared by writing 0 to it.

MES Flag (FIFO Message Lost Status Flag)

The MES flag is set to 1 when any one of the RFMLT flags in the RSCAN0RFSTSx register (x = 0 to 7) or the CFMLT flags in the RSCAN0CFSTSk register (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1) is set to 1.
This flag is cleared to 0 when all RFMLT flags and CFMLT flags are set to 0.

THLES Flag (Transmission History Buffer Overflow Status Flag)

The THLES flag is set to 1 when any one of the THLELT flags in the RSCAN0THLSTSm register (m = 0, 1) is set to 1.
This flag is cleared to 0 when the THLELT flags of all channels are set to 0.

35.2.9 Global TX Interrupt Status Register 0 (RSCAN0GTINTSTS0)

The RSCAN0GTINTSTS0 register is a status register that indicates the state of interrupts in CANm transmission by the RSCAN module (m = 0, 1).

Address(es): RSCAN.RSCAN0GTINTSTS0 A007 8460h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	THIF1	CFTIF1	TQIF1	TAIF1	TSIF1	—	—	—	THIF0	CFTIF0	TQIF0	TAIF0	TSIF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSIF0	Channel 0 Transmission Buffer Interrupt Status Flag	0: Transmission buffer transmission complete interrupt is not requested. 1: Transmission buffer transmission complete interrupt is requested.	R*1
b1	TAIF0	Channel 0 Transmission Buffer Transmission Abort Interrupt Status Flag	0: Transmission buffer transmission abort interrupt is not requested. 1: Transmission buffer transmission abort interrupt is requested.	R*1
b2	TQIF0	Channel 0 Transmission Queue Interrupt Status Flag	0: Transmission queue interrupt is not requested. 1: Transmission queue interrupt is requested.	R*1
b3	CFTIF0	Channel 0 Transmit/Receive FIFO Transmit Interrupt Status Flag	0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.	R*1
b4	THIF0	Channel 0 Transmission History Interrupt Status Flag	0: Transmission history interrupt is not requested. 1: Transmission history interrupt is requested.	R*1
b7 to b5	—	Reserved	These bits are read as 0.	R
b8	TSIF1	Channel 1 Transmission Buffer Interrupt Status Flag	0: Transmission buffer transmission complete interrupt is not requested. 1: Transmission buffer transmission complete interrupt is requested.	R*1
b9	TAIF1	Channel 1 Transmission Buffer Transmission Abort Interrupt Status Flag	0: Transmission buffer transmission abort interrupt is not requested. 1: Transmission buffer transmission abort interrupt is requested.	R*1
b10	TQIF1	Channel 1 Transmission Queue Interrupt Status Flag	0: Transmission queue interrupt is not requested. 1: Transmission queue interrupt is requested.	R*1
b11	CFTIF1	Channel 1 Transmit/Receive FIFO Transmit Interrupt Status Flag	0: Transmit/receive FIFO transmit interrupt is not requested. 1: Transmit/receive FIFO transmit interrupt is requested.	R*1
b12	THIF1	Channel 1 Transmission History Interrupt Status Flag	0: Transmission history interrupt is not requested. 1: Transmission history interrupt is requested.	R*1
b31 to b13	—	Reserved	These bits are read as 0.	R

Note 1. This bit is automatically cleared in the global reset or channel reset mode.

TSIFm Bits (Channel m Transmission Buffer Interrupt Status Flag) (m = 0, 1)

The TSIFm bit is set to 1 when the TMIE bit in the RSCAN0TMIEC0 register is set to 1 (transmission buffer interrupt enabled) and the TMTRF[1:0] flag in the RCAN0TMSTSp (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1) register are set to 10b (transmission completed without abort request) or 11b (transmission completed with abort request).
When the TMTRF[1:0] flag are cleared to 00b under the condition that the TSIFm bit can be set to 1, this flag is cleared to 0. In addition, clearing the TMIE bit to 0 also clears this flag to 0.

TAIFm Bits (Channel m Transmission Buffer Transmission Abort Interrupt Status Flag) (m = 0, 1)

The TAIFm bit is set to 1 when the TAIE bit in the RSCAN0CmCTR register is 1 (transmission abort interrupt enabled) and the TMTRF[1:0] flag in the RCAN0TMSTSp (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1) register are set to 01b (transmission abort completed).
This flag is cleared to 0 when the TMTRF[1:0] flag are cleared to 00b after the transmission abort is completed.

TQIFm Bits (Channel m Transmission Queue Interrupt Status Flag) (m = 0, 1)

When the TXQIE bit in the RSCAN0TXQCCm register is set to 1 (transmission queue interrupt enabled) and the TXQIF bit in the RSCAN0TXQSTSm register is set to 1 (transmission queue interrupt request), the TQIFm bit is set to 1.
When the TXQIF bit (transmission queue interrupt request) in the RSCAN0TXQSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the TXQIE bit is cleared to 0.

CFTIFm Bits (Channel m Transmit/Receive FIFO Transmit Interrupt Status Flag) (m = 0, 1)

When the CFTXIE bit in the RSCAN0CFCCk register is set to 1 (transmit/receive FIFO transmit interrupt enabled) and the CFTXIF bit in the RSCAN0CFSTSk (k = 0 to 2 for channel 0; p = 3 to 5 for channel 1) register is set to 1 (transmit/receive FIFO transmit interrupt request), the CFTIFm bit is set to 1.
When the CFTXIF bit is cleared to 0 under the conditions that the CFTIFm bit can be set to 1, this bit is cleared to 0. This flag is also cleared to 0 when the CFTXIE bit is cleared to 0.

THIFm Bits (Channel m Transmission History Interrupt Status Flag) (m = 0, 1)

When the THLIE bit in the RSCAN0THLCCm register is set to 1 (transmission history interrupt enabled) and the THLIF bit in the RSCAN0THLSTSm register is set to 1 (transmission history interrupt request), the THIFm bit is set to 1.
When the THLIF bit in the RSCAN0THLSTSm register is cleared to 0, this bit is cleared to 0. This flag is also cleared to 0 when the THLIE bit is cleared to 0.

35.2.10 Global Timestamp Counter Register (RSCAN0GTSC)

The RSCAN0GTSC register is a 32-bit counter that indicates the timestamp counter value.

Address(es): RSCAN.RSCAN0GTSC A007 8094h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TS[15:0]	Timestamp Value	The timestamp counter value can be read. Counter Value: 0000h to FFFFh	R
b31 to b16	—	Reserved	These bits are read as 0.	R

TS[15:0] Bits (Timestamp Value)

When the TS[15:0] bits are read, the read value shows the timestamp counter (16-bit free-running counter) value at that time. When the SOF is detected, the TS[15:0] value is captured and later stored in the reception buffer or the FIFO buffer. The timestamp counter is initialized in global reset mode.

The timestamp counter starts and stops counting differently, depending on the count source.

- When the TSSS bit in the RSCAN0GCFG register is 0 (PCLKD/2):
  The timestamp counter starts counting when the RSCAN module has transitioned to global operating mode.
  This counter stops counting when the RSCAN module has transitioned to global stop mode or global test mode.
- When the TSSS bit is 1 (CANm bit time clock):
  The timestamp counter starts counting when the corresponding channel has transitioned to channel communication mode.
  This counter stops counting when the corresponding channel has transitioned to channel reset mode or channel halt mode.

35.2.11 Reception Rule Entry Control Register (RSCAN0GAFLECTR)

The RSCAN0GAFLECTR register controls the reception rule table.

Address(es): RSCAN.RSCAN0GAFLECTR A007 8098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	AFLDAE	—	—	—	AFLPN[4:0]				
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	AFLPN[4:0]	Reception Rule Table Page Number Configuration	A page number can be selected from a range of page 0 (00000b) to page 7 (00111b).	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	AFLDAE	Reception Rule Table Write Enable	0: Writing to the reception rule table is disabled. 1: Writing to the reception rule table is enabled.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

AFLPN[4:0] Bits (Reception Rule Table Write Enable)

These bits are used to set the page number of the reception rule table. Sixteen reception rules can be set per page.
Set these bits to a value within the range of 00000b to 00111b.

AFLDAE Bit (Reception Rule Table Page Number Configuration)

Setting this bit to 0 disables writing to the reception rule table. After writes to the reception rule table are completed, set this bit to 0 to disable writing to the table. The reception rule table can be read regardless of the value of this bit.
Set the AFLDAE bit to 1 only in global reset mode.

35.2.12 Reception Rule Configuration Register 0 (RSCAN0GAFLCFG0)

The RSCAN0GAFLCFG0 register controls the settings for the number of reception rules for each channel.
Modify the RSCAN0GAFLCFG0 register in global reset mode.
Up to 64 × (number of channels) rules can be registered in the reception rule table as the entire unit. The number of reception rules per channel should meet the following conditions.

- The maximum number of rules per channel is 128.
- The total of the number of rules allocated to each channel does not exceed 128 rules that can be registered in the entire unit.

Address(es): RSCAN.RSCAN0GAFLCFG0 A007 809Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RNC0[7:0]								RNC1[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	RNC1[7:0]	Channel 1 Rule Number Set	Set the number of reception rules exclusively used for channel 1.	R/W
b31 to b24	RNC0[7:0]	Channel 0 Rule Number Set	Set the number of reception rules exclusively used for channel 0.	R/W

RNC1[7:0] Bits (Channel 1 Rule Number Set)

These bits are used to set the number of rules to be registered in the channel 1 reception rule table.
Set these bits to a value within the range of 00h to 80h.

RNC0[7:0] Bits (Channel 0 Rule Number Set)

These bits are used to set the number of rules to be registered in the channel 0 reception rule table.
Set these bits to a value within the range of 00h to 80h.

35.2.13 Reception Rule ID Register (RSCAN0GAFLIDj) (j = 0 to 15)

The RSCAN0GAFLIDj registers control the ID and frame formats of the reception rule.
Modify the RSCAN0GAFLIDj registers when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (enabling writing to the reception rule table) in global reset mode.

Address(es): RSCAN.RSCAN0GAFLID0 A007 8500h, RSCAN.RSCAN0GAFLID1 A007 8510h, RSCAN.RSCAN0GAFLID2 A007 8520h, RSCAN.RSCAN0GAFLID3 A007 8530h, RSCAN.RSCAN0GAFLID4 A007 8540h, RSCAN.RSCAN0GAFLID5 A007 8550h, RSCAN.RSCAN0GAFLID6 A007 8560h, RSCAN.RSCAN0GAFLID7 A007 8570h, RSCAN.RSCAN0GAFLID8 A007 8580h, RSCAN.RSCAN0GAFLID9 A007 8590h, RSCAN.RSCAN0GAFLID10 A007 85A0h, RSCAN.RSCAN0GAFLID11 A007 85B0h, RSCAN.RSCAN0GAFLID12 A007 85C0h, RSCAN.RSCAN0GAFLID13 A007 85D0h, RSCAN.RSCAN0GAFLID14 A007 85E0h, RSCAN.RSCAN0GAFLID15 A007 85F0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	GAFLIDE	GAFLRTR	GAFLLB	GAFLID[28:0]												
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GAFLID[28:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	GAFLID[28:0]	ID Configuration	Set the ID of the reception rule. For the standard ID, set the ID in bits b10 to b0 and set bits b28 to b11 to 0.	R/W
b29	GAFLLB	Reception Rule Target Message Select	0: When a message transmitted from another CAN node is received 1: When the own transmitted message is received	R/W
b30	GAFLRTR	RTR Select	0: Data frame 1: Remote frame	R/W
b31	GAFLIDE	IDE Select	0: Standard ID 1: Extended ID	R/W

GAFLID[28:0] Bits (ID Configuration)

These bits are used to set the ID field of the reception rule. The ID value set by these bits is compared with the ID of the received message during the acceptance filter processing.

GAFLLB Bit (Reception Rule Target Message Select)

When this bit is set to 0, data processing using the reception rule is performed when receiving messages transmitted from another CAN node.
When this bit is set to 1 when the mirror function is used, data processing using the reception rule is performed when the CAN node is receiving its own transmitted messages.

GAFLRTR Bit (RTR Select)

This bit is used to select the frame format (data frame or remote frame) of the reception rule. This bit is compared with the RTR bit in the received message during the acceptance filter processing.

GAFLIDE Bit (IDE Select)

This bit is used to select the ID format (standard ID or extended ID) of the reception rule. This bit is compared with the IDE bit in the received message during the acceptance filter processing.

35.2.14 Reception Rule Mask Registers (RSCAN0GAFLMj) (j = 0 to 15)

The RSCAN0GAFLMj registers control the settings for masking of the reception rule.
Modify the RSCAN0GAFLMj registers when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (enabling writing to the reception rule table) in global reset mode.

Address(es): RSCAN.RSCAN0GAFLM0 A007 8504h, RSCAN.RSCAN0GAFLM1 A007 8514h, RSCAN.RSCAN0GAFLM2 A007 8524h, RSCAN.RSCAN0GAFLM3 A007 8534h, RSCAN.RSCAN0GAFLM4 A007 8544h, RSCAN.RSCAN0GAFLM5 A007 8554h, RSCAN.RSCAN0GAFLM6 A007 8564h, RSCAN.RSCAN0GAFLM7 A007 8574h, RSCAN.RSCAN0GAFLM8 A007 8584h, RSCAN.RSCAN0GAFLM9 A007 8594h, RSCAN.RSCAN0GAFLM10 A007 85A4h, RSCAN.RSCAN0GAFLM11 A007 85B4h, RSCAN.RSCAN0GAFLM12 A007 85C4h, RSCAN.RSCAN0GAFLM13 A007 85D4h, RSCAN.RSCAN0GAFLM14 A007 85E4h, RSCAN.RSCAN0GAFLM15 A007 85F4h

GAFLIDM[28:0] Bits (ID Mask)

These bits are used to mask the corresponding ID bit of the reception rule.

GAFLRTRM Bit (RTR Mask)

This bit is used to mask the RTR bit of the reception rule.

GAFLIDEM Bit (IDE Mask)

When this bit is set to 1, filter processing is performed only for messages of the ID format specified by the GAFLIDE bit in the RSCAN0GAFLIDj register.
When this bit is cleared to 0, the IDs of all the received messages and the specified IDs are regarded as matched. To set the GAFLIDEM bit to 0, set the GAFLIDM[28:0] bits to all 0 at the same time.

35.2.15 Reception Rule Pointer 0 Registers (RSCAN0GAFLP0j) (j = 0 to 15)

The RSCAN0GAFLP0j registers control the minimum data length and labels for received messages and the settings for the reception buffer.

Modify the RSCAN0GAFLP0j registers when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (enabling writing to the reception rule table) in global reset mode.

Address(es): RSCAN.RSCAN0GAFLP00 A007 8508h, RSCAN.RSCAN0GAFLP01 A007 8518h, RSCAN.RSCAN0GAFLP02 A007 8528h, RSCAN.RSCAN0GAFLP03 A007 8538h, RSCAN.RSCAN0GAFLP04 A007 8548h, RSCAN.RSCAN0GAFLP05 A007 8558h, RSCAN.RSCAN0GAFLP06 A007 8568h, RSCAN.RSCAN0GAFLP07 A007 8578h, RSCAN.RSCAN0GAFLP08 A007 8588h, RSCAN.RSCAN0GAFLP09 A007 8598h, RSCAN.RSCAN0GAFLP010 A007 85A8h, RSCAN.RSCAN0GAFLP011 A007 85B8h, RSCAN.RSCAN0GAFLP012 A007 85C8h, RSCAN.RSCAN0GAFLP013 A007 85D8h, RSCAN.RSCAN0GAFLP014 A007 85E8h, RSCAN.RSCAN0GAFLP015 A007 85F8h

GAFLRMDP[6:0] Bits (Reception Buffer Number Select)

These bits are used to select the number of the reception buffer that stores received messages that have passed through the filter when the GAFLRMV bit is set to 1. Set these bits to a value smaller than the value set by the NRXMB[7:0] bits in the RSCAN0RMNB register.

GAFLRMV Bit (Reception Buffer Enable)

When this bit is set to 1, received messages that have passed through the filter are stored in the reception buffer selected by the GAFLRMDP[6:0] bits.

GAFLPTR[11:0] Bits (Reception Rule Label)

These bits are used to set a 12-bit label to be attached to messages that have passed through the filter. A label is attached when a message is stored in the reception buffer or the FIFO buffer.

GAFLDLC[3:0] Bits (Reception Rule DLC)

These bits are used to set the minimum data length necessary for receiving messages. If the data length of a message that is being filtered is equal to or larger than the value set by the GAFLDLC[3:0] bits, the message passes the DLC check. Setting these bits to 0000b disables the DLC check function allowing messages with any data length to pass the DLC check.

35.2.16 Reception Rule Pointer 1 Registers (RSCAN0GAFLP1j) (j = 0 to 15)

The RSCAN0GAFLP1j registers control the settings for the FIFO buffers for storing received messages that have passed through the filter.

Modify the RSCAN0GAFLP1j registers when the AFLDAE bit in the RSCAN0GAFLECTR register is set to 1 (enabling writing to the reception rule table) in global reset mode.

Address(es): RSCAN.RSCAN0GAFLP10 A007 850Ch, RSCAN.RSCAN0GAFLP11 A007 851Ch, RSCAN.RSCAN0GAFLP12 A007 852Ch, RSCAN.RSCAN0GAFLP13 A007 853Ch, RSCAN.RSCAN0GAFLP14 A007 854Ch, RSCAN.RSCAN0GAFLP15 A007 855Ch, RSCAN.RSCAN0GAFLP16 A007 856Ch, RSCAN.RSCAN0GAFLP17 A007 857Ch, RSCAN.RSCAN0GAFLP18 A007 858Ch, RSCAN.RSCAN0GAFLP19 A007 859Ch, RSCAN.RSCAN0GAFLP110 A007 85ACh, RSCAN.RSCAN0GAFLP111 A007 85BCh, RSCAN.RSCAN0GAFLP112 A007 85CCh, RSCAN.RSCAN0GAFLP113 A007 85DCh, RSCAN.RSCAN0GAFLP114 A007 85ECh, RSCAN.RSCAN0GAFLP115 A007 85FCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	GAFLFDPr [7:0]	Reception FIFO Buffer x Select	(Bit position = target reception FIFO buffer number x) 0: Reception FIFO buffer is not selected. 1: Reception FIFO buffer is selected.	R/W
b25 to b8	GAFLFDP [17:0]	Transmission/Reception FIFO Buffer k Select	(Bit position – 8 = target transmission/reception FIFO buffer number k) 0: Transmission/reception FIFO buffer is not selected. 1: Transmission/reception FIFO buffer is selected.	R/W
b31 to b26	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

GAFLFDP[17:0] and GAFLFDPr[7:0] Bits

These bits are used to specify FIFO buffers for storing received messages that have passed through the filter. Up to eight FIFO buffers are selectable. However, when the GAFLRMV bit in the RSCAN0GAFLP0j (j = 0 to 15) register is set to 1 (storing a message in the reception buffer), up to seven FIFO buffers can be selected. Only reception FIFO buffers and the transmission/reception FIFO buffer for which the CFM[1:0] bits in the RSCAN0CFCCk (k = 0 to 5) register are set to 00b (receive mode) or 10b (gateway mode) are selectable.

35.2.17 Reception Buffer Number Register (RSCAN0RMNB)

The RSCAN0RMNB register controls the number of reception buffers of the RSCAN module.
Modify the RSCAN0RMNB register in global reset mode.

Address(es): RSCAN.RSCAN0RMNB A007 80A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	NRXMB[7:0]	Reception Buffer Number Configuration	Set the number of reception buffers. Set a value between 0 to 32.	R/W
b31 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

NRXMB[7:0] Bits (Reception Buffer Number Configuration)

These bits are used to set the total number of reception buffers of the RSCAN module. The maximum value is 32 (16 for each channel).
Setting these bits all to 0 makes reception buffers unavailable.

35.2.18 Reception Buffer New Data Register 0 (RSCAN0RMND0)

The RSCAN0RMND0 register is a status register that indicates completion of the reception of messages by the reception buffer.

Write 0 to the RSCAN0RMND0 register in global operating mode or global test mode.

Address(es): RSCAN.RSCAN0RMND0 A007 80A8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	RMNSq_l (q = 15 to 0)															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	RMNSq_l	Reception Buffer Reception Complete Flag q_l (q = 15 to 0)	0: There is no new message in reception buffer q. 1: There is a new message in reception buffer q.	R/W
b31 to b16	RMNSq_h	Reception Buffer Reception Complete Flag q _h(q = 31 to 16)	0: There is no new message in reception buffer q. 1: There is a new message in reception buffer q.	R/W

RMNSq_l, RMNSq_h Flags (q = 0 to 15 for channel 0; q = 16 to 31 for channel 1)

Each RMNS flag is set to 1 when the processing for storing a message in the corresponding reception buffer starts.

To clear a flag to 0, the program must write 0 to the flag. Use a store instruction to write “0” to the flag and “1” to other flags. These bits cannot be set to 0 while a message is being stored. It takes ten clock cycles of PCLKD to store a message.

These flags are cleared to 0 in global reset mode.

35.2.19 Reception Buffer ID Registers (RSCAN0RMIDq) (q = 0 to 31)

The RSCAN0RMIDq registers are status registers that indicate the state of the ID and frame formats of the messages stored in the reception buffers (q = 0 to 15 for channel 0; q = 16 to 31 for channel 1).

Address(es): RSCAN.RSCAN0RMID0 A007 8600h, RSCAN.RSCAN0RMID1 A007 8610h, RSCAN.RSCAN0RMID2 A007 8620h, RSCAN.RSCAN0RMID3 A007 8630h, RSCAN.RSCAN0RMID4 A007 8640h, RSCAN.RSCAN0RMID5 A007 8650h, RSCAN.RSCAN0RMID6 A007 8660h, RSCAN.RSCAN0RMID7 A007 8670h, RSCAN.RSCAN0RMID8 A007 8680h, RSCAN.RSCAN0RMID9 A007 8690h, RSCAN.RSCAN0RMID10 A007 86A0h, RSCAN.RSCAN0RMID11 A007 86B0h, RSCAN.RSCAN0RMID12 A007 86C0h, RSCAN.RSCAN0RMID13 A007 86D0h, RSCAN.RSCAN0RMID14 A007 86E0h, RSCAN.RSCAN0RMID15 A007 86F0h, RSCAN.RSCAN0RMID16 A007 8700h, RSCAN.RSCAN0RMID17 A007 8710h, RSCAN.RSCAN0RMID18 A007 8720h, RSCAN.RSCAN0RMID19 A007 8730h, RSCAN.RSCAN0RMID20 A007 8740h, RSCAN.RSCAN0RMID21 A007 8750h, RSCAN.RSCAN0RMID22 A007 8760h, RSCAN.RSCAN0RMID23 A007 8770h, RSCAN.RSCAN0RMID24 A007 8780h, RSCAN.RSCAN0RMID25 A007 8790h, RSCAN.RSCAN0RMID26 A007 87A0h, RSCAN.RSCAN0RMID27 A007 87B0h, RSCAN.RSCAN0RMID28 A007 87C0h, RSCAN.RSCAN0RMID29 A007 87D0h, RSCAN.RSCAN0RMID30 A007 87E0h, RSCAN.RSCAN0RMID31 A007 87F0h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	RMID[28:0]	Reception Buffer ID Data	These bits contain the standard ID or extended ID of the received messages. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.	R
b29	—	Reserved	This bit is read as 0.	R
b30	RMRTR	Reception Buffer RTR	0: Data frame 1: Remote frame	R
b31	RMIDE	Reception Buffer IDE	0: Standard ID 1: Extended ID	R

RMID[28:0] Bits (Reception Buffer ID Data)

These bits contain the ID of the messages stored in the reception buffers.

RMRTR Bit (Reception Buffer RTR)

This bit indicates the frame format (data frame or remote frame) of the messages stored in the reception buffers.

RMIDE Bit (Reception Buffer IDE)

This bit indicates the ID format (standard ID or extended ID) of the messages stored in the reception buffers.

35.2.20 Reception Buffer Pointer Registers (RSCAN0RMPTRq) (q = 0 to 31)

The RSCAN0RMPTRq registers are status registers that indicate the data length, label information, and timestamp value of the messages stored in the reception buffers (q = 0 to 15 for channel 0; q = 16 to 31 for channel 1).

Address(es): RSCAN.RSCAN0RMPTR0 A007 8604h, RSCAN.RSCAN0RMPTR1 A007 8614h, RSCAN.RSCAN0RMPTR2 A007 8624h, RSCAN.RSCAN0RMPTR3 A007 8634h, RSCAN.RSCAN0RMPTR4 A007 8644h, RSCAN.RSCAN0RMPTR5 A007 8654h, RSCAN.RSCAN0RMPTR6 A007 8664h, RSCAN.RSCAN0RMPTR7 A007 8674h, RSCAN.RSCAN0RMPTR8 A007 8684h, RSCAN.RSCAN0RMPTR9 A007 8694h, RSCAN.RSCAN0RMPTR10 A007 86A4h, RSCAN.RSCAN0RMPTR11 A007 86B4h, RSCAN.RSCAN0RMPTR12 A007 86C4h, RSCAN.RSCAN0RMPTR13 A007 86D4h, RSCAN.RSCAN0RMPTR14 A007 86E4h, RSCAN.RSCAN0RMPTR15 A007 86F4h, RSCAN.RSCAN0RMPTR16 A007 8704h, RSCAN.RSCAN0RMPTR17 A007 8714h, RSCAN.RSCAN0RMPTR18 A007 8724h, RSCAN.RSCAN0RMPTR19 A007 8734h, RSCAN.RSCAN0RMPTR20 A007 8744h, RSCAN.RSCAN0RMPTR21 A007 8754h, RSCAN.RSCAN0RMPTR22 A007 8764h, RSCAN.RSCAN0RMPTR23 A007 8774h, RSCAN.RSCAN0RMPTR24 A007 8784h, RSCAN.RSCAN0RMPTR25 A007 8794h, RSCAN.RSCAN0RMPTR26 A007 87A4h, RSCAN.RSCAN0RMPTR27 A007 87B4h, RSCAN.RSCAN0RMPTR28 A007 87C4h, RSCAN.RSCAN0RMPTR29 A007 87D4h, RSCAN.RSCAN0RMPTR30 A007 87E4h, RSCAN.RSCAN0RMPTR31 A007 87F4h

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	RMTS[15:0]	Reception Buffer Timestamp Data	Timestamp value of the received messages	R
b27 to b16	RMPTR[11:0]	Reception Buffer Label Data	Label information of the received messages	R
b31 to b28	RMDLC[3:0]	Reception Buffer DLC Data	b31 b30 b29 b28 0 0 0 0: No data byte 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes	R

RMTS[15:0] Bits (Reception Buffer Timestamp Data)

These bits indicate the timestamp value of the message stored in the reception buffer.

RMPTR[11:0] Bits (Reception Buffer Label Data)

These bits indicate the label information of the message stored in the reception buffer.

RMDLC[3:0] Bits (Reception Buffer DLC Data)

These bits indicate the data length of the message stored in the reception buffer.

35.2.21 Reception Buffer Data Field 0 Registers (RSCAN0RMDF0q) (q = 0 to 31)

The RSCAN0RMDF0q registers are data registers that hold the values in the reception buffers (q = 0 to 15 for channel 0; q = 16 to 31 for channel 1).

When the value of the RMDLC[3:0] bits in the RSCAN0RMPTRq register is less than 1000b, data bytes for which no value is set are read as 00h.

Address(es): RSCAN.RSCAN0RMDF00 A007 8608h, RSCAN.RSCAN0RMDF01 A007 8618h, RSCAN.RSCAN0RMDF02 A007 8628h, RSCAN.RSCAN0RMDF03 A007 8638h, RSCAN.RSCAN0RMDF04 A007 8648h, RSCAN.RSCAN0RMDF05 A007 8658h, RSCAN.RSCAN0RMDF06 A007 8668h, RSCAN.RSCAN0RMDF07 A007 8678h, RSCAN.RSCAN0RMDF08 A007 8688h, RSCAN.RSCAN0RMDF09 A007 8698h, RSCAN.RSCAN0RMDF010 A007 86A8h, RSCAN.RSCAN0RMDF011 A007 86B8h, RSCAN.RSCAN0RMDF012 A007 86C8h, RSCAN.RSCAN0RMDF013 A007 86D8h, RSCAN.RSCAN0RMDF014 A007 86E8h, RSCAN.RSCAN0RMDF015 A007 86F8h, RSCAN.RSCAN0RMDF016 A007 8708h, RSCAN.RSCAN0RMDF017 A007 8718h, RSCAN.RSCAN0RMDF018 A007 8728h, RSCAN.RSCAN0RMDF019 A007 8738h, RSCAN.RSCAN0RMDF020 A007 8748h, RSCAN.RSCAN0RMDF021 A007 8758h, RSCAN.RSCAN0RMDF022 A007 8768h, RSCAN.RSCAN0RMDF023 A007 8778h, RSCAN.RSCAN0RMDF024 A007 8788h, RSCAN.RSCAN0RMDF025 A007 8798h, RSCAN.RSCAN0RMDF026 A007 87A8h, RSCAN.RSCAN0RMDF027 A007 87B8h, RSCAN.RSCAN0RMDF028 A007 87C8h, RSCAN.RSCAN0RMDF029 A007 87D8h, RSCAN.RSCAN0RMDF030 A007 87E8h, RSCAN.RSCAN0RMDF031 A007 87F8h

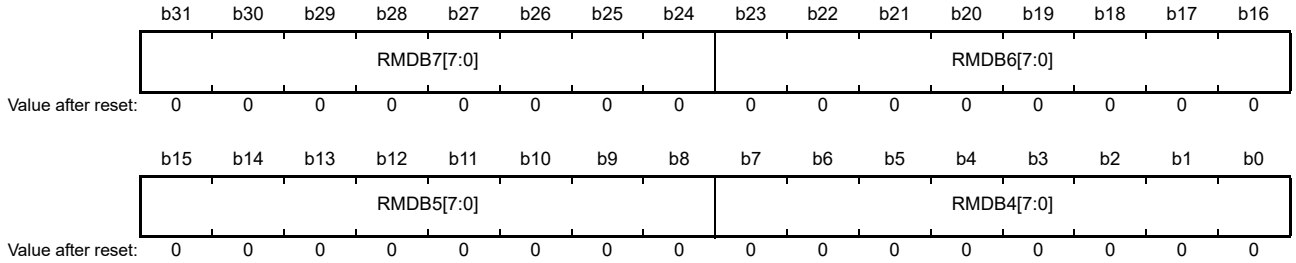
b31 to b24	RMDB3[7:0]	Reception Buffer Data Byte 3		R

35.2.22 Reception Buffer Data Field 1 Registers (RSCAN0RMDF1q) (q = 0 to 31)

The RSCAN0RMDF1q registers are data registers that hold the values in the reception buffers (q = 0 to 15 for channel 0; q = 16 to 31 for channel 1).

When the value of the RMDLC[3:0] bits in the RSCAN0RMPTRq register is less than 1000b, data bytes for which no value is set are read as 00h.

Address(es): RSCAN.RSCAN0RMDF10 A007 860Ch, RSCAN.RSCAN0RMDF11 A007 861Ch, RSCAN.RSCAN0RMDF12 A007 862Ch, RSCAN.RSCAN0RMDF13 A007 863Ch, RSCAN.RSCAN0RMDF14 A007 864Ch, RSCAN.RSCAN0RMDF15 A007 865Ch, RSCAN.RSCAN0RMDF16 A007 866Ch, RSCAN.RSCAN0RMDF17 A007 867Ch, RSCAN.RSCAN0RMDF18 A007 868Ch, RSCAN.RSCAN0RMDF19 A007 869Ch, RSCAN.RSCAN0RMDF110 A007 86ACh, RSCAN.RSCAN0RMDF111 A007 86BCh, RSCAN.RSCAN0RMDF112 A007 86CCh, RSCAN.RSCAN0RMDF113 A007 86DCh, RSCAN.RSCAN0RMDF114 A007 86ECh, RSCAN.RSCAN0RMDF115 A007 86FCh, RSCAN.RSCAN0RMDF116 A007 870Ch, RSCAN.RSCAN0RMDF117 A007 871Ch, RSCAN.RSCAN0RMDF118 A007 872Ch, RSCAN.RSCAN0RMDF119 A007 873Ch, RSCAN.RSCAN0RMDF120 A007 874Ch, RSCAN.RSCAN0RMDF121 A007 875Ch, RSCAN.RSCAN0RMDF122 A007 876Ch, RSCAN.RSCAN0RMDF123 A007 877Ch, RSCAN.RSCAN0RMDF124 A007 878Ch, RSCAN.RSCAN0RMDF125 A007 879Ch, RSCAN.RSCAN0RMDF126 A007 87ACh, RSCAN.RSCAN0RMDF127 A007 87BCh, RSCAN.RSCAN0RMDF128 A007 87CCh, RSCAN.RSCAN0RMDF129 A007 87DCh, RSCAN.RSCAN0RMDF130 A007 87ECh, RSCAN.RSCAN0RMDF131 A007 87FCh



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	RMDB4[7:0]	Reception Buffer Data Byte 4	Values of messages stored in the corresponding reception buffer can be read from these bits.	R
b15 to b8	RMDB5[7:0]	Reception Buffer Data Byte 5		R
b23 to b16	RMDB6[7:0]	Reception Buffer Data Byte 6		R
b31 to b24	RMDB7[7:0]	Reception Buffer Data Byte 7		R

35.2.23 Reception FIFO Buffer Configuration and Control Registers (RSCAN0RFCCx) (x = 0 to 7)

The RSCAN0RFCCx registers control reception FIFO buffer interrupts and the number of reception FIFO buffer stages.

Address(es): RSCAN.RSCAN0RFCC0 A007 80B8h, RSCAN.RSCAN0RFCC1 A007 80BCh, RSCAN.RSCAN0RFCC2 A007 80C0h, RSCAN.RSCAN0RFCC3 A007 80C4h, RSCAN.RSCAN0RFCC4 A007 80C8h, RSCAN.RSCAN0RFCC5 A007 80CCh, RSCAN.RSCAN0RFCC6 A007 80D0h, RSCAN.RSCAN0RFCC7 A007 80D4h

b11	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b12	RFIM	Receive FIFO Interrupt Source Select	0: An interrupt occurs when the condition set by the RFIGCV[2:0] bits is met. 1: An interrupt occurs each time a message has been received.	R/W
b15 to b13	RFIGCV[2:0]	Receive FIFO Interrupt Request Timing Select	b15 b14 b13 0 0 0: When FIFO is 1/8 full. 0 0 1: When FIFO is 2/8 full. 0 1 0: When FIFO is 3/8 full. 0 1 1: When FIFO is 4/8 full. 1 0 0: When FIFO is 5/8 full. 1 0 1: When FIFO is 6/8 full. 1 1 0: When FIFO is 7/8 full. 1 1 1: When FIFO is full.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

RFE Bit (Reception FIFO Buffer Enable)

Setting the RFE bit to 1 makes reception FIFO buffers available. Clearing this bit to 0 sets the RFEMP flag in the RSCAN0RFSTSx register to 1 (buffer empty). Modify this bit in global operating mode or global test mode.

RFIE Bit (Receive FIFO Interrupt Enable)

Setting the RFIE bit to 1 enables receive FIFO interrupts. Modify this bit when the RFE bit set to 0 (no reception FIFO buffer is used).

RFDC[2:0] Bits (Reception FIFO Buffer Depth Configuration)

These bits are used to select the number of messages that can be stored in a single reception FIFO buffer. When these bits are set to 000b, no reception FIFO buffer should be used. Modify these bits only in global reset mode.

RFIM Bit (Receive FIFO Interrupt Source Select)

This bit is used to select a FIFO interrupt source. Modify this bit only in global reset mode.

RFIGCV[2:0] Bits (Receive FIFO Interrupt Request Timing Select)

These bits are used to specify the number of received messages for generating a receive FIFO interrupt request when the RFIM bit is set to 0 with a fraction for the total number of buffers (the setting of RFDC[2:0]).
When the RFDC[2:0] bits are set to 001b (4 messages), set the RFIGCV[2:0] bits to 001b, 011b, 101b, or 111b. Modify these bits only in global reset mode.

35.2.24 Reception FIFO Buffer Status Registers (RSCAN0RFSTSx) (x = 0 to 7)

The RSCAN0RFSTSx registers are status registers that indicate whether the reception FIFO buffers are empty, the number of unread messages, etc.

Address(es): RSCAN.RSCAN0RFSTS0 A007 80D8h, RSCAN.RSCAN0RFSTS1 A007 80DCh, RSCAN.RSCAN0RFSTS2 A007 80E0h, RSCAN.RSCAN0RFSTS3 A007 80E4h, RSCAN.RSCAN0RFSTS4 A007 80E8h, RSCAN.RSCAN0RFSTS5 A007 80ECh, RSCAN.RSCAN0RFSTS6 A007 80F0h, RSCAN.RSCAN0RFSTS7 A007 80F4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	RFMC[7:0]								—	—	—	—	RFIF	RFMLT	RFFLL	RFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	RFEMP	Reception FIFO Buffer Empty Status Flag	0: The reception FIFO buffer contains unread message. 1: The reception FIFO buffer contains no unread messages (buffer empty).	R
b1	RFFLL	Reception FIFO Buffer Full Status Flag	0: The reception FIFO buffer is not full. 1: The reception FIFO buffer is full.	R
b2	RFMLT	Receive FIFO Message Lost Flag	0: No receive FIFO message is lost. 1: A receive FIFO message is lost.	R/W *1
b3	RFIF	Receive FIFO Interrupt Request Flag	0: No receive FIFO interrupt request is present. 1: A receive FIFO interrupt request is present.	R/W *1
b7 to b4	—	Reserved	These bits are read as 0.	R
b15 to b8	RFMC[7:0]	Receive FIFO Unread Message Counter	The number of unread messages stored in the reception FIFO buffer is displayed.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

RFEMP Flag (Reception FIFO Buffer Empty Status Flag)

This flag is set to 1 when all messages in the reception FIFO buffer have been read. This flag is also set to 1 when the RFE bit in the RSCAN0RFCCx register is 0 or in global reset mode.

This flag is cleared to 0 when even a single received message has been stored in the reception FIFO buffer.

RFFLL Flag (Reception FIFO Buffer Full Status Flag)

This flag is set to 1 when the number of messages stored in the reception FIFO buffer matches the FIFO buffer depth set by the RFDC[2:0] bits in the RSCAN0RFCCx register.

If the number of messages stored in the reception FIFO buffer becomes smaller than the FIFO buffer depth set by the RFDC[2:0] bits, this flag is cleared to 0. This flag is also cleared to 0 when the RFE bit in the RSCAN0RFCCx register is set to 0 (no reception FIFO buffer is used) or in global reset mode.

RFMLT Flag (Receive FIFO Message Lost Flag)

This flag is set to 1 when an attempt is made to store a new message while the reception FIFO buffer is full. In this case, the new message is discarded.
This flag is cleared to 0 in global reset mode or by writing 0 to this flag.
Modify this bit in global operating mode or global test mode.
To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFIF Flag (Receive FIFO Interrupt Request Flag)

This flag is set to 1 when the receive FIFO interrupt request generation conditions set by the RFIGCV[2:0] bits and the RFIM bit in the RSCAN0RFCCx register are met. This flag is cleared to 0 in global reset mode or by writing 0 to this flag. Modify this bit in global operating mode or global test mode.
To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

RFMC[7:0] Flag (Receive FIFO Unread Message Counter)

This flag indicates the number of unread messages in the reception FIFO buffer. These flags become 00h when the RFE bit in the RSCAN0RFCCx register is set to 0.

35.2.25 Reception FIFO Buffer Pointer Control Registers (RSCAN0RFPCTRx) (x = 0 to 7)

The RSCAN0RFPCTRx registers control the pointer to the reception FIFO buffer.

Address(es): RSCAN.RSCAN0RFPCTR0 A007 80F8h, RSCAN.RSCAN0RFPCTR1 A007 80FCh, RSCAN.RSCAN0RFPCTR2 A007 8100h, RSCAN.RSCAN0RFPCTR3 A007 8104h, RSCAN.RSCAN0RFPCTR4 A007 8108h, RSCAN.RSCAN0RFPCTR5 A007 810Ch, RSCAN.RSCAN0RFPCTR6 A007 8110h, RSCAN.RSCAN0RFPCTR7 A007 8114h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	RFPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	RFPC[7:0]	Receive FIFO Pointer Control	When these bits are set to FFh, the read pointer moves to the next unread message in the reception FIFO buffer.	W
b31 to b8	—	Reserved	The write value should be 0.	W

RFPC[7:0] Bits (Receive FIFO Pointer Control)

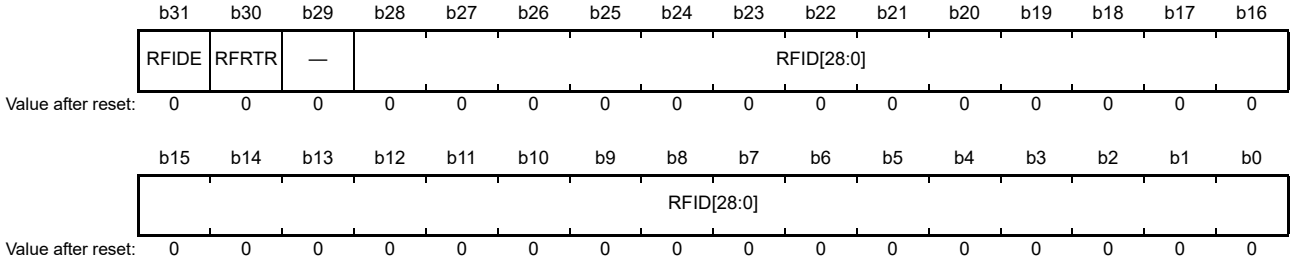
When the RFPC[7:0] bits are set to FFh, the read pointer moves to the next unread message in the reception FIFO buffer. At this time, the RFMC[7:0] (receive FIFO unread message counter) value in the RSCAN0RFSTSx register is decremented. Read the RSCAN0RFID, RSCAN0RFPTR, RSCAN0RFDF0, and RSCAN0RFDF1 registers to read messages in the reception FIFO buffer, and then write FFh to the RFPC[7:0] bits.

When writing FFh to these bits, make sure that the RFE bit in the RSCAN0RFCCx register is set to 1 (reception FIFO buffers are used) and the RFEMP flag in the RSCAN0RFSTSx register is 0 (the reception FIFO buffer contains unread messages).

35.2.26 Reception FIFO Buffer Access ID Registers (RSCAN0RFIDx) (x = 0 to 7)

The RSCAN0RFIDx registers are status registers that indicate the state of the ID and frame formats of the messages stored in the reception FIFO buffers.

Address(es): RSCAN.RSCAN0RFID0 A007 8E00h, RSCAN.RSCAN0RFID1 A007 8E10h, RSCAN.RSCAN0RFID2 A007 8E20h, RSCAN.RSCAN0RFID3 A007 8E30h, RSCAN.RSCAN0RFID4 A007 8E40h, RSCAN.RSCAN0RFID5 A007 8E50h, RSCAN.RSCAN0RFID6 A007 8E60h, RSCAN.RSCAN0RFID7 A007 8E70h



Bit	Symbol	Bit Name	Description	R/W
b28 to b0	RFID[28:0]	Reception FIFO Buffer ID Data	The standard ID or extended ID of received message can be read. Read bits b10 to b0 for standard ID. Bits b28 to b11 are read as 0.	R
b29	—	Reserved	This bit is read as 0.	R
b30	RFRTR	Reception FIFO Buffer RTR	0: Data frame 1: Remote frame	R
b31	RFIDE	Reception FIFO Buffer IDE	0: Standard ID 1: Extended ID	R

RFID[28:0] Bits (Reception FIFO Buffer ID Data)

These bits indicate the ID of the messages stored in the reception FIFO buffers.

RFRTR Bit (Reception FIFO Buffer RTR)

This bit indicates the frame format (data frame or remote frame) of the messages stored in the reception FIFO buffers.

RFIDE Bit (Reception FIFO Buffer IDE)

This bit indicates the ID format (standard ID or extended ID) of the messages stored in the reception FIFO buffers.

35.2.27 Reception FIFO Buffer Access Pointer Registers (RSCAN0RFPTRx) (x = 0 to 7)

The RSCAN0RFPTRx registers are status registers that indicate the data length, label information, and timestamp value of the messages stored in the reception FIFO buffers.

Address(es): RSCAN.RSCAN0RFPTR0 A007 8E04h, RSCAN.RSCAN0RFPTR1 A007 8E14h, RSCAN.RSCAN0RFPTR2 A007 8E24h, RSCAN.RSCAN0RFPTR3 A007 8E34h, RSCAN.RSCAN0RFPTR4 A007 8E44h, RSCAN.RSCAN0RFPTR5 A007 8E54h, RSCAN.RSCAN0RFPTR6 A007 8E64h, RSCAN.RSCAN0RFPTR7 A007 8E74h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	RFDLC[3:0]				RFPTR[11:0]

	RFTS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	RFTS[15:0]	Reception FIFO Buffer Timestamp Data	Timestamp value of the received messages can be read.	R
b27 to b16	RFPTR[11:0]	Reception FIFO Buffer Label Data	Label information of the received messages can be read.	R
b31 to b28	RFDLC[3:0]	Reception FIFO Buffer DLC Data	b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes	R

RFTS[15:0] Bits (Reception FIFO Buffer Timestamp Data)

These bits contain the timestamp value of the messages stored in the reception FIFO buffers.

RFPTR[11:0] Bits (Reception FIFO Buffer Label Data)

These bits contain the label information of the messages stored in the reception FIFO buffers.

RFDLC[3:0] Bits (Reception FIFO Buffer DLC Data)

These bits contain the data length of the messages stored in the reception FIFO buffers.

35.2.28 Reception FIFO Buffer Access Data Field 0 Registers (RSCAN0RFDF0x) (x = 0 to 7)

The RSCAN0RFDF0x registers are data registers that hold the values in the reception FIFO buffers.
When the value of the RMDLC[3:0] bits in the RSCAN0RFPTRx register is less than 1000b, data bytes for which no value is set are read as 00h.

Address(es): RSCAN.RSCAN0RFDF00 A007 8E08h, RSCAN.RSCAN0RFDF01 A007 8E18h, RSCAN.RSCAN0RFDF02 A007 8E28h, RSCAN.RSCAN0RFDF03 A007 8E38h, RSCAN.RSCAN0RFDF04 A007 8E48h, RSCAN.RSCAN0RFDF05 A007 8E58h, RSCAN.RSCAN0RFDF06 A007 8E68h, RSCAN.RSCAN0RFDF07 A007 8E78h

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	RFDB0[7:0]	Reception FIFO Buffer Data Byte 0	Values of messages stored in the corresponding reception FIFO buffer can be read from these bits.	R
b15 to b8	RFDB1[7:0]	Reception FIFO Buffer Data Byte 1		R
b23 to b16	RFDB2[7:0]	Reception FIFO Buffer Data Byte 2		R
b31 to b24	RFDB3[7:0]	Reception FIFO Buffer Data Byte 3		R

35.2.29 Reception FIFO Buffer Access Data Field 1 Registers (RSCAN0RFDF1x) (x = 0 to 7)

The RSCAN0RFDF1x registers are data registers that hold the values in the reception FIFO buffers.
When the value of the RMDLC[3:0] bits in the RSCAN0RFPTRx register is less than 1000b, data bytes for which no value is set are read as 00h.

Address(es): RSCAN.RSCAN0RFDF10 A007 8E0Ch, RSCAN.RSCAN0RFDF11 A007 8E1Ch, RSCAN.RSCAN0RFDF12 A007 8E2Ch, RSCAN.RSCAN0RFDF13 A007 8E3Ch, RSCAN.RSCAN0RFDF14 A007 8E4Ch, RSCAN.RSCAN0RFDF15 A007 8E5Ch, RSCAN.RSCAN0RFDF16 A007 8E6Ch, RSCAN.RSCAN0RFDF17 A007 8E7Ch

b15 to b8	RFDB5[7:0]	Reception FIFO Buffer Data Byte 5		R
b23 to b16	RFDB6[7:0]	Reception FIFO Buffer Data Byte 6		R
b31 to b24	RFDB7[7:0]	Reception FIFO Buffer Data Byte 7		R

35.2.30 Transmission/Reception FIFO Buffer Configuration and Control Registers k (RSCAN0CFCCk) (k = 0 to 5)

The RSCAN0CFCCk registers control the settings for the transmission/reception FIFO buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1).

Address(es): RSCAN.RSCAN0CFCC0 A007 8118h, RSCAN.RSCAN0CFCC1 A007 811Ch, RSCAN.RSCAN0CFCC2 A007 8120h, RSCAN.RSCAN0CFCC3 A007 8124h, RSCAN.RSCAN0CFCC4 A007 8128h, RSCAN.RSCAN0CFCC5 A007 812Ch

CFE Bit (Transmission/Reception FIFO Buffer Enable)

Setting this bit to 1 makes transmission/reception FIFO buffers available.

When this bit is set to 0 in transmission mode or gateway mode, if a message in the transmission/reception FIFO buffer is being transmitted or will be transmitted next, the transmission/reception FIFO buffer becomes empty after completion of transmission of that message, or upon detection of a CAN bus error, or arbitration-lost. In other cases or in reception mode, the transmission/reception FIFO buffer becomes empty immediately.

This bit is cleared to 0 when the following conditions are met.

- Reception mode: Global reset mode
- Transmission mode or gateway mode: Channel reset mode

Modify this bit in the following mode.

- Reception mode: Global operating mode or global test mode
- Transmission mode or gateway mode: Channel communication mode or channel halt mode

CFRXIE Bit (Transmit/Receive FIFO Receive Interrupt Enable)

When this bit is set to 1 and the CFRXIF flag in the RSCAN0CFSTSk register is set to 1, a transmit/receive FIFO receive interrupt request is generated.

Modify this bit with the CFE bit set to 0.

CFTXIE Bit (Transmit/Receive FIFO Transmit Interrupt Enable)

When this bit is set to 1 and the CFTXIF flag in the RSCAN0CFSTSk register is set to 1, a transmit/receive FIFO transmit interrupt request is generated.

Modify this bit with the CFE bit set to 0 (no transmission/reception FIFO buffer is used).

CFDC[2:0] Bits (Transmission/Reception FIFO Buffer Depth Configuration)

These bits are used to set the number of messages that can be stored in a single transmission/reception FIFO buffer.

When these bits are set to 000b, do not use a transmission/reception FIFO buffer. Modify these bits only in global reset mode.

CFIM Bit (Transmit/Receive FIFO Interrupt Source Select)

This bit is used to select a transmit/receive FIFO interrupt source. Modify this bit only in global reset mode.

CFIGCV[2:0] Bits (Transmit/Receive FIFO Receive Interrupt Request Timing Select)

These bits are used to specify the number of received messages for generating a transmit/receive FIFO receive interrupt request when the CFM[1:0] bits are set to 00b (reception mode) or 10b (gateway mode) and the CFIM bit is set to 0 with a fraction for the total number of buffers (the setting of CFDC[2:0]).
When the CFDC[2:0] bits are set to 001b (4 messages), set the CFIGCV[2:0] bits to 001b, 011b, 101b, or 111b.
Modify these bits only in global reset mode.

CFM[1:0] Bits (Transmit/Receive FIFO Mode Select)

These bits are used to select transmit/receive FIFO mode. Modify these bits only in global reset mode.

CFITSS Bit (Transmit/Receive FIFO Interval Timer Clock Source Select)

When this bit is 0, the clock selected by the CFITR bit is the count source of the interval timer.
When this bit is 1, the bit time clock of the channel to which the FIFO is linked is the count source of the interval timer.
Modify this bit while the CFE bit is set to 0 (no transmission/reception FIFO buffer is used).

CFITR Bit (Transmit/Receive FIFO Interval Timer Resolution Select)

This bit is enabled when the CFITSS bit is 0.
When this bit is 0, the interval timer clock source is the PCLKD/2 clock divided by the value of the ITRCP[15:0] bits in the RSCAN0GCFG register.
When this bit is 1, the interval timer clock source is the PCLKD/2 clock divided by (the value of the ITRCP[15:0] bits in the RSCAN0GCFG register × 10).
Modify this bit while the CFE bit is set to 0 (no transmission/reception FIFO buffer is used).

CFTML[3:0] Bits (Transmission Buffer Link Configuration)

These bits are used to set the number of transmission buffer on the channel which will be linked to transmission/reception FIFO buffer k when the CFM[1:0] bits are set to 01b (transmission mode) or 10b (gateway mode). There are three transmission/reception FIFO buffers per channel (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1). Table 35.4 lists the actual transmission buffer numbers p linked to FIFO buffers k.

See section 35.6, Transmission Functions, for operations of transmission/reception FIFO buffers k and transmission buffers p.

Setting the CFDC[2:0] bits to 001b or more enables the setting of the CFTML[3:0] bits.

Do not link to any transmission buffer which is already allocated to a transmission queue on the identical channel or to another transmission/reception FIFO buffer. Modify these bits only in global reset mode.

Table 35.4 Settings of the CFTML[3:0] Bits and Linking of Transmission Buffers p to Transmission/Reception FIFO Buffers k

Settings of CFTML[3:0] Bits (setting for each transmission/reception FIFO buffer k)	Transmission Buffers p Linked to Transmission/Reception FIFO Buffers (p = 0 to 31)	
	Channel 0 (m = 0)	Channel 1 (m = 1)
0000b	Transmission buffer 0	Transmission buffer 16
0001b	Transmission buffer 1	Transmission buffer 17
0010b	Transmission buffer 2	Transmission buffer 18
0011b	Transmission buffer 3	Transmission buffer 19
0100b	Transmission buffer 4	Transmission buffer 20
0101b	Transmission buffer 5	Transmission buffer 21
0110b	Transmission buffer 6	Transmission buffer 22
0111b	Transmission buffer 7	Transmission buffer 23
1000b	Transmission buffer 8	Transmission buffer 24
1001b	Transmission buffer 9	Transmission buffer 25
1010b	Transmission buffer 10	Transmission buffer 26
1011b	Transmission buffer 11	Transmission buffer 27
1100b	Transmission buffer 12	Transmission buffer 28
1101b	Transmission buffer 13	Transmission buffer 29
1110b	Transmission buffer 14	Transmission buffer 30
1111b	Transmission buffer 15	Transmission buffer 31

CFITT[7:0] Bits (Message Transmission Interval Configuration)

These bits are used to set a message transmission interval when transmitting messages continuously from a transmission/reception FIFO buffer whose CFM[1:0] bits are set to 01b (transmission mode) or 10b (gateway mode).

Clear the CFE bit to 0 (no transmission/reception FIFO buffer is used) before modifying the CFITT[7:0] bits.

35.2.31 Transmission/Reception FIFO Buffer Status Registers (RSCAN0CFSTSk) (k = 0 to 5)

The RSCAN0CFSTSk registers are status registers that indicate the state of the transmission/reception FIFO buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1).

Address(es): RSCAN.RSCAN0CFSTS0 A007 8178h, RSCAN.RSCAN0CFSTS1 A007 817Ch, RSCAN.RSCAN0CFSTS2 A007 8180h, RSCAN.RSCAN0CFSTS3 A007 8184h, RSCAN.RSCAN0CFSTS4 A007 8188h, RSCAN.RSCAN0CFSTS5 A007 818Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CFMC[7:0]								—	—	—	CFTXIF	CFRXIF	CFMLT	CFFLL	CFEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	CFEMP	Transmission/Reception FIFO Buffer Empty Status Flag	0: The transmission/reception FIFO buffer contains messages. 1: The transmission/reception FIFO buffer contains no message (buffer empty).	R
b1	CFFLL	Transmission/Reception FIFO Buffer Full Status Flag	0: The transmission/reception FIFO buffer is not full. 1: The transmission/reception FIFO buffer is full.	R
b2	CFMLT	Transmit/Receive FIFO Message Lost Flag	0: No transmit/receive FIFO message is lost. 1: A transmit/receive FIFO message is lost.	R/W *1
b3	CFRXIF	Transmit/Receive FIFO Receive Interrupt Request Flag	0: No transmit/receive FIFO receive interrupt request is present. 1: A transmit/receive FIFO receive interrupt request is present.	R/W *1
b4	CFTXIF	Transmit/Receive FIFO Transmit Interrupt Request Flag	0: No transmit/receive FIFO transmit interrupt request is present. 1: A transmit/receive FIFO transmit interrupt request is present.	R/W *1
b7 to b5	—	Reserved	These bits are read as 0.	R
b15 to b8	CFMC[7:0]	Transmit/Receive FIFO Message Counter	The number of messages stored in the transmission/ reception FIFO buffer.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

CFEMP Flag (Transmission/Reception FIFO Buffer Empty Status Flag)

The CFEMP flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00b: All messages have been read, or in global reset mode
- When the CFM[1:0] bits are set to 01b or 10b: All messages have been transmitted, or in channel reset mode
- When the CFE bit is 0 (no transmission/reception FIFO buffer is used): Not in the transmission abort

The CFEMP flag is cleared to 0 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00b or 10b: At least one received message has been stored in the transmission/ reception FIFO buffer.
- When the CFM[1:0] bits are set to 01b: A value of FFh has been written to the RSCAN0CFPCTRk register after data was written to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers.

CFFLL Flag (Transmission/Reception FIFO Buffer Full Status Flag)

The CFFLL flag is set to 1 when any of the following conditions is met.

- When the number of messages stored in the transmission/reception FIFO buffer matches the FIFO buffer depth set by the CFDC[2:0] bits in the RSCAN0CFCCk register.

The CFFLL flag is cleared to 0 when any of the following conditions is met.

- When the number of messages stored in the transmission/reception FIFO buffer becomes smaller than the FIFO buffer depth set by the CFDC[2:0] bits.
- When the CFE bit in the RSCAN0CFCCk register is 0 (no transmission/reception FIFO buffer is used): When not in the transmission abort
- When the CFM[1:0] bits are set to 00b: In global reset mode
  When the CFM[1:0] bits are set to 01b or 10b: In channel reset mode

CFMLT Flag (Transmit/Receive FIFO Message Lost Flag)

The CFMLT flag is set to 1 when any of the following conditions is met.

- When an attempt is made to store a new message while the transmission/reception FIFO buffer is full. In this case, the new message is discarded.

The CFMLT flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFMLT flag
- When the CFM[1:0] bits are set to 00b: In global reset mode
- When the CFM[1:0] bits are set to 01b or 10b: In channel reset mode

Write 0 to this flag in global operating mode or global test mode

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFRXIF Flag (Transmit/Receive FIFO Receive Interrupt Request Flag)

The CFRXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 00b or 10b, and the factor selected by the CFIM bit in the RSCAN0CFCCk register occurs

The CFRXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFRXIF flag
- When the CFM[1:0] bits are set to 00b: In global reset mode
- When the CFM[1:0] bits are set to 01b or 10b: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFTXIF Flag (Transmit/Receive FIFO Transmit Interrupt Request Flag)

The CFTXIF flag is set to 1 when any of the following conditions is met.

- When the CFM[1:0] bits are set to 01b or 10b, and the factor selected by the CFIM bit in the RSCAN0CFCCk register occurs

The CFTXIF flag is cleared to 0 when any of the following conditions is met.

- When 0 is written to the CFTXIF flag
- When the CFM[1:0] bits are set to 00b: In global reset mode
- When the CFM[1:0] bits are set to 01b or 10b: In channel reset mode

Write 0 to this flag in global operating mode or global test mode.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared. When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

CFMC[7:0] Bits (Transmit/Receive FIFO Message Counter)

The CFMC[7:0] bits indicate the following values that depend on the setting of the CFM[1:0] bits in the RSCAN0CFCCk register.

- When CFM[1:0] value is 01b (transmission mode): Number of untransmitted messages in the buffer
- When CFM[1:0] value is 00b (reception mode): Number of unread received messages in the buffer
- When CFM[1:0] value is 10b (gateway mode): Number of untransmitted received messages in the buffer

These bits are cleared to 0 when any of the following conditions is met.

- When CFM[1:0] value is 00b: In global reset mode
- When CFM[1:0] value is 01b or 10b: In channel reset mode

35.2.32 Transmission/Reception FIFO Buffer Pointer Control Registers (RSCAN0CFPCTRk) (k = 0 to 5)

The RSCAN0CFPCTRk registers control the pointers to the transmission/reception FIFO buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1).

Address(es): RSCAN.RSCAN0CFPCTR0 A007 81D8h, RSCAN.RSCAN0CFPCTR1 A007 81DCh, RSCAN.RSCAN0CFPCTR2 A007 81E0h, RSCAN.RSCAN0CFPCTR3 A007 81E4h, RSCAN.RSCAN0CFPCTR4 A007 81E8h, RSCAN.RSCAN0CFPCTR5 A007 81ECh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	CFPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	CFPC[7:0]	Transmit/Receive FIFO Pointer Control	• Reception mode: Writing FFh to these bits moves the read pointer to the next unread message in the transmission/reception FIFO buffer. • Transmission mode: Writing FFh to these bits moves the write pointer to the next stage of the transmission/reception FIFO buffer. • Gateway mode: Setting prohibited	W
b31 to b8	—	Reserved	The write value should be 0.	W

CFPC[7:0] Bits (Transmit/Receive FIFO Pointer Control)

- Reception mode (CFM[1:0] value in the RSCAN0CFCCk register is 00b):
  Writing FFh to the CFPC[7:0] bits moves the read pointer to the next unread message in the transmission/reception FIFO buffer. At this time, the CFMC[7:0] value (transmit/receive FIFO message counter) in the RSCAN0CFSTSk register is decremented. Read the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers to read messages from the transmission/reception FIFO buffer, and then write FFh to the CFPC[7:0] bits.
  When writing FFh to these bits, make sure that the CFE bit in the RSCAN0CFCCk register is set to 1 (transmission/reception FIFO buffers are used) and the CFEMP flag in the RSCAN0CFSTSk register is 0 (the transmission/reception FIFO buffer contains messages).
- Transmission mode (CFM[1:0] value in the RSCAN0CFCCk register is 01b):
  Writing FFh to the CFPC[7:0] bits stores the data written to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers in the transmission/reception FIFO buffer and moves the write pointer to the next stage of the transmission/reception FIFO buffer. At this time, the CFMC[7:0] value is incremented. Write messages for transmission to the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers before writing FFh to the CFPC[7:0] bits.
  When writing FFh to these bits, make sure that the CFE bit in the RSCAN0CFCCk register is set to 1 and the CFFLL flag in the RSCAN0CFSTSk register is 0 (the transmission/reception FIFO buffer is not full).
- Gateway mode (CFM[1:0] value in the RSCAN0CFCCk register is 10b):
  Setting prohibited

35.2.33 Transmission/Reception FIFO Buffer Access ID Registers (RSCAN0CFIDk) (k = 0 to 5)

The RSCAN0CFIDk registers are status registers that indicate the state of the ID and data formats of the received messages stored in the transmission/reception FIFO buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1).
These registers are writable only when the CFM[1:0] value in the RSCAN0CFCCk register is 01b (transmission mode) and readable only when the CFM[1:0] value is 00b (reception mode). These registers should not be read or written when the CFM[1:0] value is 10b (gateway mode).

Address(es): RSCAN.RSCAN0CFID0 A007 8E80h, RSCAN.RSCAN0CFID1 A007 8E90h, RSCAN.RSCAN0CFID2 A007 8EA0h, RSCAN.RSCAN0CFID3 A007 8EB0h, RSCAN.RSCAN0CFID4 A007 8EC0h, RSCAN.RSCAN0CFID5 A007 8ED0h

Bit	Symbol	Bit Name	Description	R/W
b28 to b0	CFID[28:0]	Transmission/Reception FIFO Buffer ID Data Set	• When CFM[1:0] value is 01b (transmission mode): Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11. • When CFM[1:0] value is 00b (reception mode): Standard ID or extended ID in the received message can be read. For standard ID, read bits 10 to 0. Bits 28 to 11 are read as 0.	R/W
b29	THLEN	Transmission History Data Storage Enable	This bit is valid only when the CFM[1:0] value is 01b (transmission mode). 0: Transmission history data is not stored in the buffer. 1: Transmission history data is stored in the buffer.	R/W
b30	CFRTR	Transmission/Reception FIFO Buffer RTR	0: Data frame 1: Remote frame	R/W
b31	CFIDE	Transmission/Reception FIFO Buffer IDE	0: Standard ID 1: Extended ID	R/W

CFID[28:0] Bits (Transmission/Reception FIFO Buffer ID Data Set)

These bits contain the ID of the received message stored in the transmission/reception FIFO buffer when the CFM[1:0] value is 00b.
When the CFM[1:0] value is 01b, this bit is used to set the ID of the message to be transmitted from the transmission/reception FIFO buffer.

THLEN Bit (Transmission History Data Storage Enable)

When this bit is set to 1, the transmission history data (label information, buffer number, and buffer type) of transmitted messages is stored in the transmission history buffer after transmission is completed.
This bit is enabled when the CFM[1:0] value is 01b (transmission mode).

CFRTR Bit (Transmission/Reception FIFO Buffer RTR)

This bit indicates the data format (data frame or remote frame) of the received message stored in the transmission/reception FIFO buffer when the CFM[1:0] value is 00b. When the CFM[1:0] value is 01b, this bit is used to set the data format of the message to be transmitted from the transmission/reception FIFO buffer.

CFIDE Bit (Transmission/Reception FIFO Buffer IDE)

This bit indicates the ID format (standard ID or extended ID) of the received message stored in the transmission/reception FIFO buffer when the CFM[1:0] value is 00b. When the CFM[1:0] value is 01b, these bits are used to set the ID format of the message to be transmitted from the transmission/reception FIFO buffer.

35.2.34 Transmission/Reception FIFO Buffer Access Pointer Registers (RSCAN0CFPTRk) (k = 0 to 5)

The RSCAN0CFPTRk registers are status registers that indicate the data length, label information, and timestamp value of the received messages stored in the transmission/reception buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1). These registers are writable only when the CFM[1:0] value in the RSCAN0CFCCk register is 01b (transmission mode) and readable only when the CFM[1:0] value is 00b (reception mode). These registers should not be read or written when the CFM[1:0] value is 10b (gateway mode).

Address(es): RSCAN.RSCAN0CFPTR0 A007 8E84h, RSCAN.RSCAN0CFPTR1 A007 8E94h, RSCAN.RSCAN0CFPTR2 A007 8EA4h, RSCAN.RSCAN0CFPTR3 A007 8EB4h, RSCAN.RSCAN0CFPTR4 A007 8EC4h, RSCAN.RSCAN0CFPTR5 A007 8ED4h

CFTS[15:0] Bits

These bits indicate the timestamp value of the message stored in the transmission/reception FIFO buffer.
These bits are valid when the CFM[1:0] value is 00b.

CFPTR[11:0] Bits

These bits indicate the label information attached to the received message stored in the transmission/reception FIFO buffer when the CFM[1:0] value is 00b. When the CFM[1:0] value is 01b, the CFPTR[7:0] value is stored in the transmission history buffer when message transmission has been completed.

CFDLC[3:0] Bits

These bits indicate the data length of the received message stored in the transmission/reception FIFO buffer when the CFM[1:0] value is 00b. When the CFM[1:0] value is 01b, these bits are used to set the data length of the message to be transmitted from the transmission/reception FIFO buffer. If the data length is set to 9 bytes or more, the actual transmit data defaults to 8 bytes.

35.2.35 Transmission/Reception FIFO Buffer Access Data Field 0 Registers (RSCAN0CFDF0k) (k = 0 to 5)

The RSCAN0CFDF0k registers are data registers that hold the values in the transmission/reception FIFO buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1).

These registers are writable only when the CFM[1:0] value in the RSCAN0CFCCk register is 01b (transmission mode) and readable only when the CFM[1:0] value is 00b (reception mode). When the CFDLC[3:0] value in the RSCAN0CFPTRk register is smaller than 1000b, data bytes for which no data is set are read as 00h.

These registers should not be read or written when the CFM[1:0] value is 10b (gateway mode).

Address(es): RSCAN.RSCAN0CFDF00 A007 8E88h, RSCAN.RSCAN0CFDF01 A007 8E98h, RSCAN.RSCAN0CFDF02 A007 8EA8h, RSCAN.RSCAN0CFDF03 A007 8EB8h, RSCAN.RSCAN0CFDF04 A007 8EC8h, RSCAN.RSCAN0CFDF05 A007 8ED8h

35.2.36 Transmission/Reception FIFO Buffer Access Data Field 1 Registers (RSCAN0CFDF1k) (k = 0 to 5)

The RSCAN0CFDF1k registers are data registers that hold the values in the transmission/reception buffers (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1).

These registers are writable only when the CFM[1:0] value in the RSCAN0CFCCk register is 01b (transmission mode) and readable only when the CFM[1:0] value is 00b (reception mode). When the CFDLC[3:0] value in the RSCAN0CFPTRk register is smaller than 1000b, data bytes for which no data is set are read as 00h.

These registers should not be read or written when the CFM[1:0] value is 10b (gateway mode).

35.2.37 FIFO Empty Status Register (RSCAN0FESTS)

The RSCAN0FESTS register is a status register that indicates whether receive FIFOx (x = 0 to 7) and transmit/receive FIFOk (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1) are empty.
The RSCAN0FESTS register is set to 03FF FFFFh in global reset mode.

Address(es): RSCAN.RSCAN0FESTS A007 8238h

b16 to b14	—	Reserved	These bits are read as 1.	R
b31 to b17	—	Reserved	These bits are read as 0.	R

RFxEMP Flag (x = 0 to 7)

The RFxEMP flag is set to 1 when the RFEMP flag in the RSCAN0RFSTSx register is set to 1 (the reception FIFO buffer contains no unread message). When the RFEMP flag is cleared to 0 (the reception FIFO buffer contains unread messages), the RFxEMP flag is cleared to 0.

CFkEMP Flag (k = 0 to 5)

The CFkEMP flag is set to 1 when the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the transmission/reception FIFO buffer contains no message (buffer empty)). When the CFEMP flag is cleared to 0 (the transmission/reception FIFO buffer contains messages), the CFkEMP flag is cleared to 0.

35.2.38 FIFO Full Status Register (RSCAN0FFSTS)

The RSCAN0FFSTS register is a status register that indicates whether receive FIFOx (x = 0 to 7) and transmit/receive FIFOk (k = 0 to 2 for channel 0; k = 3 to 5 for channel 1) are full.
The RSCAN0FFSTS register is cleared to 0000 0000h in global reset mode.

Address(es): RSCAN.RSCAN0FFSTS A007 823Ch

b12	CF4FLL			R
b13	CF5FLL			R
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/(W)

RFxFLL Flag (x = 0 to 7)

The RFxFLL flag is set to 1 when the RFFLL flag in the RSCAN0RFSTSx register is set to 1 (the reception FIFO buffer is full). When the RFFLL flag is cleared to 0 (the reception FIFO buffer is not full), the RFxFLL flag is cleared to 0.

CFkFLL Flag (k = 0 to 5)

The CFkFLL flag is set to 1 when the CFFLL flag in the RSCAN0CFSTSk register is set to 1 (the transmission/reception FIFO buffer is full). When the CFFLL flag is cleared to 0 (the transmission/reception FIFO buffer is not full), the CFkFLL flag is cleared to 0.

35.2.39 FIFO Message Lost Status Register (RSCAN0FMSTS)

The RSCAN0FMSTS register is a status register that indicates whether messages in receive FIFOx (x = 0 to 7) and transmit/receive FIFOk (k 0 to 2 for channel 0; k = 3 to 5 for channel 1) have been lost.
The RSCAN0FMSTS register is cleared to 0000 0000h in global reset mode.

Address(es): RSCAN.RSCAN0FMSTS A007 8240h

b12	CF4MLT			R
b13	CF5MLT			R
b31 to b14	—	Reserved	These bits are read as 0.	R

RFxMLT Flag (x = 0 to 7)

The RFxMLT flag is set to 1 when the RFMLT flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO message is lost). When the RFMLT flag is cleared to 0, the RFxMLT flag is cleared to 0.

CFkMLT Flag (k = 0 to 5)

The CFkMLT flag is set to 1 when the CFMLT flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO message is lost). When the CFMLT flag is cleared to 0, the CFkMLT flag is cleared to 0.

35.2.40 Reception FIFO Buffer Interrupt Flag Status Register (RSCAN0RFISTS)

The RSCAN0RFISTS register is a flag register that indicates interrupts from the reception FIFO buffer.
The RSCAN0RFISTS register is cleared to 0000 0000h in global reset mode.

Address(es): RSCAN.RSCAN0RFISTS A007 8244h

b6	RF6IF			R
b7	RF7IF			R
b31 to b8	—	Reserved	These bits are read as 0.	R

RFxIF Flag (x = 0 to 7)

The RFxIF flag is set to 1 when the RFIF flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO interrupt request is present). When the RFIF flag is cleared to 0, the RFxIF flag is cleared to 0.

35.2.41 Transmission/Reception FIFO Buffer Receive Interrupt Flag Status Register (RSCAN0CFRISTS)

The RSCAN0CFRISTS register is a flag register that indicates reception interrupts from the transmission/reception FIFO buffer.

The RSCAN0CFRISTS register is cleared to 0000 0000h in global reset mode.

Address(es): RSCAN.RSCAN0CFRISTS A007 8248h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b31 to b6	—	Reserved	These bits are read as 0.	R

CFkRXIF Flag (k = 0 to 5)

The CFkRXIF flag is set to 1 when the CFRXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). When the CFRXIF flag is cleared to 0, the CFkRXIF flag is cleared to 0.

35.2.42 Transmission/Reception FIFO Buffer Transmit Interrupt Flag Status Register (RSCAN0CFTISTS)

The RSCAN0CFTISTS register is a flag register that indicates transmission interrupts from the transmission/reception FIFO buffer.

The RSCAN0CFTISTS register is cleared to 0000 0000h in global reset mode.

Address(es): RSCAN.RSCAN0CFTISTS A007 824Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b3	CF3TXIF			R
b4	CF4TXIF			R
b5	CF5TXIF			R
b31 to b6	—	Reserved	These bits are read as 0.	R

CFkTXIF Flag (k = 0 to 5)

The CFkTXIF flag is set to 1 when the CFTXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO transmit interrupt request is present). When the CFTXIF flag is cleared to 0, the CFkTXIF flag is cleared to 0.

35.2.43 Transmission Buffer Control Register (RSCAN0TMCp) (p = 0 to 31)

The RSCAN0TMCp registers control the settings for the transmission buffers (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

Set the RSCAN0TMCp registers to 00h when any of the following conditions is met.

- The RSCAN0TMCp register corresponds to the transmission buffer number selected by the CFTML[3:0] bits in the RSCAN0CFCCk register (p = m × 16 + the value of CFTML[3:0] bits) (m = 0, k = 0 to 2 for channel 0; m = 1, k = 3 to 5 for channel 1).
- The RSCAN0TMCp register corresponds to the transmission buffer allocated to the transmission queue by the TXQDC[3:0] bits in the RSCAN0TXQCCm register (p = (m × 16 + 15) to (m × 16 + 15 – the value of TXQDC[3:0] bits)).

Bits in the RSCAN0TMCp registers are all cleared to 0 in channel reset mode.

Modify the RSCAN0TMCp registers in channel communication mode or channel halt mode.

Address(es): RSCAN.RSCAN0TMC0 A007 8250h, RSCAN.RSCAN0TMC1 A007 8251h, RSCAN.RSCAN0TMC2 A007 8252h, RSCAN.RSCAN0TMC3 A007 8253h, RSCAN.RSCAN0TMC4 A007 8254h, RSCAN.RSCAN0TMC5 A007 8255h, RSCAN.RSCAN0TMC6 A007 8256h, RSCAN.RSCAN0TMC7 A007 8257h, RSCAN.RSCAN0TMC8 A007 8258h, RSCAN.RSCAN0TMC9 A007 8259h, RSCAN.RSCAN0TMC10 A007 825Ah, RSCAN.RSCAN0TMC11 A007 825Bh, RSCAN.RSCAN0TMC12 A007 825Ch, RSCAN.RSCAN0TMC13 A007 825Dh, RSCAN.RSCAN0TMC14 A007 825Eh, RSCAN.RSCAN0TMC15 A007 825Fh, RSCAN.RSCAN0TMC16 A007 8260h, RSCAN.RSCAN0TMC17 A007 8261h, RSCAN.RSCAN0TMC18 A007 8262h, RSCAN.RSCAN0TMC19 A007 8263h, RSCAN.RSCAN0TMC20 A007 8264h, RSCAN.RSCAN0TMC21 A007 8265h, RSCAN.RSCAN0TMC22 A007 8266h, RSCAN.RSCAN0TMC23 A007 8267h, RSCAN.RSCAN0TMC24 A007 8268h, RSCAN.RSCAN0TMC25 A007 8269h, RSCAN.RSCAN0TMC26 A007 826Ah, RSCAN.RSCAN0TMC27 A007 826Bh, RSCAN.RSCAN0TMC28 A007 826Ch, RSCAN.RSCAN0TMC29 A007 826Dh, RSCAN.RSCAN0TMC30 A007 826Eh, RSCAN.RSCAN0TMC31 A007 826Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	TMOM	TMTAR	TMTR
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TMTR	Transmission Request	0: Transmission is not requested. 1: Transmission is requested.	R/W *1
b1	TMTAR	Transmission Abort Request	0: Transmission abort is not requested. 1: Transmission abort is requested.	R/W *1
b2	TMOM	One-Shot Transmission Enable	0: One-shot transmission is disabled. 1: One-shot transmission is enabled.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. The only effective value for writing to this bit is 1, which sets the bit. Otherwise writing to the bit results in retention of its state.

TMTR Bit (Transmission Request)

Setting this bit to 1 transmits the message stored in the transmission buffer.

The TMTR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmission abort has been completed after the TMTAR bit was set to 1.
- An error or arbitration-lost has been detected with the TMOM bit set to 1.

Set the TMTR bit to 1 when the value of TMTRF[1:0] in the RSCAN0TMSTSp register is 00b.

TMTAR Bit (Transmission Abort Request)

Setting this bit to 1 generates a transmission abort request for the message stored in the transmission buffer. However, a message that is being transmitted or one that will be transmitted next cannot be aborted.
The TMTAR bit can be set to 1 when TMTR bit is 1.
The TMTAR bit is cleared to 0 when any of the following conditions is met, but cannot be cleared by the program writing 0 to the bit.

- Transmission has been completed.
- Transmission abort has been completed.
- An error or arbitration loss has been detected.

If this bit becomes 0 at the same time as the program writes 1 to this bit, this bit becomes 0.

TMOM Bit (One-Shot Transmission Enable)

Setting this bit to 1 enables one-shot transmission. When transmission fails, retransmission defined in the CAN protocol is not performed.
Modify the TMOM bit when the TMTRM flag in the RSCAN0TMSTSp register is set to 0. Set the TMOM bit to 1 together with the TMTR bit.

35.2.44 Transmission Buffer Status Registers (RSCAN0TMSTSp) (p = 0 to 31)

The RSCAN0TMSTSp registers are status registers that indicate the state of the transmission buffers (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

Bits in the RSCAN0TMSTSp registers are all cleared to 0 in channel reset mode.

Address(es): RSCAN.RSCAN0TMSTS0 A007 82D0h, RSCAN.RSCAN0TMSTS1 A007 82D1h, RSCAN.RSCAN0TMSTS2 A007 82D2h, RSCAN.RSCAN0TMSTS3 A007 82D3h, RSCAN.RSCAN0TMSTS4 A007 82D4h, RSCAN.RSCAN0TMSTS5 A007 82D5h, RSCAN.RSCAN0TMSTS6 A007 82D6h, RSCAN.RSCAN0TMSTS7 A007 82D7h, RSCAN.RSCAN0TMSTS8 A007 82D8h, RSCAN.RSCAN0TMSTS9 A007 82D9h, RSCAN.RSCAN0TMSTS10 A007 82DAh, RSCAN.RSCAN0TMSTS11 A007 82DBh, RSCAN.RSCAN0TMSTS12 A007 82DCh, RSCAN.RSCAN0TMSTS13 A007 82DDh, RSCAN.RSCAN0TMSTS14 A007 82DEh, RSCAN.RSCAN0TMSTS15 A007 82DFh, RSCAN.RSCAN0TMSTS16 A007 82E0h, RSCAN.RSCAN0TMSTS17 A007 82E1h, RSCAN.RSCAN0TMSTS18 A007 82E2h, RSCAN.RSCAN0TMSTS19 A007 82E3h, RSCAN.RSCAN0TMSTS20 A007 82E4h, RSCAN.RSCAN0TMSTS21 A007 82E5h, RSCAN.RSCAN0TMSTS22 A007 82E6h, RSCAN.RSCAN0TMSTS23 A007 82E7h, RSCAN.RSCAN0TMSTS24 A007 82E8h, RSCAN.RSCAN0TMSTS25 A007 82E9h, RSCAN.RSCAN0TMSTS26 A007 82EAh, RSCAN.RSCAN0TMSTS27 A007 82EBh, RSCAN.RSCAN0TMSTS28 A007 82ECh, RSCAN.RSCAN0TMSTS29 A007 82EDh, RSCAN.RSCAN0TMSTS30 A007 82EEh, RSCAN.RSCAN0TMSTS31 A007 82EFh

b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TMTSTS Flag (Transmission Buffer Transmission Status Flag)

This flag is set to 1 when transmission from the transmission buffer starts, and is cleared to 0 when transmission from the transmission buffer has been completed or terminated due to a bus error or arbitration lost.

TMTRF[1:0] Flag (Transmission Buffer Transmission Result Status Flag)

This flag indicates the result of transmission from the transmission buffer.

00b: Transmission is in progress or no transmission request is present.

01b: Transmission from the transmission buffer was aborted.

10b: Transmission has been completed with the TMTAR bit in the RSCAN0TMCp register set to 0 (transmission abort is not requested).

11b: Transmission has been completed with the TMTAR bit in the RSCAN0TMCp register set to 1 (transmission abort is requested).

Write 00b to the TMTRF[1:0] flag in channel communication mode or channel halt mode. Do not write any value other than 00b to this flag.

TMTRM Flag (Transmission Buffer Transmission Request Status Flag)

The TMTRM flag is set to 1 when the TMTR bit in the RSCAN0TMCp register is set to 1.
The TMTRM flag is set to 0 when the TMTR bit in the RSCAN0TMCp register is set to 0.

TMTARM Flag (Transmission Buffer Transmission Abort Request Status Flag)

The TMTARM flag is set to 1 when the TMTAR bit in the RSCAN0TMCp register is set to 1.
The TMTARM flag is set to 0 when the TMTAR bit in the RSCAN0TMCp register is set to 0.

35.2.45 Transmission Buffer Transmission Request Status Register 0 (RSCAN0TMTRSTS0)

The RSCAN0TMTRSTS0 register is a status register that indicates requests for the transmission by the transmission buffer.

Address(es): RSCAN.RSCAN0TMTRSTS0 A007 8350h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMTRSTSp (p = 31 to 16)

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TMTRSTSp	Transmission Buffer Transmission Request Status Flag p (p = 15 to 0)	0: No transmission request is present. 1: A transmission request is present.	R
b31 to b16	TMTRSTSp	Transmission Buffer Transmission Request Status Flag p (p = 31 to 16)	0: No transmission request is present. 1: A transmission request is present.	R

TMTRSTSp Flags (p = 0 to 31) (Transmission Buffer Transmission Request Status Flags p)

These flags indicate the status of the TMTR bit in the RSCAN0TMCp register (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

When the TMTR bit is set to 1 (transmission is requested), the corresponding TMTRSTSp flag is set to 1.

The corresponding TMTRSTSp flag is cleared to 0 when the TMTR bit is set to 0 (transmission is not requested) or in channel reset mode.

Table 35.5 shows the bit assignment.

Table 35.5 TMTRSTSp Bit Assignment

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TMTARSTSp	Transmission Buffer Transmission Abort Request Status Flag p (p = 15 to 0)	0: No transmission abort request is present. 1: A transmission abort request is present.	R
b31 to b16	TMTARSTSp	Transmission Buffer Transmission Abort Request Status Flag p (p = 31 to 16)	0: No transmission abort request is present. 1: A transmission abort request is present.	R

TMTARSTSp Flags (Transmission Buffer Transmission Abort Request Status Flags p) (p = 0 to 31)

These flags indicate the status of the TMTAR bit in the RSCAN0TMCp register (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

When the TMTAR bit is set to 1 (transmission abort is requested), the corresponding TMTARSTSp flag is set to 1.

The corresponding TMTARSTSp flag is cleared to 0 when the TMTAR bit is set to 0 (transmission abort is not requested) or in channel reset mode.

Table 35.6 shows the bit assignment.

Table 35.6 TMTARSTSp Bit Assignment

35.2.47 Transmission Buffer Transmission Complete Status Register 0 (RSCAN0TMTCSTS0)

The RSCAN0TMTCSTS0 register is a status register that indicates requests for the completion of transmission by the transmission buffer.

Address(es): RSCAN.RSCAN0TMTCSTS0 A007 8370h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMTCSTSp (p = 31 to 16)

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TMTCSTSp	Transmission Buffer Transmission Complete Status Flag p (p = 15 to 0)	0: Transmission has not been completed. 1: Transmission has been completed.	R
b31 to b16	TMTCSTSp	Transmission Buffer Transmission Complete Status Flag p (p = 31 to 16)	0: Transmission has not been completed. 1: Transmission has been completed.	R

TMTCSTSp Flags (Transmission Buffer Transmission Complete Status Flags p) (p = 0 to 31)

When the TMTRF[1:0] flag in the RSCAN0TMSTSp register is set to 10b (transmission has been completed (without transmission abort request)) or 11b (transmission has been completed (with transmission abort request)), the corresponding TMTCSTSp flag is set to 1 (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).
A TMTCSTSp flag is cleared to 0 when the corresponding TMTRF[1:0] flag is set to 00b or in channel reset mode.
Table 35.7 shows the bit assignment.

Table 35.7 TMTCSTSp Bit Assignment

	TMTASTSp (p = 15 to 0)															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TMTASTSp	Transmission Buffer Transmission Abort Status Flag p (p = 15 to 0)	0: Transmission is not aborted. 1: Transmission is aborted.	R
b31 to b16	TMTASTSp	Transmission Buffer Transmission Abort Status Flag p (p = 31 to 16)	0: Transmission is not aborted 1: Transmission is aborted	R

TMTASTSp Flags (Transmission Buffer Transmission Abort Status Flags p) (p = 0 to 31)

When the TMTRF[1:0] flag in the RSCAN0TMSTSp register is set to 01b (transmission abort has been completed), the corresponding TMTASTSp flag is set to 1 (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

A TMTASTSp flag is cleared to 0 when the corresponding TMTRF[1:0] flag is set to 00b or in channel reset mode.

Table 35.8 shows the bit assignment.

Table 35.8 TMTASTSp Bit Assignment

Bit	Channel	Transmission Buffer Number
0	0	0
1	0	1
. .	. .	. .
15	0	15
16	1	16
. .	. .	. .

31	1	31

35.2.49 Transmission Buffer Interrupt Enable Configuration Register 0 (RSCAN0TMIEC0)

The RSCAN0TMIEC0 register enables or disables requests for transmission buffer interrupts.

Address(es): RSCAN.RSCAN0TMIEC0 A007 8390h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	TMIEp (p = 31 to 16)															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TMIEp (p = 15 to 0)															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	TMIEp	Transmission Buffer Interrupt Enable p (p = 15 to 0)	0: Transmission buffer interrupt is disabled. 1: Transmission buffer interrupt is enabled.	R/W
b31 to b16	TMIEp	Transmission Buffer Interrupt Enable p (p = 31 to 16)	0: Transmission buffer interrupt is disabled 1: Transmission buffer interrupt is enabled	R/W

TMIEp Bits (Transmission Buffer Interrupt Enable p) (p = 0 to 31)

When any of these bits is set to 1 and the corresponding transmission has been completed, a CANm transmission interrupt request (transmission buffer interrupt) is generated (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).
Modify these bits when the TMTRM flag in the corresponding RSCAN0TMSTSp register is 0 (no transmission request is present).
Write 0 to bits corresponding to transmission buffers linked to transmission/reception FIFO buffers or transmission buffers allocated to the transmission queue.
Table 35.9 shows the bit assignment.

Table 35.9 TMIEp Bit Assignment

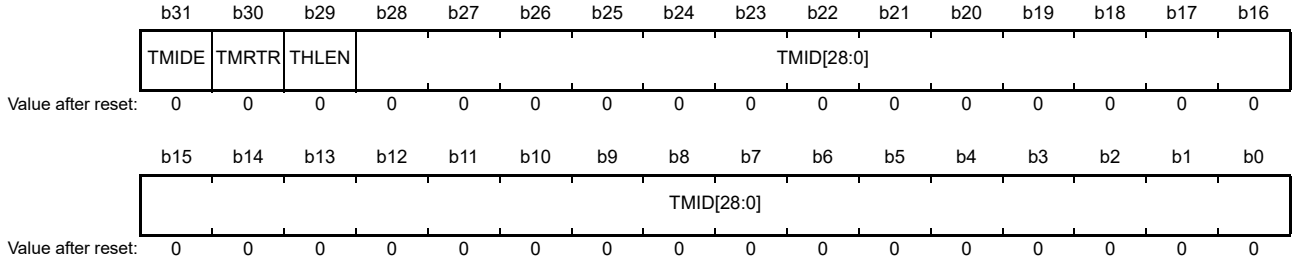
Bit	Channel	Transmission Buffer Number
0	0	0
1	0	1
. .	. .	. .
15	0	15
16	1	16
. .	. .	. .
30	1	30
31	1	31

35.2.50 Transmission Buffer ID Registers (RSCAN0TMIDp) (p = 0 to 31)

The RSCAN0TMIDp registers control the ID and data formats of the messages for transmission (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

Modify these registers when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmission request is present). If these registers are linked to transmission/reception FIFO buffers, do not write data to them. If these registers are allocated to the transmission queue, write data only to transmission buffers p (p = m × 16 + 15) for the corresponding channel m (m = 0, 1).

Address(es): RSCAN.RSCAN0TMID0 A007 9000h, RSCAN.RSCAN0TMID1 A007 9010h, RSCAN.RSCAN0TMID2 A007 9020h, RSCAN.RSCAN0TMID3 A007 9030h, RSCAN.RSCAN0TMID4 A007 9040h, RSCAN.RSCAN0TMID5 A007 9050h, RSCAN.RSCAN0TMID6 A007 9060h, RSCAN.RSCAN0TMID7 A007 9070h, RSCAN.RSCAN0TMID8 A007 9080h, RSCAN.RSCAN0TMID9 A007 9090h, RSCAN.RSCAN0TMID10 A007 90A0h, RSCAN.RSCAN0TMID11 A007 90B0h, RSCAN.RSCAN0TMID12 A007 90C0h, RSCAN.RSCAN0TMID13 A007 90D0h, RSCAN.RSCAN0TMID14 A007 90E0h, RSCAN.RSCAN0TMID15 A007 90F0h, RSCAN.RSCAN0TMID16 A007 9100h, RSCAN.RSCAN0TMID17 A007 9110h, RSCAN.RSCAN0TMID18 A007 9120h, RSCAN.RSCAN0TMID19 A007 9130h, RSCAN.RSCAN0TMID20 A007 9140h, RSCAN.RSCAN0TMID21 A007 9150h, RSCAN.RSCAN0TMID22 A007 9160h, RSCAN.RSCAN0TMID23 A007 9170h, RSCAN.RSCAN0TMID24 A007 9180h, RSCAN.RSCAN0TMID25 A007 9190h, RSCAN.RSCAN0TMID26 A007 91A0h, RSCAN.RSCAN0TMID27 A007 91B0h, RSCAN.RSCAN0TMID28 A007 91C0h, RSCAN.RSCAN0TMID29 A007 91D0h, RSCAN.RSCAN0TMID30 A007 91E0h, RSCAN.RSCAN0TMID31 A007 91F0h



Bit	Symbol	Bit Name	Description	R/W
b28 to b0	TMID[28:0]	Transmission Buffer ID Data Configuration	Set standard ID or extended ID. For standard ID, write an ID to bits 10 to 0 and write 0 to bits 28 to 11.	R/W
b29	THLEN	Transmission History Data Storage Enable	0: Transmission history data is not stored in the buffer. 1: Transmission history data is stored in the buffer.	R/W
b30	TMRTR	Transmission Buffer RTR	0: Data frame 1: Remote frame	R/W
b31	TMIDE	Transmission Buffer IDE	0: Standard ID 1: Extended ID	R/W

TMID[28:0] Bits (Transmission Buffer ID Data Configuration)

These bits are used to set the ID of the message to be transmitted from the transmission buffer.

THLEN Bit (Transmission History Data Storage Enable)

With this bit set to 1, the transmission history data of the message transmitted (label information and the number and type) are stored in the transmission history buffer after transmission is completed.

TMRTR Bit (Transmission Buffer RTR)

This bit is used to set the data format of the message to be transmitted from the transmission buffer.

TMIDE Bit (Transmission Buffer IDE)

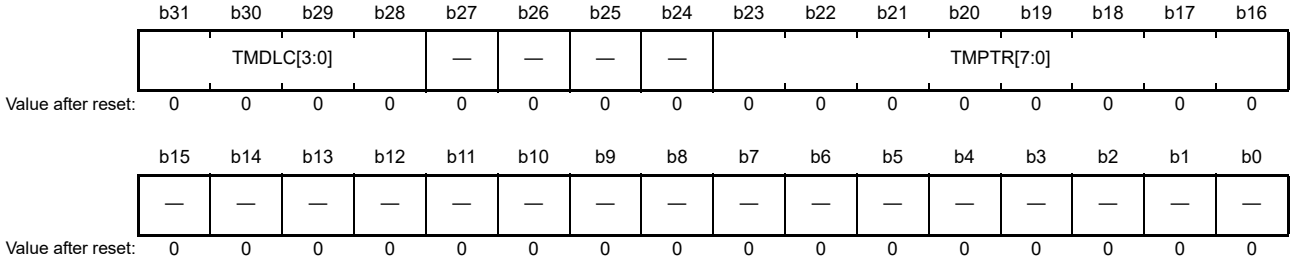
This bit is used to set the ID format of the message to be transmitted from the transmission buffer.

35.2.51 Transmission Buffer Pointer Registers (RSCAN0TMPTRp) (p = 0 to 31)

The RSCAN0TMPTRp registers control the data length and label information for the messages for transmission (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

Modify these registers when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmission request is present). If these registers are linked to transmission/reception FIFO buffers, do not write data to them. If these registers are allocated to the transmission queue, write data only to transmission buffers p (p = m × 16 + 15) for the corresponding channel m (m = 0, 1).

Address(es): RSCAN.RSCAN0TMPTR0 A007 9004h, RSCAN.RSCAN0TMPTR1 A007 9014h, RSCAN.RSCAN0TMPTR2 A007 9024h, RSCAN.RSCAN0TMPTR3 A007 9034h, RSCAN.RSCAN0TMPTR4 A007 9044h, RSCAN.RSCAN0TMPTR5 A007 9054h, RSCAN.RSCAN0TMPTR6 A007 9064h, RSCAN.RSCAN0TMPTR7 A007 9074h, RSCAN.RSCAN0TMPTR8 A007 9084h, RSCAN.RSCAN0TMPTR9 A007 9094h, RSCAN.RSCAN0TMPTR10 A007 90A4h, RSCAN.RSCAN0TMPTR11 A007 90B4h, RSCAN.RSCAN0TMPTR12 A007 90C4h, RSCAN.RSCAN0TMPTR13 A007 90D4h, RSCAN.RSCAN0TMPTR14 A007 90E4h, RSCAN.RSCAN0TMPTR15 A007 90F4h, RSCAN.RSCAN0TMPTR16 A007 9104h, RSCAN.RSCAN0TMPTR17 A007 9114h, RSCAN.RSCAN0TMPTR18 A007 9124h, RSCAN.RSCAN0TMPTR19 A007 9134h, RSCAN.RSCAN0TMPTR20 A007 9144h, RSCAN.RSCAN0TMPTR21 A007 9154h, RSCAN.RSCAN0TMPTR22 A007 9164h, RSCAN.RSCAN0TMPTR23 A007 9174h, RSCAN.RSCAN0TMPTR24 A007 9184h, RSCAN.RSCAN0TMPTR25 A007 9194h, RSCAN.RSCAN0TMPTR26 A007 91A4h, RSCAN.RSCAN0TMPTR27 A007 91B4h, RSCAN.RSCAN0TMPTR28 A007 91C4h, RSCAN.RSCAN0TMPTR29 A007 91D4h, RSCAN.RSCAN0TMPTR30 A007 91E4h, RSCAN.RSCAN0TMPTR31 A007 91F4h



Bit	Symbol	Bit Name	Description	R/W
b15 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b23 to b16	TMPTR[7:0]	Transmission Buffer Label Data Configuration	Set the label information to be stored in the transmission history buffer.	R/W
b27 to b24	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31 to b28	TMDLC[3:0]	Transmission Buffer DLC Data Configuration	b31 b30 b29 b28 0 0 0 0: 0 data bytes 0 0 0 1: 1 data byte 0 0 1 0: 2 data bytes 0 0 1 1: 3 data bytes 0 1 0 0: 4 data bytes 0 1 0 1: 5 data bytes 0 1 1 0: 6 data bytes 0 1 1 1: 7 data bytes 1 X X X: 8 data bytes	R/W

TMPTR[7:0] Bits (Transmission Buffer Label Data Configuration)

When message transmission has been completed, the TMPTR[7:0] value is stored in the transmission history buffer.

TMDLC[3:0] Bits (Transmission Buffer DLC Data Configuration)

These bits are used to set the data length of the message to be transmitted from the transmission buffer when the TMRTR bit in the RSCAN0TMIDp register is set to 0 (data frame). If the data length is set to 9 bytes or more, the transmit data is 8 bytes long.

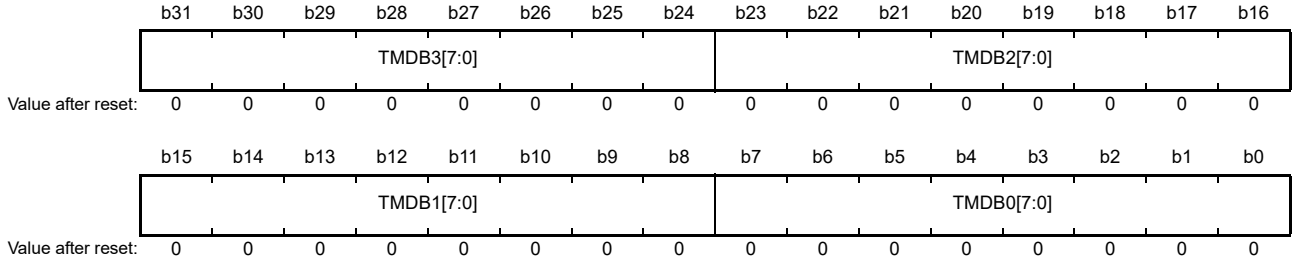
When the TMRTR bit is set to 1 (remote frame), set the data length of messages to be requested.

35.2.52 Transmission Buffer Data Field 0 Registers (RSCAN0TMDF0p) (p = 0 to 31)

The RSCAN0TMDF0p registers are data registers for writing data for transmission from the transmission buffer (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

Modify these registers when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmission request is present). If these registers are linked to transmission/reception FIFO buffers, do not write data to them. If these registers are allocated to the transmission queue, write data only to transmission buffers p (p = m × 16 + 15) for the corresponding channel m (m = 0, 1).

Address(es): RSCAN.RSCAN0TMDF00 A007 9008h, RSCAN.RSCAN0TMDF01 A007 9018h, RSCAN.RSCAN0TMDF02 A007 9028h, RSCAN.RSCAN0TMDF03 A007 9038h, RSCAN.RSCAN0TMDF04 A007 9048h, RSCAN.RSCAN0TMDF05 A007 9058h, RSCAN.RSCAN0TMDF06 A007 9068h, RSCAN.RSCAN0TMDF07 A007 9078h, RSCAN.RSCAN0TMDF08 A007 9088h, RSCAN.RSCAN0TMDF09 A007 9098h, RSCAN.RSCAN0TMDF010 A007 90A8h, RSCAN.RSCAN0TMDF011 A007 90B8h, RSCAN.RSCAN0TMDF012 A007 90C8h, RSCAN.RSCAN0TMDF013 A007 90D8h, RSCAN.RSCAN0TMDF014 A007 90E8h, RSCAN.RSCAN0TMDF015 A007 90F8h, RSCAN.RSCAN0TMDF016 A007 9108h, RSCAN.RSCAN0TMDF017 A007 9118h, RSCAN.RSCAN0TMDF018 A007 9128h, RSCAN.RSCAN0TMDF019 A007 9138h, RSCAN.RSCAN0TMDF020 A007 9148h, RSCAN.RSCAN0TMDF021 A007 9158h, RSCAN.RSCAN0TMDF022 A007 9168h, RSCAN.RSCAN0TMDF023 A007 9178h, RSCAN.RSCAN0TMDF024 A007 9188h, RSCAN.RSCAN0TMDF025 A007 9198h, RSCAN.RSCAN0TMDF026 A007 91A8h, RSCAN.RSCAN0TMDF027 A007 91B8h, RSCAN.RSCAN0TMDF028 A007 91C8h, RSCAN.RSCAN0TMDF029 A007 91D8h, RSCAN.RSCAN0TMDF030 A007 91E8h, RSCAN.RSCAN0TMDF031 A007 91F8h



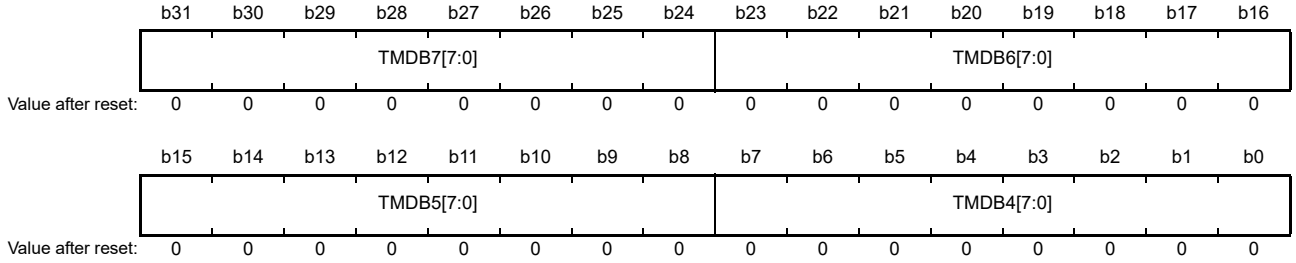
Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TMDB0[7:0]	Transmission Buffer Data Byte 0	Set the transmission buffer data.	R/W
b15 to b8	TMDB1[7:0]	Transmission Buffer Data Byte 1		R/W
b23 to b16	TMDB2[7:0]	Transmission Buffer Data Byte 2		R/W
b31 to b24	TMDB3[7:0]	Transmission Buffer Data Byte 3		R/W

35.2.53 Transmission Buffer Data Field 1 Registers (RSCAN0TMDF1p) (p = 0 to 31)

The RSCAN0TMDF1p registers are data registers for writing data for transmission from the transmission buffer (p = 0 to 15 for channel 0; p = 16 to 31 for channel 1).

Modify these registers when the TMTRM bit in the corresponding RSCAN0TMSTSp register is set to 0 (no transmission request is present). If these registers are linked to transmission/reception FIFO buffers, do not write data to them. If these registers are allocated to the transmission queue, write data only to transmission buffers p (p = m × 16 + 15) for the corresponding channel m (m = 0, 1).

Address(es): RSCAN.RSCAN0TMDF10 A007 900Ch, RSCAN.RSCAN0TMDF11 A007 901Ch, RSCAN.RSCAN0TMDF12 A007 902Ch, RSCAN.RSCAN0TMDF13 A007 903Ch, RSCAN.RSCAN0TMDF14 A007 904Ch, RSCAN.RSCAN0TMDF15 A007 905Ch, RSCAN.RSCAN0TMDF16 A007 906Ch, RSCAN.RSCAN0TMDF17 A007 907Ch, RSCAN.RSCAN0TMDF18 A007 908Ch, RSCAN.RSCAN0TMDF19 A007 909Ch, RSCAN.RSCAN0TMDF110 A007 90ACh, RSCAN.RSCAN0TMDF111 A007 90BCh, RSCAN.RSCAN0TMDF112 A007 90CCh, RSCAN.RSCAN0TMDF113 A007 90DCh, RSCAN.RSCAN0TMDF114 A007 90ECh, RSCAN.RSCAN0TMDF115 A007 90FCh, RSCAN.RSCAN0TMDF116 A007 910Ch, RSCAN.RSCAN0TMDF117 A007 911Ch, RSCAN.RSCAN0TMDF118 A007 912Ch, RSCAN.RSCAN0TMDF119 A007 913Ch, RSCAN.RSCAN0TMDF120 A007 914Ch, RSCAN.RSCAN0TMDF121 A007 915Ch, RSCAN.RSCAN0TMDF122 A007 916Ch, RSCAN.RSCAN0TMDF123 A007 917Ch, RSCAN.RSCAN0TMDF124 A007 918Ch, RSCAN.RSCAN0TMDF125 A007 919Ch, RSCAN.RSCAN0TMDF126 A007 91ACh, RSCAN.RSCAN0TMDF127 A007 91BCh, RSCAN.RSCAN0TMDF128 A007 91CCh, RSCAN.RSCAN0TMDF129 A007 91DCh, RSCAN.RSCAN0TMDF130 A007 91ECh, RSCAN.RSCAN0TMDF131 A007 91FCh



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TMDB4[7:0]	Transmission Buffer Data Byte 4	Set the transmission buffer data.	R/W
b15 to b8	TMDB5[7:0]	Transmission Buffer Data Byte 5		R/W
b23 to b16	TMDB6[7:0]	Transmission Buffer Data Byte 6		R/W
b31 to b24	TMDB7[7:0]	Transmission Buffer Data Byte 7		R/W

35.2.54 Transmission Queue Configuration and Control Registers (RSCAN0TXQCCm) (m = 0, 1)

The RSCAN0TXQCCm registers control the settings for the transmission queue of each channel.

Address(es): RSCAN.RSCAN0TXQCC0 A007 83A0h, RSCAN.RSCAN0TXQCC1 A007 83A4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TXQIM	TXQIE	TXQDC[3:0]				—	—	—	—	—	—	—	TXQE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TXQE	Transmission Queue Enable	0: The transmission queue is not used. 1: The transmission queue is used.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b11 to b8	TXQDC[3:0]	Transmission Queue Depth Configuration	Setting these bits to g (g = 2 to 15) makes the (g + 1)-buffer transmission queue available. Setting these bits to 0 disables the transmission queue. Setting these bits to 1 is prohibited.	R/W
b12	TXQIE	Transmission Queue Interrupt Enable	0: Transmission queue interrupt is disabled. 1: Transmission queue interrupt is enabled.	R/W
b13	TXQIM	Transmission Queue Interrupt Source Select	0: When the transmission queue becomes empty upon completion of message transmission, a transmission queue interrupt request is generated. 1: A transmission queue interrupt request is generated each time a message has been transmitted.	R/W
b31 to b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TXQE Bit (Transmission Queue Enable)

Setting this bit to 1 makes the transmission queue available. Modify this bit in channel communication mode or channel halt mode. This bit is cleared to 0 in channel reset mode.

Before setting the TXQE bit to 1, set the TXQDC[3:0] bits to 0010b or more.

TXQDC[3:0] Bits (Transmission Queue Depth Configuration)

These bits are used to specify the number of transmission buffers to be allocated to the transmission queues. Transmission buffers are allocated to transmission queues in descending order of buffer number, that is, from 15 to 0 (CAN0) or 31 to 16 (CAN1), as shown in Table 35.10. For examples of how buffer allocation is done, see Figure 35.9 in section 35.6, Transmission Functions. Modify these bits only in channel reset mode.

Table 35.10 Transmission Buffers p Allocated to the Transmission Queue of Each Channel

	Transmission Buffers p Allocated to the Transmission Queue (p = 0 to 31)	
Settings of TXQDC[3:0] Bits	Channel 0 (m = 0)	Channel 1 (m = 1)
0000b	Setting prohibited	Setting prohibited
0001b	Setting prohibited	Setting prohibited
0010b	Transmission buffers 15 to 13	Transmission buffers 31 to 29
0011b	Transmission buffers 15 to 12	Transmission buffers 31 to 28
0100b	Transmission buffers 15 to 11	Transmission buffers 31 to 27
0101b	Transmission buffers 15 to 10	Transmission buffers 31 to 26
0110b	Transmission buffers 15 to 9	Transmission buffers 31 to 25
0111b	Transmission buffers 15 to 8	Transmission buffers 31 to 24
1000b	Transmission buffers 15 to 7	Transmission buffers 31 to 23
1001b	Transmission buffers 15 to 6	Transmission buffers 31 to 22
1010b	Transmission buffers 15 to 5	Transmission buffers 31 to 21
1011b	Transmission buffers 15 to 4	Transmission buffers 31 to 20
1100b	Transmission buffers 15 to 3	Transmission buffers 31 to 19
1101b	Transmission buffers 15 to 2	Transmission buffers 31 to 18
1110b	Transmission buffers 15 to 1	Transmission buffers 31 to 17
1111b	Transmission buffers 15 to 0	Transmission buffers 31 to 16

TXQIE Bit (Transmission Queue Interrupt Enable)

When the TXQIE bit is set to 1 and the source selected by the TXQIM bit occurs, a CANm transmission interrupt request (transmission queue interrupt) is generated.
Set the TXQE bit to 0 before modifying the TXQIE bit.

TXQIM Bit (Transmission Queue Interrupt Source Select)

This bit is used to select a transmission queue interrupt source. Modify this bit in channel reset mode.

35.2.55 Transmission Queue Status Registers (RSCAN0TXQSTSm) (m = 0, 1)

The RSCAN0TXQSTSm registers are status registers that indicate the state of the transmission queue.

Address(es): RSCAN.RSCAN0TXQSTS0 A007 83C0h, RSCAN.RSCAN0TXQSTS1 A007 83C4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	TXQIF	TXQFLL	TXQEMP
Value after reset:	0	0	0	x	x	x	x	x	0	0	0	0	0	0	0	1

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	TXQEMP	Transmission Queue Empty Status Flag	0: The transmission queue contains messages. 1: The transmission queue contains no message (transmission queue empty).	R
b1	TXQFLL	Transmission Queue Full Status Flag	0: The transmission queue is not full. 1: The transmission queue is full.	R
b2	TXQIF	Transmission Queue Interrupt Request Flag	0: No transmission queue interrupt request is present. 1: A transmission queue interrupt request is present.	R/W *1
b7 to b3	—	Reserved	These bits are read as 0.	R
b12 to b8	—	Reserved	These bits are read as an undefined value.	R
b31 to b13	—	Reserved	These bits are read as 0.	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

TXQEMP Flag (Transmission Queue Empty Status Flag)

The TXQEMP flag is cleared to 0 when even a single message is set for the transmission queue.
This flag is set to 1 in any of the following cases.

- The TXQE bit is set to 0 (the transmission queue is not used).
- The transmission queue becomes empty.
- In channel reset mode

TXQFLL Flag (Transmission Queue Full Status Flag)

The TXQFLL flag is set to 1 when the number of messages set for the transmission queue matches the transmission queue depth set by the TXQDC[3:0] bits in the RSCAN0TXQCCm register.
This flag is cleared to 0 in any of the following cases.

- The number of messages set for the transmission queue is smaller than the transmission queue depth set by the TXQDC[3:0] bits.
- In channel reset mode

TXQIF Flag (Transmission Queue Interrupt Request Flag)

The TXQIF flag is set to 1 when the event specified by the TXQIM bit in the RSCAN0TXQCCm register has occurred. The TXQIF flag is cleared to 0 in channel reset mode or by writing 0 to this flag. This flag is not cleared to 0 by setting the TXQE bit in the RSCAN0TXQCCm register to 0 (the transmission queue is not used).

35.2.56 Transmission Queue Pointer Control Registers (RSCAN0TXQPCTRm) (m = 0, 1)

The RSCAN0TXQPCTRm registers control the pointers to the transmission queue.

Address(es): RSCAN.RSCAN0TXQPCTR0 A007 83E0h, RSCAN.RSCAN0TXQPCTR1 A007 83E4h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	TXQPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TXQPC[7:0]	Transmission Queue Pointer Control	Writing FFh to these bits moves the write pointer to the transmission queue to the next queue buffer.	W
b31 to b8	—	Reserved	The write value should be 0.	W

TXQPC[7:0] Bits (Transmission Queue Pointer Control)

Writing FFh to the TXQPC[7:0] bits moves the write pointer to the next transmission queue buffer and generates a transmission request of the message. Write messages for transmission to the RSCAN0TMIDp, RSCAN0TMPTRp, RSCAN0TMDF0p, and RSCAN0TMDF1p registers (p = 15, 31) before writing FFh to the TXQPC[7:0] bits.
When writing FFh to these bits, make sure that the TXQE bit in the RSCAN0TXQCCm register is set to 1 (the transmission queue is used) and the TXQFLL flag in the RSCAN0TXQSTSm register is 0 (the transmission queue is not full).

35.2.57 Transmission History Configuration and Control Registers (RSCAN0THLCCm) (m = 0, 1)

The RSCAN0THLCCm registers control the settings for transmission history.

Address(es): RSCAN.RSCAN0THLCC0 A007 8400h, RSCAN.RSCAN0THLCC1 A007 8404h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	THLDTE	THLIM	THLIE	—	—	—	—	—	—	—	THLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	THLE	Transmission History Buffer Enable	0: Transmission history buffer is not used. 1: Transmission history buffer is used.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	THLIE	Transmission History Interrupt Enable	0: Transmission history interrupt is disabled. 1: Transmission history interrupt is enabled.	R/W
b9	THLIM	Transmission History Interrupt Source Select	0: When 12 sets of data have been stored in the transmission history buffer 1: When a single set of transmission history data has been stored	R/W
b10	THLDTE	Transmission History Target Buffer Select	0: Entry from transmission/reception FIFO buffers and transmission queue 1: Entry from transmission buffers, transmission/reception FIFO buffers, and transmission queue	R/W
b31 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

THLE Bit (Transmission History Buffer Enable)

Setting this bit to 1 makes the transmission history buffer available. When data transmission from the buffer selected by the THLDTE bit has been completed, the transmission history data of transmitted messages is stored in the transmission history buffer.

Modify this bit in channel communication mode or channel halt mode.

THLIE Bit (Transmission History Interrupt Enable)

When the THLIE bit is set to 1 and the source selected by the THLIM bit has occurred, a CANm transmission interrupt request (transmission history interrupt) is generated. Modify the THLIE bit only when the THLE bit set to 0.

THLIM Bit (Transmission History Interrupt Source Select)

This bit is used to select a transmission history interrupt source.

Modify this bit only in channel reset mode.

THLDTE Bit (Transmission History Target Buffer Select)

When this bit is set to 0, the transmission history data of messages transmitted from transmission/reception FIFO buffers and the transmission queue is stored in the transmission history buffer. When this bit is set to 1, the transmission history data of messages transmitted from transmission buffers, transmission/reception FIFO buffers, and the transmission queue is stored in the transmission history buffer.

Modify this bit only in channel reset mode.

35.2.58 Transmission History Status Registers (RSCAN0THLSTSm) (m = 0, 1)

The RSCAN0THLSTSm registers are status registers that indicate the state of transmission history.

Address(es): RSCAN.RSCAN0THLSTS0 A007 8420h, RSCAN.RSCAN0THLSTS1 A007 8424h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	THLMC[4:0]					—	—	—	—	THLIF	THLELT	THLFLL	THLEMP
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	THLEMP	Transmission History Buffer Empty Status Flag	0: Transmission history buffer contains unread data. 1: Transmission history buffer contains no unread data (buffer empty).	R
b1	THLFLL	Transmission History Buffer Full Status Flag	0: Transmission history buffer is not full. 1: Transmission history buffer is full.	R
b2	THLELT	Transmission History Buffer Overflow Flag	0: Transmission history buffer overflow has not occurred. 1: Transmission history buffer overflow has occurred.	R/W *1
b3	THLIF	Transmission History Interrupt Request Flag	0: No transmission history interrupt request is present. 1: A transmission history interrupt request is present.	R/W *1
b7 to b4	—	Reserved	These bits are read as 0.	R
b12 to b8	THLMC[4:0]	Transmission History Buffer Unread Data Counter	These bits indicate the number of unread data sets stored in the transmission history buffer.	R
b31 to b13	—	Reserved	These bits are read as 0.	R

Note 1. The only effective value for writing to this flag bit is 0, which clears the bit. Otherwise writing to the bit results in retention of its state.

THLEMP Flag (Transmission History Buffer Empty Status Flag)

The THLEMP flag is cleared to 0 when even a single set of transmission history data has been stored in the transmission history buffer.

This flag is set to 1 when all the data in the transmission history buffer has been read. This flag is also set to 1 in channel reset mode or when the THLE bit in the RSCAN0THLCCm register is set to 0 (the transmission history buffer is not used).

THLFLL Flag (Transmission History Buffer Full Status Flag)

The THLFLL flag is set to 1 when 16 data sets have been stored in the transmission history buffer, and is cleared to 0 when the number of data sets stored in the transmission history buffer has decreased to less than 16. This bit is also cleared to 0 in channel reset mode or when the THLE bit in the RSCAN0THLCCm register is set to 0 (the transmission history buffer is not used).

THLELT Flag (Transmission History Buffer Overflow Flag)

The THLELT flag is set to 1 when an attempt is made to store new transmission history data while the transmission history buffer is full. In this case, the new data is discarded. This flag becomes 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLIF Flag (Transmission History Interrupt Request Flag)

The THLIF flag is set to 1 when the interrupt source specified with the THLIM bit in the RSCAN0THLCCm register occurs.

This flag is cleared to 0 in channel reset mode or by the program writing 0 to this flag.

To clear the flags of the register to 0, the program must write 0 to the corresponding flag to be cleared.

When writing 0, using store instruction, set the bit to be set to “0” to “0”, and the bits not to be set to “0” to “1”.

THLMC[4:0] Bits (Transmission History Buffer Unread Data Counter)

These bits indicate the number of unread data sets stored in the transmission history buffer.

35.2.59 Transmission History Access Registers (RSCAN0THLACCm) (m = 0, 1)

The RSCAN0THLACCm registers are status registers that indicate the contents of the transmission history data held in the transmission history buffer.

Address(es): RSCAN.RSCAN0THLACC0 A007 9800h, RSCAN.RSCAN0THLACC1 A007 9804h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	TID[7:0]								—	BN[3:0]				BT[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	BT[2:0]	Buffer Type Data Indication	b2 b1 b0 0 0 1: Transmission buffer 0 1 0: Transmission/reception FIFO buffer 1 0 0: Transmission queue	R
b6 to b3	BN[3:0]	Buffer Number Data Indication	The buffer number of transmit source (transmission buffer, transmit/receive FIFO or transmission queue) can be read.	R
b7	—	Reserved	This bit is read as 0.	R
b15 to b8	TID[7:0]	Label Data Indication	The label information of stored data can be read.	R
b31 to b16	—	Reserved	These bits are read as 0.	R

BT[2:0] Bits (Buffer Type Data Indication)

These bits indicate the type of the transmit source buffer in the transmission history data stored in the transmission history buffer.

BN[3:0] Bits (Buffer Number Data Indication)

These bits indicate the transmit source buffer number in the transmission history data stored in the transmission history buffer.

TID[7:0] Bits (Label Data Indication)

These bits indicate the label information of transmission history data stored in the transmission history buffer.

35.2.60 Transmission History Pointer Control Registers (RSCAN0THLPCTRm) (m = 0, 1)

The RSCAN0THLPCTRm registers control the pointers to the transmission history buffer.

Address(es): RSCAN.RSCAN0THLPCTR0 A007 8440h, RSCAN.RSCAN0THLPCTR1 A007 8444h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	THLPC[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	THLPC[7:0]	Transmission History List Pointer Control	Writing FFh to these bits moves the read pointer to the next unread data in the transmission history buffer.	W
b31 to b8	—	Reserved	The write value should be 0.	W

THLPC[7:0] Bits (Transmission History List Pointer Control)

When the THLPC[7:0] bits are set to FFh, the read pointer moves to the next data in the transmission history buffer. At this time, the THLMC[4:0] (transmission history buffer unread data counter) value in the RSCAN0THLSTSm register is decremented. Write FFh to the THLPC[7:0] bits after reading from the RSCAN0THLACCm register.

When writing FFh to these bits, make sure that the THLE bit in the RSCAN0THLCCm register is set to 1 (the transmission history buffer is used) and the THLEMP flag in the RSCAN0THLSTSm register is 0.

35.2.61 Global Test Configuration Register (RSCAN0GTSTCFG)

The RSCAN0GTSTCFG register controls the test settings for the entire RSCAN module.
Modify the RSCAN0GTSTCFG register only in global test mode.

Address(es): RSCAN.RSCAN0GTSTCFG A007 8468h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b1	C1ICBCE	CAN1 Inter-Channel Communication Test Enable	0: CAN1 inter-channel communication test is disabled. 1: CAN1 inter-channel communication test is enabled.	R/W
b15 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b22 to b16	RTMPS[6:0]	RAM Test Page Configuration	Set a value within a range of page 0 (00h) to page 28 (1Ch).	R/W
b31 to b23	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

C0ICBCE Bit (CAN0 Inter-Channel Communication Test Enable)

Setting this bit to 1 enables the channel 0 inter-channel communication test.

C1ICBCE Bit (CAN1 Inter-Channel Communication Test Enable)

Setting this bit to 1 enables the channel 1 inter-channel communication test.

RTMPS[6:0] Bits (RAM Test Page Configuration)

These bits are used to set the RAM test target page number for RAM test. Set a value in the range of 00h to 1Ch, inclusive.

35.2.62 Global Test Control Register (RSCAN0GTSTCTR)

The RSCAN0GTSTCTR register controls operations for the RAM test and inter-channel communication test.

Address(es): RSCAN.RSCAN0GTSTCTR A007 846Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b0	ICBCTME	Inter-Channel Communication Test Enable	0: Inter-channel communication test disabled 1: Inter-channel communication test enabled	R/W
b1	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2	RTME	RAM Test Enable	0: RAM test is disabled. 1: RAM test is enabled.	R/W
b31 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ICBCTME Bit (Inter-Channel Communication Test Enable)

When this bit is set to 1, a communication test is enabled between the channels for which the CmICBCE bit (m = 0, 1) in the RSCAN0GTSTCFG register has been set to 1. Modify the ICBCTME bit only in global test mode.

RTME Bit (RAM Test Enable)

Setting this bit to 1 enables the RAM test. Modify this bit only in global test mode.

1. Set the GMDC[1:0] bits in the RSCAN0GCTR register to 10b (Global test mode).
2. Set the RTME bit to 1.
3. Check that the RTME bit is set to 1.

For writing the RTME bit, unlock the write protection on this bit by the global lock key register (RSCAN0GLOCKK).

35.2.63 Global Lock Key Register (RSCAN0GLOCKK)

The RSCAN0GLOCKK register unlocks protection of the special test bit and is write only.
For the protection unlock data, see section 35.9.4.2, Procedure for Unlocking the Protection.

Address(es): RSCAN.RSCAN0GLOCKK A007 847Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	LOCK[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	LOCK[15:0]	Lock Key	These bits are key bits to unlock protection of test mode.	W*1
b31 to b16	—	Reserved	The write value should be 0.	W

Note 1. Writing to these bits is effective only when the RSCAN module is in global test mode.

LOCK[15:0] Bits (Lock Key)

Writing the sequence of protection unlock data to the LOCK[15:0] bits enables writing 1 to the RTME bit in the RSCAN0GTSTCTR register.
After the protection has been unlocked, writing to the I/O register area (A007 8000h to A007 84FFh) of the CAN (i.e. to a location that is not in the RAM) leads to re-enabling of protection.
Reading from the I/O register area of the CAN or reading from or writing to other areas does not lead to re-enabling of protection.

35.2.64 RAM Test Page Access Registers (RSCAN0RPGACCr) (r = 0 to 63)

The RSCAN0RPGACCr register controls test access to RAM data.

Modify the RSCAN0RPGACCr register in global test mode with the RTME bit in the RSCAN0GTSTCTR register set to 1 (RAM test is enabled).

The RSCAN0RPGACCr register is readable and writable when the RTME bit is set to 1.

Address(es): RSCAN.RSCAN0RPGACC0 A007 9900h, RSCAN.RSCAN0RPGACC1 A007 9904h,

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	RDTA[31:0]	RAM Data Test Access	Data can be read and written in RSCAN RAM.	R/W

35.2.65 RSCAN ECC Control Register (ECCRCANCTL)

The ECCRCANCTL register controls the mode of the ECC for the RSCAN.
Bits 7 and 3 should be set (written) while the RSCAN is not operating.
Before writing to bit 7, set the EMCA1 and EMCA0 bits to 01b.

Address(es): RSCAN.ECCRCANCTL A007 B000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ECDEDF7	ECSEDF7	ECDEDF6	ECSEDF6	ECDEDF5	ECSEDF5	ECDEDF4	ECSEDF4	ECDEDF3	ECSEDF3	ECDEDF2	ECSEDF2	ECDEDF1	ECSEDF1	ECDEDF0	ECSEDF0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	EMCA1	EMCA0	—	—	ECOVFF	ECER2C	ECER1C	—	ECTHM	ECERVF	EC1ECP	EC2EDIC	EC1EDIC	ECER2F	ECER1F	ECEMF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECEMF	ECC Error Indication Flag	This flag indicates whether an error exists in the current read data. This bit is updated whenever the RAM reads data. This bit might be set if it is read before initialization of the RAM. This bit is cleared at the time of through mode enable selection (ECTHM = 1) and when there is no 1 bit error in the decode circuit input data. 0: The currently-read RAM data does not have bit errors. 1: The currently-read RAM data have bit errors.	R
b1	ECER1F	1-Bit Error Detection/Correction Flag	This flag indicates whether 1-bit error is detected during read access to the RAM when error detection is enabled (ECTHM = 0). Write 1 to the ECER1C bit (bit 9) to clear the flag. This bit is cleared at the time of through mode enable selection (ECTHM = 1). 0: 1-bit error has not occurred since this bit was cleared. 1: 1-bit error has occurred.	R
b2	ECER2F	2-Bit Error Detection Flag	This flag indicates whether 2-bit error is detected during read access to the RAM when error detection is enabled (ECTHM = 0). When 2-bit error interrupt is enabled (EC2EDIC = 1) and this flag is set, a 2-bit ECC error interrupt (INTECCDCNRAM) is output. Write 1 to the ECER2C bit (bit 10) to clear the flag. This bit is cleared at the time of through mode enable selection (ECTHM = 1). If 2-bit error is detected again while this bit is set, an interrupt signal will not be generated. 0: 2-bit error has not occurred since this bit was cleared. 1: 2-bit error has occurred.	R
b3	EC1EDIC	1-Bit Error Detection Interrupt Control	This bit controls whether to output a 1-bit ECC error source signal to the ECM when a 1-bit error is detected. 0: When a 1-bit error is detected, the error source signal is not output. 1: When a 1-bit error is detected, the error source signal is output.	R/W
b4	EC2EDIC	2-Bit Error Detection Interrupt Control	This bit controls whether to output a 2-bit ECC error source signal to the ECM when a 2-bit error is detected. 0: When a 2-bit error is detected, the error source signal is not output. 1: When a 2-bit error is detected, the error source signal is output.	R/W

Bit	Symbol	Bit Name	Description	R/W
b5	EC1ECP	1-Bit Error Correction Enable	This bit specifies whether to enable or disable 1-bit error correction when the ECC error detection/correction is enabled. 0: When a 1-bit error is detected, the error will be corrected. 1: When a 1-bit error is detected, the error will not be corrected.	R/W
b6	ECERVF	ECC Error Detection Enable Flag	This bit selects enabling or disabling of error detection. When writing to this bit, (0, 1) must be written to (EMCA1, EMCA0) at the same time. 0: Error detection is disabled. 1: Error detection is enabled.	R/W
b7	ECTHM	ECC Function Through Mode Select	This bit is used to set enabling and disabling of ECC. Setting this bit to 1 disables ECC. When writing to this bit, (0, 1) must be written to (EMCA1, EMCA0) at the same time. 0: Through mode is disabled (normal operation mode). 1: Through mode is enabled (ECC disabled).	R/W
b8	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b9	ECER1C	1-Bit ECC Error Correction Accumulation Flag Clear	This bit is used to clear the 1 bit error detection/correction flag of ECER1F (bit 1). This bit is always read as 0. Writing 0 is ignored. Write 1 to this bit while the ECER1F bit is set to clear the ECER1F bit. When a conflict between this bit writing and ECER1F bit setting occurs, writing to this bit is given priority.	R/W *1
b10	ECER2C	2-Bit ECC Error Detection Flag Clear	This bit is used to clear the 2 bit error detection flag of ECER2F (bit 2). This bit is always read as 0. Writing 0 is ignored. Write 1 to this bit while the ECER2F bit is set to clear the ECER2F bit. When a conflict between this bit writing and ECER2F bit setting occurs, writing to this bit is given priority.	R/W *1
b11	ECOVFF	ECC Overflow Detection Flag	When an ECC error is detected while all ECCRCANEADz registers (z = 0 to 7) hold addresses at which errors were detected, this bit is set and the RSCAN overflow error signal is output. 0: ECC overflow is not detected. 1: ECC overflow is detected.	R
b13, b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14	EMCA0	Access Control 0 to ECC Mode Selection	These bits specify whether modifying the ECTHM bit (bit 7) is disabled or enabled. The value written to these bits is not retained. When these bits are read, the read value is always 0. When these bits are 01b, writing to bits 7 and 6 is enabled.	R/W *1
b15	EMCA1	Access Control 1 to ECC Mode Selection		R/W *1
b31 to b16	ECDEDFz	2-Bit ECC Error Detection Flag	This flag bit indicates whether the error stored in the ECCRCANEADz register (z = 0 to 7) is a 2-bit error. 0: 2-bit error has not occurred. 1: 2-bit error has occurred.	R
	ECSEDFz	1-Bit ECC Error Detection Flag	This flag bit indicates whether the error stored in the ECCRCANEADz (z = 0 to 7) is a 1-bit error. 0: 1-bit error has not occurred. 1: 1-bit error has occurred.	R

Note 1. These bits are always read as 0.
Note: Bits 2 and 1 should be cleared when the ECC error indication flag (ECEMF) is not set.
We recommend initializing the RAM before clearing bits 2 and 1.

ECERVF Bit (ECC Error Detection Enable Flag)

This bit selects enabling or disabling of error detection. When writing to this bit, (0, 1) must be written to (EMCA1, EMCA0) at the same time. Error detection is disabled when the ECTHM bit is set to enable through mode. Table 35.11 shows the relationship between the ECERVF and ECTHM bits and the error detection setting.

Table 35.11 ECERVF and ECTHM Bits and Error Detection Setting

ECTHM Bit	ECERVF Bit	Error Detection Setting
0	0	Error detection disabled
0	1	Error detection enabled
1	0	Error detection disabled (through mode)
1	1	Error detection disabled (through mode)

ECOVFF Bit (ECC Overflow Detection Flag)

When a further ECC error is detected while all ECCRCANEADz registers (z = 0 to 7) hold addresses at which errors were detected, this bit is set and the RSCAN overflow error signal is output to the error control module (ECM). For details of the ECM, see section 42, Error Control Module (ECM).
Furthermore, if an overflow error is detected while this bit is set to 1, the RSCAN overflow error signal is output again.
This bit is cleared by writing 1 to both the ECER2C and ECER1C bits.

ECDEDFz Bit (2-Bit ECC Error Detection Flag) (z = 0 to 7)

This flag bit indicates the detection of 2-bit ECC errors and the address where the error was found is stored in the ECCRCANEADz register.
When an ECC overflow is detected (i.e., the ECOVFF bit = 1), this bit is not set even if the error is a 2-bit error.
This bit is cleared by writing 1 to both the ECER2C and ECER1C bits.

ECSEDFz Bit (1-Bit ECC Error Detection Flag) (z = 0 to 7)

This flag bit indicates the detection of 1-bit ECC errors and the address where the error was found is stored in the ECCRCANEADz register.
When an ECC overflow is detected (i.e., the ECOVFF bit = 1), this bit is not set even if the error is a 1-bit error.
This bit is cleared by writing 1 to both the ECER2C and ECER1C bits.

35.2.66 RSCAN ECC Error Address Register z (ECCRCANEADz) (z = 0 to 7)

ECCRCANEADz (z = 0 to 7) are read-only registers that automatically store and retain the values of addresses where ECC errors have occurred. If an ECC error occurs while ECC error detection is enabled, the buffer RAM addresses where errors are found are captured in order from z = 0.

Note 1. If an ECC error is detected again at the same address as that currently stored in the ECCRCANEADz register, the detected address is simply discarded.

Note 2. When 1-bit errors occur multiple times and all ECCRCANEADz registers hold only addresses where 1-bit errors were detected, if an overflow occurs due to the detection of a 2-bit error, the ECCRCANEAD7 register is overwritten with the address where the 2-bit error was detected and the value is retained.
Even if all ECCRCANEADz registers overflow due to the detection of a 1-bit error while only the addresses where 2-bit errors were detected are being held, the address where a 1-bit error was detected is discarded.

Address(es): RSCAN.ECCRCANEAD0 A007 B010h, RSCAN.ECCRCANEAD1 A007 B014h, RSCAN.ECCRCANEAD2 A007 B018h, RSCAN.ECCRCANEAD3 A007 B01Ch, RSCAN.ECCRCANEAD4 A007 B020h, RSCAN.ECCRCANEAD5 A007 B024h, RSCAN.ECCRCANEAD6 A007 B028h, RSCAN.ECCRCANEAD7 A007 B02Ch

	—	—	—	—	—	ECEADz[10:0]										
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b10 to b0	ECEADz [10:0]	ECC Error Address Storage	When an ECC error is detected in the buffer RAM of the RSCAN, the RAM address where the error was detected is stored and retained in these bits. The ECCRCANCTL.ECDEDFz and ECSEDFz bits can be used to judge whether the ECC error at the address was a 1-bit error or 2-bit error.	R
b31 to b11	—	Reserved	These bits are read as 0.	R

35.3 Interrupt Sources

The RSCAN module has 8 interrupt signals connected to the interrupt controller, and these are grouped into global interrupts and channel interrupts. Also, multiple interrupt sources in the RSCAN module are grouped into each of these 8 interrupt signals. Table 35.12 lists the CAN interrupt sources.

- Global interrupts (2 sources):
  1. CAN receive FIFO interrupt
  2. CAN global error interrupt
- Channel interrupts (3 sources for each channel m, 6 in total) (m = 0, 1):
  1. CANm transmit interrupt
     - CANm transmission complete interrupt
     - CANm transmission abort interrupt
     - CANm transmit/receive FIFO transmission complete interrupt (in transmission mode, gateway mode)
     - CANm transmission history interrupt
     - CANm transmission queue Interrupt
  2. CANm transmit/receive FIFO receive complete interrupt (in transmission mode, gateway mode)
  3. CANm error interrupt

When an interrupt request is generated, the corresponding interrupt request flag is set to 1 (interrupt request present). In that case, when the interrupt enable bit is set to 1 (enabling interrupts), an interrupt request is output from the RSCAN module to the interrupt controller. (Generation of interrupts also depends on the interrupt control register settings of the interrupt controller.)

Setting the interrupt request flag to 0 (no interrupt request present) or setting the interrupt enable bit to 0 (disabling interrupts) clears the current interrupt request. The current interrupt request is still output until the interrupt request flag is cleared.

Figure 35.2 shows the CAN global interrupt block diagram. Figure 35.3 shows the CAN channel interrupt block diagram.

Table 35.12 List of CAN Interrupt Sources

Interrupt Source			Corresponding Interrupt Request Flag	Corresponding Interrupt Enable Bit
Global interrupts	Receive FIFO	Receive FIFO 0	RFIF in the RSCAN0RFSTS0 register	RFIE in the RSCAN0RFCC0 register
		Receive FIFO 1	RFIF in the RSCAN0RFSTS1 register	RFIE in the RSCAN0RFCC1 register

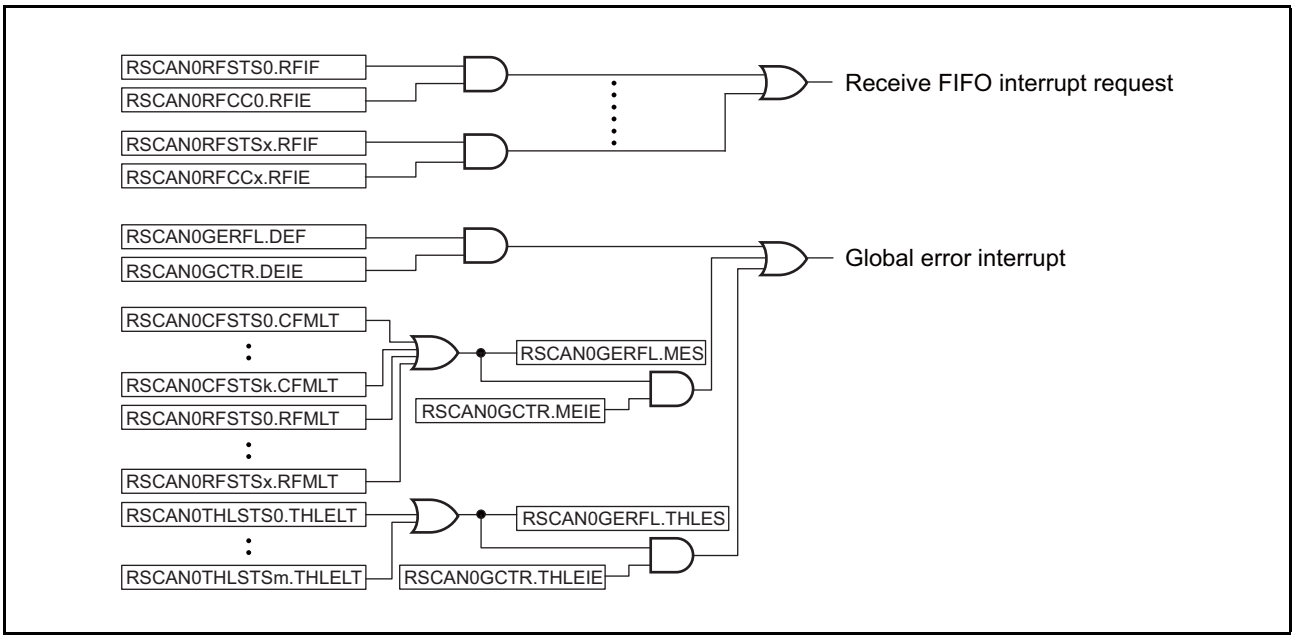

Figure 35.2 CAN Global Interrupt Block Diagram

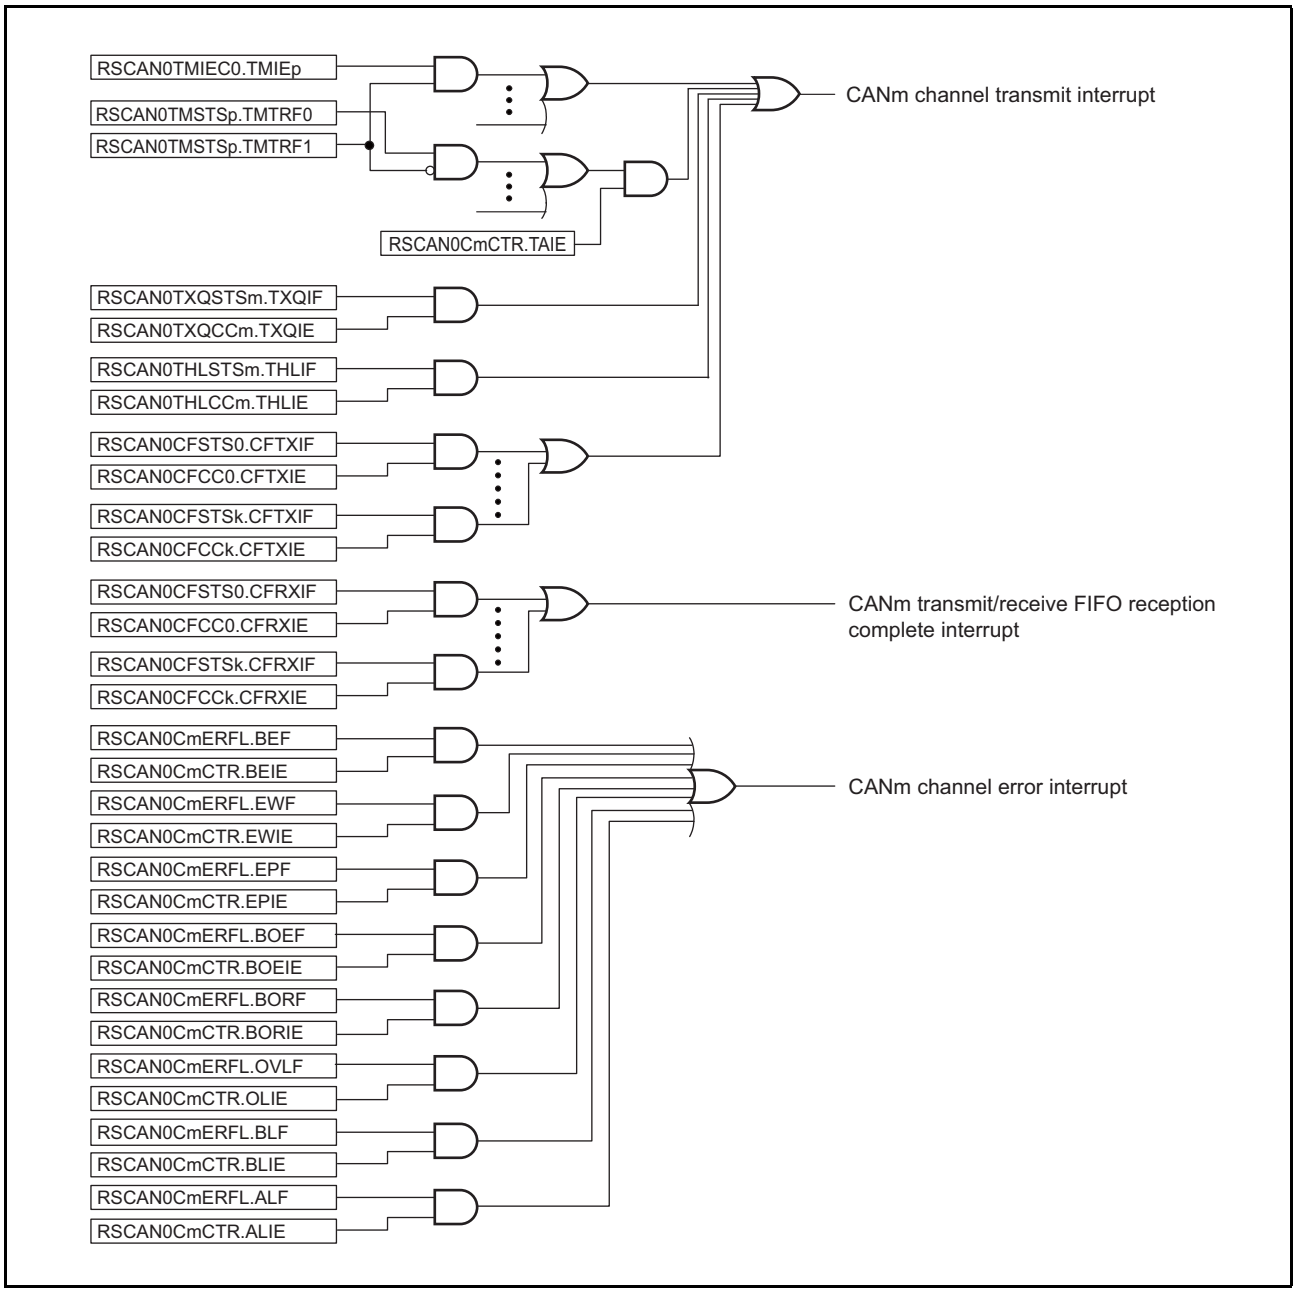

Figure 35.3 CAN Channel Interrupt Block Diagram

35.4 CAN Modes

The RSCAN module has four global modes to control the entire RSCAN module status and four channel modes to control individual channel status. Details of global modes are described in section 35.4.1, Global Modes, and details of channel modes are described in section 35.4.2, Channel Modes.

- Global stop mode: Stops the clocks of the entire module to achieve low power consumption.
- Global reset mode: Performs initial settings for the entire module.
- Global test mode: Performs test settings and performs the RAM test.
- Global operating mode: Makes the entire module operable.
- Channel stop mode: Stops the channel clock.
- Channel reset mode: Performs initial settings for the channels.
- Channel halt mode: Stops CAN communication and allows channel testing.
- Channel communication mode: Performs CAN communication.

35.4.1 Global Modes

Figure 35.4 shows the transitions of global modes.

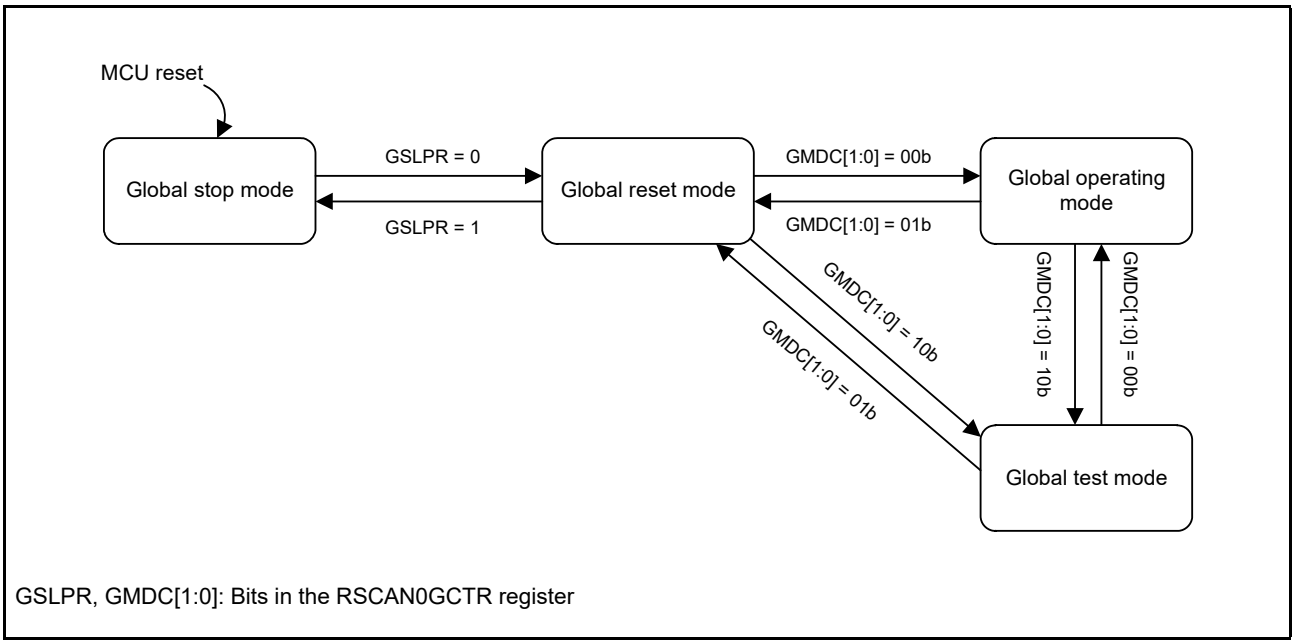

Figure 35.4 Transitions of Global Modes

In some cases, global mode transitions also force channel mode transitions. Table 35.13 shows the channel mode transitions depending on the global mode setting dictated by the GMDC[1:0] bits and the GSLPR bit.

Table 35.13 Transitions of Channel Modes Depending on Global Mode Setting (GMDC[1:0] and GSLPR Bits)

Channel Mode before Setting	Channel Mode after Setting			
	GMDC[1:0] = 00b GSLPR = 0 (Global Operation)	GMDC[1:0] = 10b GSLPR = 0 (Global Test)	GMDC[1:0] = 01b GSLPR = 0 (Global Reset)	GMDC[1:0] = 01b GSLPR = 1 (Global Stop)
Channel communication	Channel communication	Channel halt	Channel reset	Transition prohibited
Channel halt	Channel halt	Channel halt	Channel reset	Transition prohibited
Channel reset	Channel reset	Channel reset	Channel reset	Channel stop
Channel stop	Channel stop	Channel stop	Channel stop	Channel stop

Note 1. GMDC[1:0], GSLPR: Bits in the RSCAN0GCTR register

Table 35.14 shows the global mode transition time.

Table 35.14 Global Mode Transition Time

Mode before Transition	Mode after Transition	Maximum Transition Time
Global stop	Global reset	Three PCLKD cycles
Global reset	Global stop	Three PCLKD cycles
Global reset	Global test	Ten PCLKD cycles
Global reset	Global operating	Ten PCLKD cycles
Global test	Global reset	Three PCLKD cycles
Global test	Global operating	Three PCLKD cycles
Global operating	Global reset	Three PCLKD cycles
Global operating	Global test	Two CANm frames*1

Note 1. CANm frame (1 message) time of the lowest communication speed of the channels in use.

35.4.1.1 Global Stop Mode

In global stop mode, clocks of the CAN do not run and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained. Only the clock used by the CPU for writing to the GSLPR bit runs in this mode.

After the MCU is reset, the CAN module transitions to global stop mode. Setting the GSLPR bit in the RSCAN0GCTR register to 1 (in global stop mode) in global reset mode sets the CSLPR bit in each of the RSCAN0CmCTR registers (m = 0, 1) to 1 (channel stop mode). If all channels are forced to transition to channel stop mode, the CAN module transitions to global stop mode. The GSLPR bit should not be modified in global operating mode or global test mode.

35.4.1.2 Global Reset Mode

In global reset mode, RSCAN module settings are performed. When the RSCAN module transitions to global reset mode, some registers are initialized. Table 35.17 and Table 35.18 list the registers to be initialized.

Setting the GMDC[1:0] bits in the RSCAN0GCTR register to 01b sets the CHMDC[1:0] bits in each of the RSCAN0CmCTR registers (m = 0, 1) to 01b (channel reset mode). If all channels are forced to transition to channel reset mode, the CAN module transitions to global reset mode. Channels that are already in channel reset mode or channel stop mode do not transition (because the CHMDC[1:0] bits have already been set to 01b).

35.4.1.3 Global Test Mode

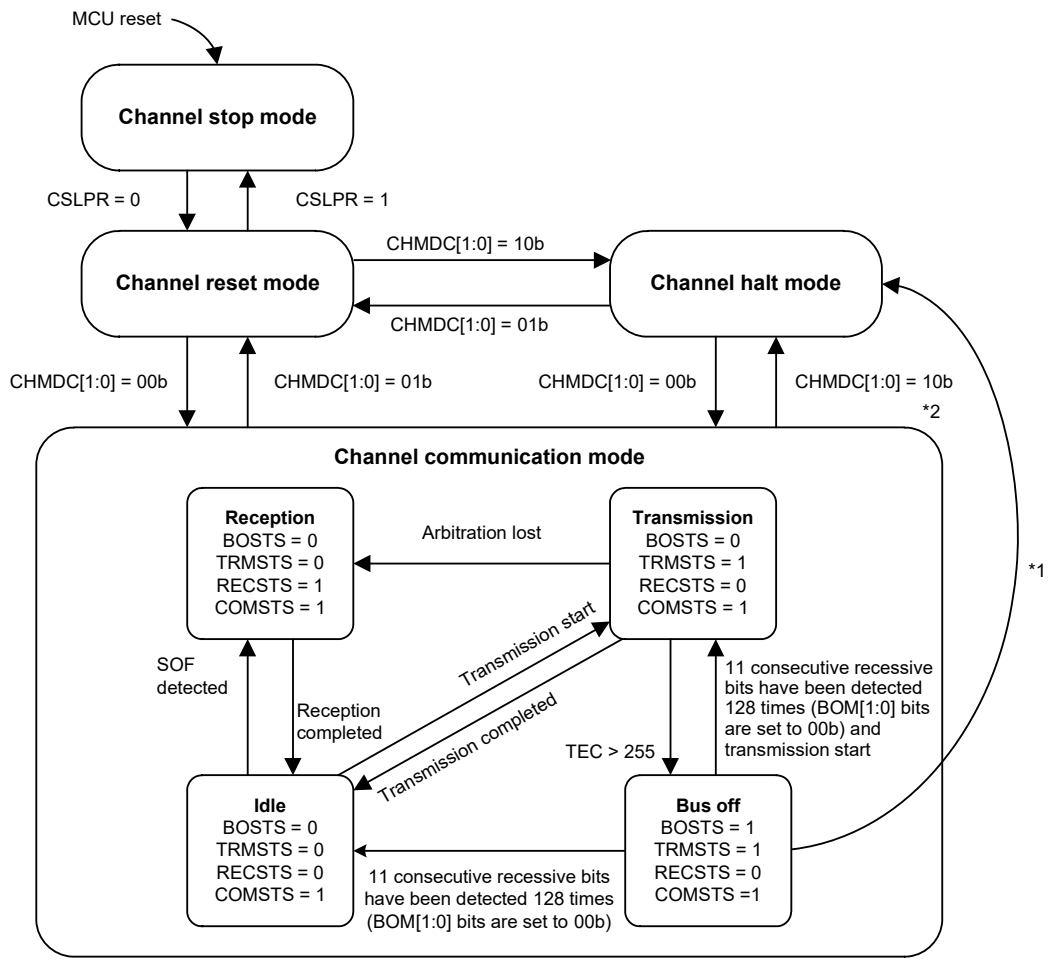
In global test mode, settings for test-related registers are performed. When the CAN module transitions to global test mode, all CAN communications are disabled.
Setting the GMDC[1:0] bits in the RSCAN0GCTR register to 10b sets the CHMDC[1:0] bits in each of the RSCAN0CmCTR registers to 10b (channel halt mode). If all channels are forced to transition to channel halt mode, the CAN module transitions to global test mode. Channels that are in channel stop mode, channel reset mode, or channel halt mode do not transition.

35.4.1.4 Global Operating Mode

The RSCAN module operates in global operating mode.
When the GMDC[1:0] bits in the RSCAN0GCTR register are set to 00b, the RSCAN module transitions to global operating mode.

35.4.2 Channel Modes

Figure 35.5 shows a channel mode state transition chart. Table 35.15 shows the channel mode transition time.



CHMDC[1:0], CSLPR, BOM[1:0]: Bits in the RSCAN0CmCTR register (m = 0, 1)
BOSTS, TRMSTS, RECSTS, COMSTS: Bits in the RSCAN0CmSTS register

Note 1. Timing of transition from bus off state to channel halt mode
- When BOM[1:0] = 01b: Transition to channel halt mode when TEC exceeds 255
- When BOM[1:0] = 10b: Transition to channel halt mode when 11 consecutive recessive bits have been detected 128 times
- When BOM[1:0] = 11b: Transition to channel halt mode when the CHMDC[1:0] bits are set to 10b

Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode.

Figure 35.5 Channel Mode State Transition Chart

Table 35.15 Channel Mode Transition Time

Mode before Transition	Mode after Transition	Maximum Transition Time
Channel stop	Channel reset	Three PCLKD cycles
Channel reset	Channel stop	Three PCLKD cycles
Channel reset	Channel halt	Three CANm bit times
Channel reset	Channel communication	Two CANm bit times
Channel halt	Channel reset	Three PCLKD cycles
Channel halt	Channel communication	Three CANm bit times
Channel communication	Channel reset	Three PCLKD cycles
Channel communication	Channel halt	Two CANm frames (1 message)

35.4.2.1 Channel Stop Mode

In channel stop mode, clocks are not supplied to channels and therefore power consumption is reduced. CAN registers can be read, but writing data to them is prohibited. Register values are retained.
Each channel enters channel stop mode after the MCU is reset. Channels also transition to channel stop mode when the GSLPR bit in the RSCAN0CmCTR register (m = 0, 1) is set to 1 (channel stop mode) in channel reset mode. The GSLPR bit should not be modified in channel communication mode and channel halt mode.

35.4.2.2 Channel Reset Mode

In channel reset mode, channel settings are performed. When a channel transitions to channel reset mode, some channel-related registers are initialized. Table 35.17 lists the registers to be initialized.
When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 01b (channel reset mode) during CAN communication, communication is terminated before it is completed and the channel transitions to channel reset mode. Table 35.16 shows the operation when the CHMDC[1:0] bits are set to 01b (channel reset mode) during CAN communication.

35.4.2.3 Channel Halt Mode

In channel halt mode, settings for test-related registers of channels are performed. When a channel transitions to channel halt mode, CAN communication of the channel stops.
Table 35.16 shows operation when the CHMDC[1:0] bits are set to 10b (channel halt mode) during CAN communication.

Table 35.16 Operation a Channel Transitions to Channel Reset Mode/Channel Halt Mode

Mode	During Reception	During Transmission	Bus Off State
Channel reset (CHMDC[1:0] = 01b)	Transitions to channel reset mode before reception is completed.*1	Transitions to channel reset mode before transmission is completed.*1	Transitions to channel reset mode before bus off recovery.
Channel halt*3 (CHMDC[1:0] = 10b)	Transitions to channel halt mode after reception is completed.*2	Transitions to channel halt mode after transmission is completed.	[When BOM[1:0] = 00b] Transitions to channel halt mode (CHMDC[1:0] = 10b) only after bus off recovery. [When BOM[1:0] = 01b] Transitions to channel halt mode automatically when the condition for transition to bus off state is met. [When BOM[1:0] = 10b] Transitions to channel halt mode automatically after bus off recovery. [When BOM[1:0] = 11b] Transitions to channel halt mode immediately after the CHMDC[1:0] bits are set to 10b before bus off recovery.

Note 1. To allow transition to channel reset mode after communication is completed, set the CHMDC[1:0] bits to 10b and confirm that communication has been completed and transition to channel halt mode has been made, and then set the CHMDC[1:0] bits to 01b.
Note 2. While the CAN bus is locked at the dominant level, transition to channel halt mode is not made. In that case, enter channel reset mode. The CAN bus status can be confirmed with the BLF flag of the RSCAN0CmERFL register that becomes 1 when dominant lock is detected.
Note 3. When the transition from channel reset mode to channel wait mode is to be made, set the RSCAN0CmCFG register in channel reset mode and then shift to channel wait mode.

35.4.2.4 Channel Communication Mode

In channel communication mode, CAN communication is performed. Each channel has the following communication states during CAN communication.

- Idle: Neither reception nor transmission is in progress.
- Reception: Receiving a message sent from another node.
- Transmission: Transmitting a message.
- Bus off: Isolated from CAN communication.

When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 00b, the channel transitions to channel communication mode. After that, once 11 consecutive recessive bits have been detected, the COMSTS flag in the RSCAN0CmSTS register (m = 0, 1) is set to 1 (communication is ready) and transmission and reception are enabled on the CAN network as an active node. At this time, transmission and reception of messages can be started.

35.4.2.5 Bus Off State

A channel transitions to the bus off state according to the transmit/receive error counter increment/decrement rules of the CAN specifications.
The conditions for returning from the bus off state are determined by the BOM[1:0] bits in the RSCAN0CmCTR register (m = 0, 1).

- When BOM[1:0] = 00b:
  Bus off recovery is compliant with the CAN specifications. After 11 consecutive recessive bits have been detected 128 times, a channel returns from the bus off state to the CAN communication ready state (error active state). At that time, the TEC[7:0] and REC[7:0] bits in the RSCAN0CmSTS register are initialized to 00h, the BORF flag in the RSCAN0CmERFL register is set to 1 (bus off recovery is detected), and a CANm error interrupt request (bus off recovery interrupt) is generated. When the CHMDC[1:0] bits in the RSCAN0CmCTR register are set to 10b (channel halt mode) in the bus off state, the channel transitions to channel halt mode after bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times).
- When BOM[1:0] = 01b:
  When a channel transitions to the bus off state, the CHMDC[1:0] bits are set to 10b and the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00h, but the BORF flag is not set to 1. Also, a bus off recovery interrupt request is not generated.
- When BOM[1:0] = 10b:
  When a channel has transitioned to the bus off state, the CHMDC[1:0] bits are set to 10b. After bus off recovery has been completed (11 consecutive recessive bits have been detected 128 times), the channel transitions to channel halt mode. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00h, the BORF flag is set to 1, and a CANm error interrupt request (bus off recovery interrupt) is generated.
- When BOM[1:0] = 11b:
  When the CHMDC[1:0] bits are set to 10b in the bus off state, the channel transitions to channel halt mode before bus off recovery is completed. At that time, the TEC[7:0] and REC[7:0] bits are initialized to 00h, but the BORF flag is not set to 1. Also, a bus off recovery interrupt is not generated.
  However, the BORF flag becomes 1 and a CANm error interrupt request (bus off recovery interrupt) is generated if a CAN module transitions to error active state (by detecting 128 times of 11 consecutive recessive bits) before CHMDC[1:0] bits are set to 10b.

If the RSCAN module causes the channel to transition to channel halt mode simultaneously with a program write to the CHMDC[1:0] bits, the program write takes precedence. An automatic transition to channel halt mode when the BOM[1:0] bits are set to 01b or 10b is made only when the CHMDC[1:0] bits are 00b (channel communication mode).
Furthermore, setting the RTBO bit in the RSCAN0CmCTR register to 1 allows a forced return from the bus off state. As soon as the RTBO bit is set to 1, the state changes to the error active state. After 11 consecutive recessive bits have been detected, the CAN module becomes ready for communication. In this case, the BORF flag is not set to 1 and the TEC[7:0] and REC[7:0] bits are initialized to 00h. Write 1 to the RTBO bit only when the BOM[1:0] value is 00b. Writing the RTBO bit to 1 in a state other than the bus off state is ignored, and the RTBO bit is immediately set to 0.

Table 35.17 Registers Initialized in Global Reset Mode or Channel Reset Mode

Register	Bit / Flag
RSCAN0CmCTR register	CTMS[1:0], CTME, CHMDC[1:0]
RSCAN0CmSTS register	CHLTSTS, EPSTS, BOSTS, TRMSTS, RECSTS, COMSTS, REC[7:0], TEC[7:0]
RSCAN0CmERFL register	CRCREG[14:0], ADERR, B0ERR, B1ERR, CERR, AERR, FERR, SERR, ALF, BLF, OVLF, BORF, BOEF, EPF, EWF, BEF
RSCAN0CFCCk register	When transmission/reception FIFO buffer is in transmission mode or gateway mode: CFE
RSCAN0CFSTSk register	When transmission/reception FIFO buffer is in transmission mode or gateway mode: CFMC[7:0], CFFLL, CFEMP, CFMLT, CFRXIF, CFTXIF
RSCAN0CFTISTS register	CFkTXIF
RSCAN0TMCp register	TMOM, TMTAR, TMTR
RSCAN0TMSTSp register	TMTARM, TMTRM, TMTRF[1:0], TMTSTS
RSCAN0TMTRSTS0 register	TMTRSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTARSTS0 register	TMTARSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTCSTS0 register	TMTCSTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TMTASTS0 register	TMTASTSp (Bits of corresponding channel are initialized in channel reset mode.)
RSCAN0TXQCCm register	TXQE
RSCAN0TXQSTSm register	TXQIF, TXQFLL, TXQEMP
RSCAN0THLCCm register	THLE
RSCAN0THLSTSm register	THLMC[4:0], THLIF, THLELT, THLFLL, THLEMP
RSCAN0GTINTSTS0 register	TSIFm, TAIFm, TQIFm, CFTIFm, THIFm (m = 0, 1)

Note 1. Number of channels: m = 0, 1
Note 2. Transmission/reception FIFO buffer: k = 0 to 2 (channel 0), 3 to 5 (channel 1)
Note 3. Transmission buffer number: p = 0 to 15 (channel 0), 16 to 31 (channel 1)

Table 35.18 Registers Initialized Only in Global Reset Mode

Register	Bit / Flag
RSCAN0GSTS register	GHLTSTS
RSCAN0GERFL register	THLES, MES, DEF
RSCAN0GTSC register	TS[15:0]
RSCAN0RMND0 register	RMNSq
RSCAN0RFCCx register	RFE
RSCAN0RFSTSx register	RFMC[7:0], RFIF, RFMLT, RFFLL, RFEMP
RSCAN0CFCCk register	When transmission/reception FIFO buffer is in reception mode: CFE
RSCAN0CFSTSk register	When transmission/reception FIFO buffer is in reception mode: CFMC[7:0], CFFLL, CFEMP, CFTXIF, CFRXIF, CFMLT
RSCAN0FESTS register	CFkEMP, RFxEMP
RSCAN0FFSTS register	CFkFLL, RFxFLL
RSCAN0FMSTS register	CFkMLT, RFxMLT
RSCAN0RFISTS register	RFxIF
RSCAN0CFRISTS register	CFkRXIF
RSCAN0GTSTCFG register	RTMPS[6:0], C0ICBCE, C1ICBCE, C2ICBCE, C3ICBCE, C4ICBCE, C5ICBCE
RSCAN0GTSTCTR register	RTME, ICBCTME

Note 1. Reception buffer number: q = 0 to 15 (channel 0), 16 to 31 (channel 1)
Note 2. Reception FIFO buffer number: x = 0 to 7

35.5 Reception Function

There are two reception types.

- Reception by reception buffers:
  Zero to 31 reception buffers can be shared by all channels. Since messages stored in reception buffers are overwritten at each reception, the latest receive data can always be read.
- Reception by reception FIFO buffers and transmission/reception FIFO buffers (reception mode):
  Eight reception FIFO buffers can be shared by all channels and three dedicated transmission/reception FIFO buffers are provided for each channel. Messages of up to the number of buffer stages specified with the RFDC[2:0] and CFDC[2:0] bits can be stored in FIFO buffers and can be read sequentially from the oldest.

35.5.1 Data Processing Using the Reception Rule Table

Data processing using the reception rule table allows dispatching of selected messages to the specified buffer. Data processing includes acceptance filter processing, DLC filter processing, routing processing, label addition processing, and mirror function processing.

Up to 128 reception rules can be registered per channel and up to (64 × number of channels) total reception rules can be registered in the entire module. (Up to 128 reception rules can be registered in this module that has two channels.) Set reception rules for each channel. Reception rules cannot be shared with other channels. If reception rules are not set, no messages can be received. Figure 35.6 illustrates how reception rules are registered.

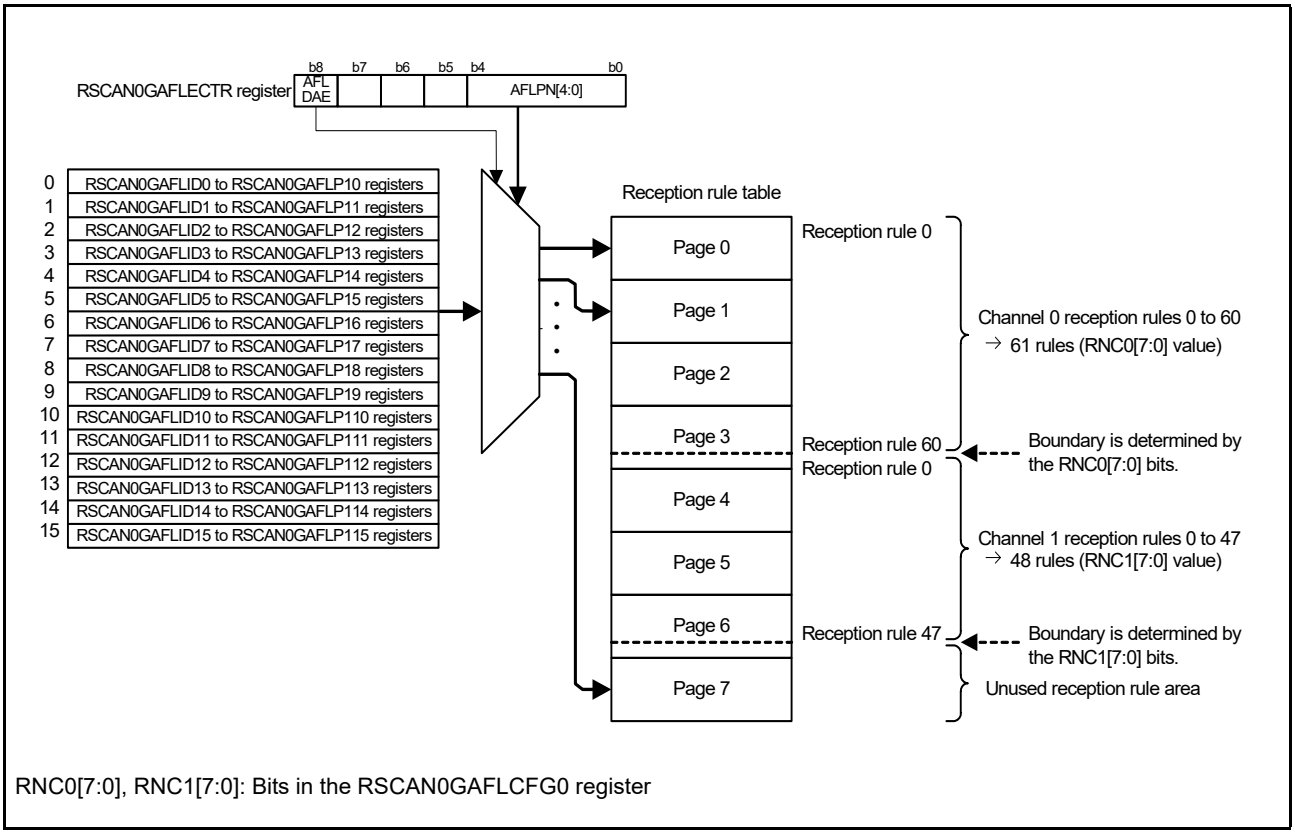


Figure 35.6 Entry of Reception Rules (for Setting Channels 0 and 1)

Note: Reception rules for each channel must be set in contiguous blocks.
Channel 1 rules and channel 0 rules must be set separately.

Each reception rule consists of 16 bytes in the RSCAN0GAFLIDj, RSCAN0GAFLMj, RSCAN0GAFLP0j, and RSCAN0GAFLP1j registers (j = 0 to 15). The RSCAN0GAFLIDj register is used to set GAFLID, GAFLIDE bit, GAFLRTR bit, and the mirror function, the RSCAN0GAFLMj register is used to set mask, the RSCAN0GAFLP0j register is used to set label information to be added, DLC value, and storage reception buffer, and the RSCAN0GAFLP1j register is used to set storage FIFO buffer. Up to 16 reception rules can be set per page.

35.5.1.1 Acceptance Filter Processing

In the acceptance filter processing, the ID data, IDE bit, and RTR bit in a received message are compared with the ID data, IDE bit, and RTR bit set in the reception rule of the corresponding channel. When all these bits match, the message passes through the acceptance filter processing. The ID data, IDE bit, and RTR bit in the received message which correspond to the bits set to 0 (bits are not compared) in the RSCAN0GAFLMj register are not compared and are regarded as matched.

Check begins with the reception rule of the minimum number for the corresponding channel. When all the bits to be compared in a received message match the bits set in the reception rule or when all the reception rules are compared without any match, filter processing stops. If there is no matching reception rule, the received message is not stored in the reception buffer or FIFO buffer.

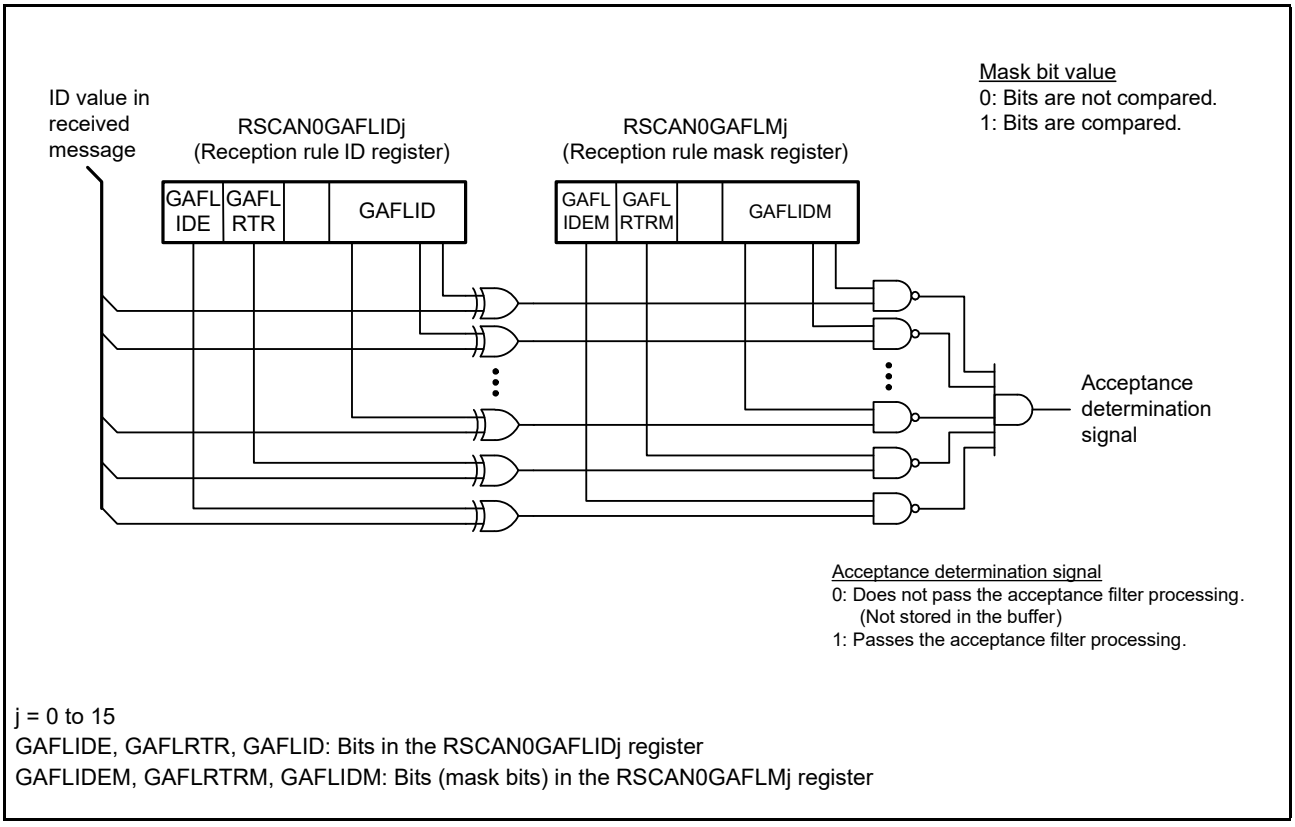

Figure 35.7 Acceptance Filter Function

35.5.1.2 DLC Filter Processing

When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), DLC filter processing is added to messages that passed through the acceptance filter processing. When the DLC value in a message is equal to or larger than the DLC value set in the reception rule, the message passes through the DLC filter processing.
When a message has passed through the DLC filter processing with the DRE bit in the RSCAN0GCFG register set to 0 (DLC replacement is disabled), the DLC value in the received message is stored in the buffer. In this case, all the data bytes in the received message are stored in the buffer.
When a message has passed through the DLC filter processing with the DRE bit in the RSCAN0GCFG register set to 1 (DLC replacement is enabled), the DLC value in the reception rule is stored in the buffer instead of the DLC value in the received message. In this case, a value of 00h is stored in each data byte beyond the number of bytes which is indicated by the DLC value in the reception rule.
When the DLC value in the received message is smaller than that in the reception rule, the message does not pass through the DLC filter processing. In this case, the message is not stored in the reception buffer or the FIFO buffer and the DEF flag in the RSCAN0GERFL register is set to 1 (a DLC error is present).

35.5.1.3 Routing Processing

Messages that passed through the acceptance filter processing and the DLC filter processing are stored in reception buffers, reception FIFO buffers, or transmission/reception FIFO buffers (set to reception mode or gateway mode). Message storage destination is set by the GAFLRMV and GAFLRMDP[6:0] bits in the RSCAN0GAFLP0j register (j = 0 to 15) and by the RSCAN0GAFLP1j register. Messages that passed through the acceptance filter processing and the DLC filter processing can be stored in up to eight buffers.

35.5.1.4 Label Addition Processing

It is possible to add 12-bit label information to messages that passed through the filter processing and store them in buffers. This label information is set in the GAFLPTR[11:0] bits in the RSCAN0GAFLP0j register.

35.5.1.5 Mirror Function Processing

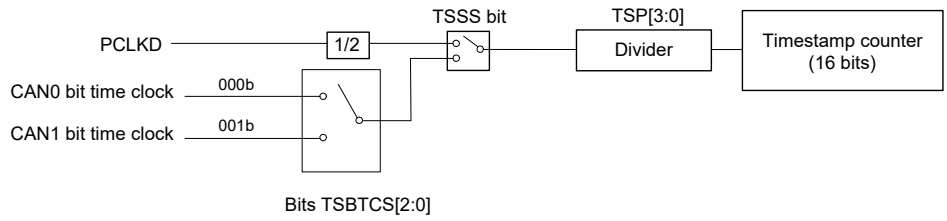
The mirror function allows the CAN node to receive its own transmitted messages. The mirror function is made available by setting the MME bit in the RSCAN0GCFG register to 1 (mirror function is enabled).
When the mirror function is in use, reception rules for which the GAFLLB bit in the RSCAN0GAFLIDj register is set to 0 are used for data processing when receiving messages transmitted from other CAN nodes. When the CAN node is receiving its own transmitted messages, reception rules for which the GAFLLB bit is set to 1 are used for data processing.

35.5.1.6 Timestamp

The timestamp counter is a 16-bit free-running counter used for recording message receive time. The timestamp counter value is fetched at the start-of-frame (SOF) timing of a message and is then stored in a reception buffer or a FIFO buffer together with the message ID and data. Either PCLKD/2 or the CANm bit time clock (m = 0, 1) may be selected as a timestamp counter clock source using the TSBTCS[2:0] and TSSS bits in the RSCAN0GCFG register. The timestamp counter count source is obtained by dividing the selected clock source by the TSP[3:0] value in the RSCAN0GCFG register.

When the CANm bit time clock is used as a clock source, the timestamp counter stops when the corresponding channel transitions to channel reset mode or channel halt mode. When the PCLKD/2 is used as a clock source, the timestamp function is not affected by channel mode.

The timestamp counter value is reset to 0000h by setting the TSRST bit in the RSCAN0GCTR register to 1.



TSBTCS[2:0], TSSS, TSP[3:0]: Bits in the RSCAN0GCFG register

Note: When specifying PCLKD/2 as the timestamp counter count source, set bits TSBTCS[2:0] to 000b.

Figure 35.8 Timestamp Function Block Diagram

35.6 Transmission Functions

There are three types of transmission.

- Transmission using transmission buffers:
  Each channel has 16 buffers.
- Transmission using transmission/reception FIFO buffers (transmission mode):
  Each channel has three FIFO buffers. Up to 128 messages can be contained in a single FIFO buffer. Each FIFO buffer is used with a link to a transmission buffer. Only the message to be transmitted next in a FIFO buffer becomes the target of transmit priority determination. Messages are transmitted sequentially on a first-in, first-out basis.
- Transmission using transmission queues:
  Up to 16 transmission buffers per channel can be allocated to the transmission queues. Transmission buffer ((16 × m) + 15) is used as an access window of a corresponding channel. Transmission buffers are allocated to transmission queues in descending order of buffer number. All messages in transmission queues, which are targets of priority determination, are transmitted in the order of ID number.

Table 35.19 Transmission Buffers p Allocated to Each Channel (p = 0 to 31)

Channel	Allocation of Transmission Buffers
CAN0	Transmission buffers 0 to 15
CAN1	Transmission buffers 16 to 31

Table 35.20 Transmission/Reception FIFO Buffers k Allocated to Each Channel (k = 0 to 5)

Channel	Allocation of Transmission Buffers
CAN0	Transmission/reception FIFO buffers 0 to 2
CAN1	Transmission/reception FIFO buffers 3 to 5

Figure 35.9 shows the allocation of transmission queues and transmission/reception FIFO buffer link.

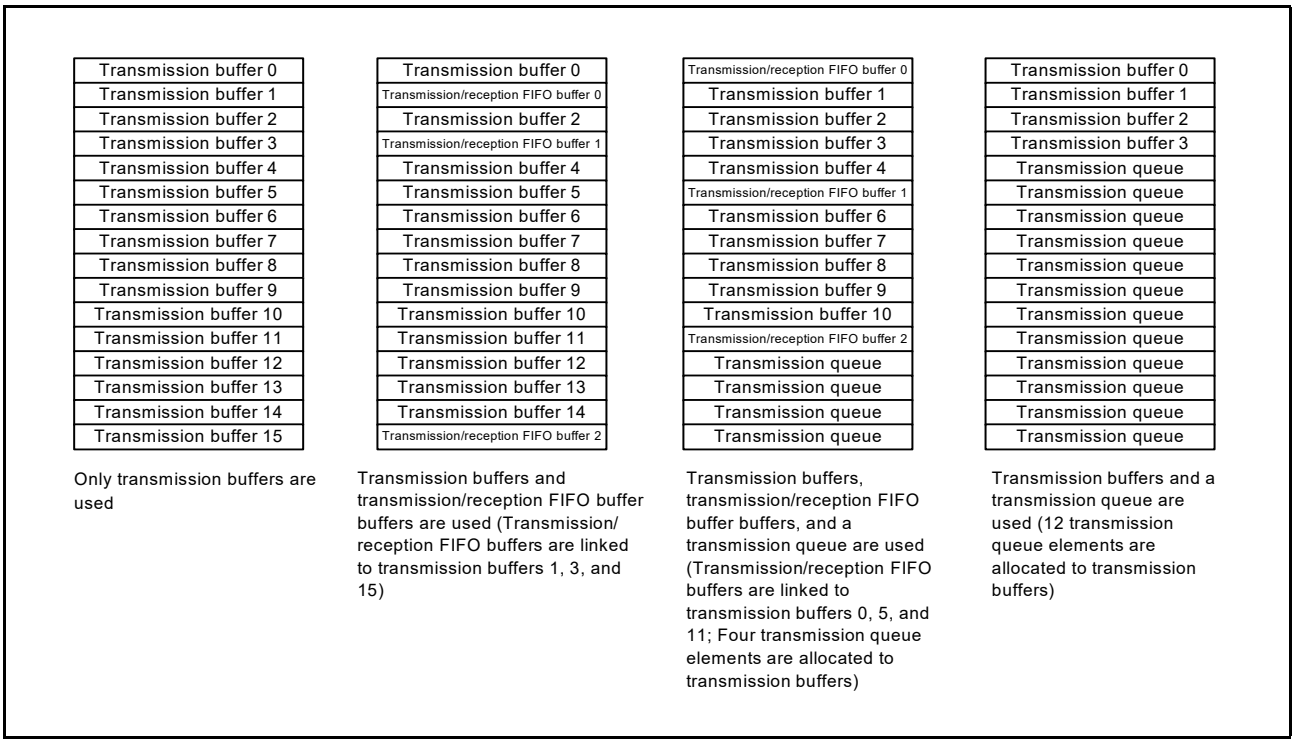


Figure 35.9 Allocation of Transmission Queues and Transmission/Reception FIFO Buffer Links

35.6.1 Transmit Priority Determination

If transmission requests are issued from multiple buffers or from the queue on the same channel, transmit priority is determined using one of the following methods.
The priority is determined by using one of the following methods.

- ID priority (TPRI bit = 0)
- Transmission buffer number priority (TPRI bit = 1)

All CAN channels use the setting of the TPRI bit in the RSCAN0GCFG register.
When the TPRI bit is set to 0, messages are transmitted according to the priority of stored message IDs. ID priority conforms to the CAN bus arbitration specification defined in the CAN specifications. All IDs of pending messages for transmission are targets of priority determination, regardless of whether they are stored in transmission buffers, transmission/reception FIFO buffers (set to transmission mode or gateway mode), or the transmission queue. If even a single transmission queue is used, select ID priority. When transmission/reception FIFO buffers are used, the oldest message in a FIFO buffer becomes the target of priority determination. When a message is being transmitted from a transmission/reception FIFO buffer, the next message in the FIFO buffer becomes the target of priority determination. When a transmission queue is used, all messages in the transmission queue are targets of priority determination. If the same ID is set for two or more buffers, the buffer with the smaller buffer number takes precedence.
When the TPRI bit is set to 1, the message in the transmission buffer with the minimum buffer number among all buffers with a transmission request is transmitted first. When transmission/reception FIFO buffers are linked to transmission buffers, transmit priority is determined according to linked transmission buffer numbers.
When messages are retransmitted due to an arbitration-lost or an error, transmit priority determination is made again regardless of the TPRI bit.

35.6.2 Transmission Using Transmission Buffers

Setting the transmission request bit (TMTR bit in the RSCAN0TMCp register) in a transmission buffer to 1 (transmission is requested) allows transmission of data frames or remote frames.
The transmission result is shown by the TMTRF[1:0] flag in the corresponding RSCAN0TMSTSp register (p = 0 to 31).
When transmission completes successfully, the TMTRF[1:0] flag is set to 10b (transmission has been completed (without transmission abort request)) or 11b (transmission has been completed (with transmission abort request)).

35.6.2.1 Transmission Abort Function

With respect to transmission buffers for which the TMTRM bit in the RSCAN0TMSTSp register is set to 1 (a transmission request is present), when the TMTAR bit in the RSCAN0TMCp register is set to 1 (transmission abort is requested), the transmission request is canceled. When transmission abort is completed, the TMTRF[1:0] flag in the RSCAN0TMSTSp register is set to 01b (transmission abort has been completed) and the transmission request is canceled (clearing the TMTRM bit to 0).
A message that is being transmitted or a message to be transmitted next according to the transmit priority determination cannot be aborted. However, when an arbitration-lost or an error occurs during transmission of a message for which the TMTAR bit is set to 1, retransmission is not performed.

35.6.2.2 One-Shot Transmission Function (Retransmission Disabling Function)

When the TMOM bit in the RSCAN0TMCp register is set to 1 (one-shot transmission is enabled), transmission is performed only once. Even if an arbitration-lost or an error occurs, retransmission is not performed.
The one-shot transmission result is shown by the TMTRF[1:0] flag in the corresponding RSCAN0TMSTSp register.
When one-shot transmission completes successfully, the TMTRF[1:0] flag is set to 10b or 11b. When an arbitration-lost or an error occurs, the TMTRF[1:0] flag is set to 01b (transmission abort has been completed).

35.6.3 Transmission Using FIFO Buffers

Multiple messages can be stored in a single transmission/reception FIFO buffers, up to the number specified by the FIFO buffer depth, which is set by the CFDC[2:0] bits in the RSCAN0CFCCk register (k = 0 to 5). Messages are transmitted sequentially on a first-in, first-out basis.
Each transmission/reception FIFO buffer is linked to a transmission buffer selected by the CFTML[3:0] bits in the RSCAN0CFCCk register. When the CFE bit in the RSCAN0CFCCk register is set to 1 (transmission/reception FIFO buffers are used), transmission/reception FIFO buffers become targets of transmit priority determination. Priority of only the next message for transmission is determined in the FIFO buffer.
When the CFE bit is set to 0 (no transmission/reception FIFO buffer is used), the CFEMP flag is set to 1 (the transmission/reception FIFO buffer contains no message (buffer empty)) at the timing below.

- The transmission/reception FIFO buffer becomes empty immediately if the message in it is not being transmitted or is not to be transmitted next.
- The transmission/reception FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost in the case that a message in it is being transmitted or to be transmitted next.

When the CFE bit is cleared to 0, all messages in transmission/reception FIFO buffers are lost and messages cannot be stored in FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

35.6.3.1 Interval Transmission Function

A message transmission interval time can be set to space the transmission of messages from the same FIFO buffer when using a transmission/reception FIFO buffer set to transmission mode or gateway mode.
Immediately after the first message has been transmitted successfully from the FIFO buffer with the CFE bit in the RSCAN0CFCCk register set to 1, the interval timer starts counting (after EOF7 of the CAN protocol). After that, when the interval time has passed, the next message is transmitted. The interval timer stops in channel reset mode or by clearing the CFE bit to 0.
The interval time is set by the CFITT[7:0] bits in the RSCAN0CFCCk register. When the interval timer is not used, set the CFITT[7:0] bits to 00h.
Select an interval timer count source using the CFITR and CFITSS bits in the RSCAN0CFCCk register. When the CFITR and CFITSS bits are set to 00b, the count source is obtained by dividing PCLKD/2 by the value of the ITRCP[15:0] bits. When the CFITR and CFITSS bits are set to 10b, the count source is obtained by dividing PCLKD/2 by (the value of the ITRCP[15:0] bits in the RSCAN0GCFG register × 10). When the CFITR and CFITSS bits are set to x1b, the CANm bit time clock is used as a count source.
The interval time is calculated by the following equations where M is the value of ITRCP[15:0] and N is the value of CFITT[7:0].

- When CFITR and CFITSS = 00b (fPBA is the frequency of PCLKD):

$$\frac{1}{f_{PBA}} \times 2 \times M \times N$$

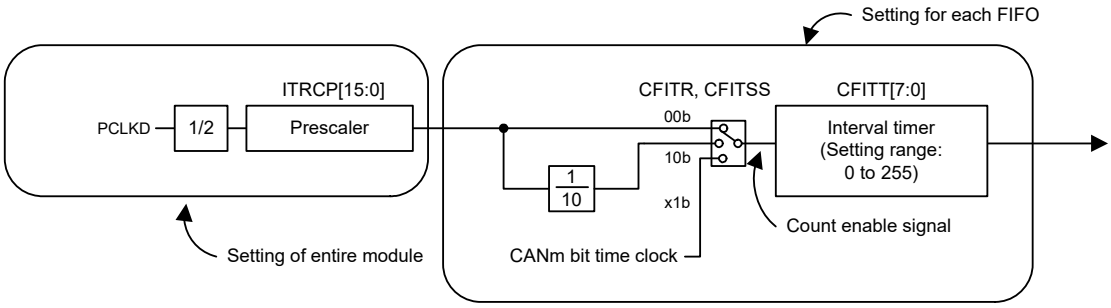
- When CFITR and CFITSS = 10b:

$$\frac{1}{f_{PBA}} \times 2 \times M \times 10 \times N$$

- When CFITR and CFITSS = x1b (fCANBIT is the frequency of CANm bit time clock):

$$\frac{1}{f_{CANBIT}} \times N$$

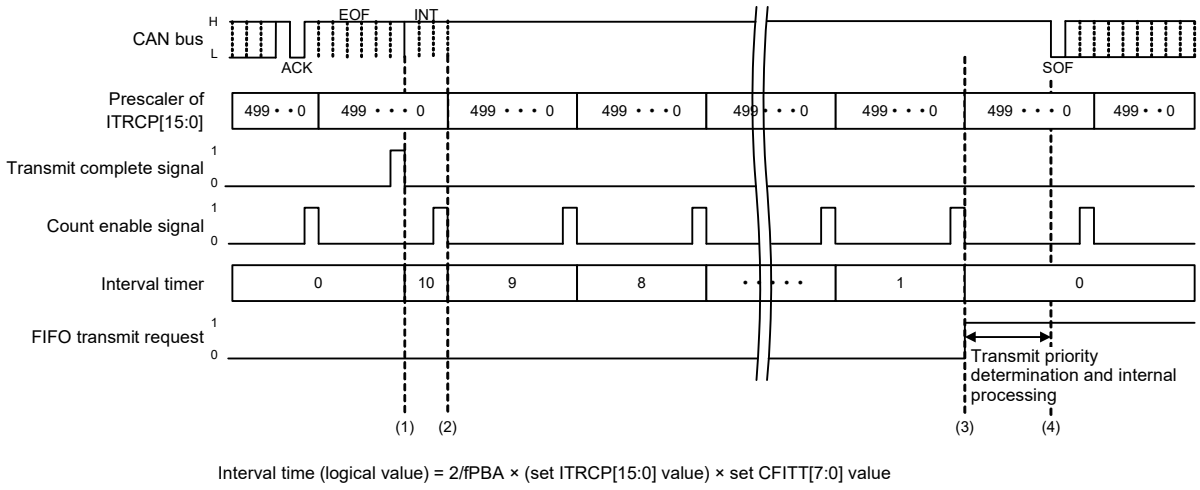
Figure 35.10 shows the interval timer block diagram.



ITRCP[15:0]: Bits in the RSCAN0GCFG register
CFITR, CFITSS, CFITT[7:0]: Bits in the RSCAN0CFCCk register
m = 0,1 , k = 0 to 5

Figure 35.10 Interval Timer Block Diagram

Figure 35.11 shows the interval timer timing diagram.



Interval time (logical value) = 2/fPBA × (set ITRCP[15:0] value) × set CFITT[7:0] value

fPBA: Frequency of PCLKD
ITRCP[15:0]: Bits in the RSCAN0GCFG register (The set value is 500 in this figure.)
CFITT[7:0]: Bits in the RSCAN0CFCCk register (The set value is 10 in this figure.)

Figure 35.11 Interval Timer Timing Chart

(1) The interval timer starts counting upon completion of transmission. Since the prescaler is not initialized at the time of transmission completion, the first interval time contains an error of up to one count of the interval timer.
(2) The interval timer is decremented by the next count enable signal.
(3) When the interval timer has decreased to 0, the transmission/reception FIFO buffer issues a transmission request.
(4) The transmission/reception FIFO buffer is determined for the next transmission by the priority determination, it starts transmitting data. Transmission starts usually with a delay of three CANm bit time clock cycles or less from the issue of transmission request. If multiple internal processes (such as receive filter processing, message routing, and transmit priority determination) take place in all channels, a delay of up to 582 cycles of the PCLKD may be generated.

35.6.4 Transmission Using Transmission Queues

Three to sixteen buffers are allocated to a transmission queue of each channel, and transmission buffer ((16 × m) + 15) (m = 0, 1) is used as an access window of a corresponding channel.
All messages in a transmission queue are targets of transmit priority determination and are transmitted in the ID priority order regardless of storage sequence. If two messages having the same ID are stored in a transmission queue, these messages are not always transmitted in the order of their storage in the transmission queue.
Setting the TXQE bit in the RSCAN0TXQCCm register to 0 disables transmission queues. When the TXQE bit is set to 0, the TXQEMP flag in the RSCAN0TXQSTSm register is set to 1 (the transmission queue contains no messages (transmission queue empty)) at the timing below.

- The transmission queue becomes empty immediately when no message in it is being transmitted or will be transmitted next.
- The transmission queue becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when a message in it is being transmitted or will be transmitted next.

When the TXQE bit is cleared to 0, all messages in transmission queues are lost and messages cannot be stored in transmission queues. Confirm that the TXQEMP flag is set to 1 before setting the TXQE bit to 1 again.

35.6.5 Transmission History Function

Information about transmission-completed messages can be stored in the transmission history buffer. Each channel has a single transmission history buffer that can contain 16 sets of transmission history data.
A message transmit source buffer type can be selected by the THLDTE bit in the RSCAN0THLCCm register. The THLEN bit in the RSCAN0CFIDk register (k = 0 to 5) determines whether transmission history data is stored for each message.
The following information on a transmitted message will be stored in the transmission history buffer after the successful completion of transmission.
Storage of the transmission history data after the successful completion of transmission may take up to 150 cycles of pclk.

- Buffer type 001b: Transmission buffer
  010b: Transmission/reception FIFO buffer
  100b: Transmission queue
- Buffer number Number of source transmission buffer, transmission queue, or transmission/reception FIFO buffer. This number depends on buffer types. See Table 35.21.
- Label data Label information of the transmitted message

Table 35.21 Transmission History Data Buffer Numbers

Buffer No. / Buffer type	001b	010b	100b
0000b	Transmission buffer 16 × m + 0	Buffer numbers of the transmission buffer linked to the transmission/ reception FIFO buffer by the CFTML[3:0] bits in the RSCAN0CFCCk register (k = 0 to 5)	Buffer numbers of the transmission buffer allocated to the transmit queue that performed transmission
0001b	Transmission buffer 16 × m + 1		
0010b	Transmission buffer 16 × m + 2		
0011b	Transmission buffer 16 × m + 3		
0100b	Transmission buffer 16 × m + 4		
0101b	Transmission buffer 16 × m + 5		
0110b	Transmission buffer 16 × m + 6		
0111b	Transmission buffer 16 × m + 7		
1000b	Transmission buffer 16 × m + 8		
1001b	Transmission buffer 16 × m + 9		
1010b	Transmission buffer 16 × m + 10		
1011b	Transmission buffer 16 × m + 11		
1100b	Transmission buffer 16 × m + 12		
1101b	Transmission buffer 16 × m + 13		
1110b	Transmission buffer 16 × m + 14		
1111b	Transmission buffer 16 × m + 15		

Label data is used to identify each message. Unique label data can be added to each message transmitted from a transmission buffer, transmission queue, or transmission/reception FIFO buffer.
Transmission history data can be read from the RSCAN0THLACCm register. If an attempt is made to store new transmission history data while the buffer is full, the buffer overflows and the new data is discarded.

35.7 Gateway Function

When a transmission/reception FIFO buffer is set to gateway mode, received messages can be transmitted from an arbitrary channel without CPU intervention.

When a transmission/reception FIFO buffer for which the CFM[1:0] bits in the RSCAN0CFCCk register are set to 10b (gateway mode) is selected by the RSCAN0GAFLP1j register (j = 0 to 15), messages that passed through the filter processing of the reception rule are stored in the specified transmission/reception FIFO buffer and are automatically transmitted from the buffer.

Messages stored in a transmission/reception FIFO buffer are transmitted sequentially on a first-in, first-out basis. Only the message to be transmitted next becomes the target of transmit priority determination.

Transmission/reception FIFO buffers in the gateway mode are disabled by setting the CFE bit in the RSCAN0CFCCk register to 0 and the CFEMP flag becomes 1 according to the timing below.

- The transmission/reception FIFO buffer becomes empty immediately when the message in it is not being transmitted and will not to be transmitted next.
- The transmission/reception FIFO buffer becomes empty after transmission completion, CAN bus error detection, or arbitration-lost when the message in it is being transmitted or will be transmitted next.

When the CFE bit is cleared to 0, all messages in transmission/reception FIFO buffers are lost and messages can no longer be stored in transmission/reception FIFO buffers. Confirm that the CFEMP flag is set to 1 before setting the CFE bit to 1 again.

35.8 Test Function

The test function is classified into communication tests and global tests.

- Communication tests: Performed for each channel.
  - Standard test mode
  - Listen-only mode
  - Self-test mode 0 (external loopback mode)
  - Self-test mode 1 (internal loopback mode)
- Global tests: Performed for the entire module
  - RAM test (read/write test)
  - Inter-channel communication test

35.8.1 Standard Test Mode

Standard test mode allows CRC test.

35.8.2 Listen-Only Mode

Listen-only mode allows reception of data frames and remote frames. Only recessive bits are transmitted on the CAN bus, and the ACK bit, overload flag, and active error flag are not transmitted.
Listen-only mode is available for detecting the communication speed.
Do not make a transmission request from any buffer or queue in listen-only mode.
Figure 35.12 shows the connection when listen-only mode is selected.

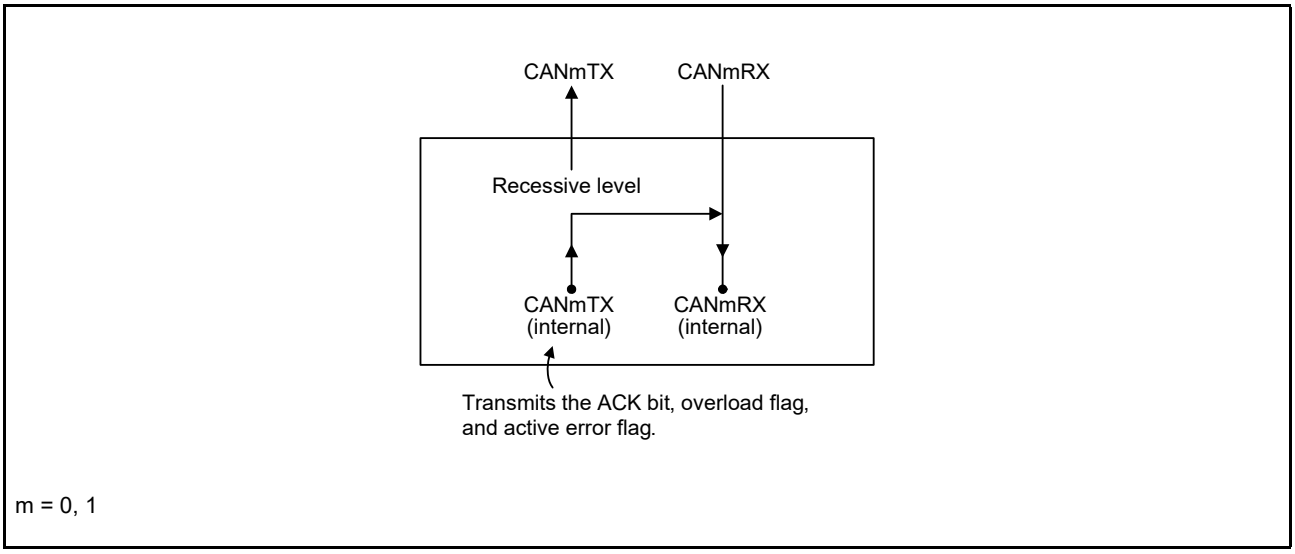


Figure 35.12 Connection when Listen-Only Mode is Selected

35.8.3 Self-Test Mode (Loopback Mode)

In self-test mode, transmitted messages are compared with the reception rule of the own channel and the messages are stored in a buffer if they have passed through the filter processing. Messages transmitted from other CAN nodes are compared only with the reception rule for which the GAFLLB bit in the RSCAN0GAFLIDj register (j = 0 to 15) is set to 0 (when a message transmitted from another CAN node is received).
If the mirror function and self-test mode are both enabled, the self-test mode setting takes precedence.

35.8.3.1 Self-Test Mode 0 (External Loopback Mode)

Self-test mode 0 is used to perform a loopback test within a channel including the CAN transceiver.
In self-test mode 0, transmitted messages are handled as messages received through the CAN transceiver and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.
Figure 35.13 shows the connection when self-test mode 0 is selected.

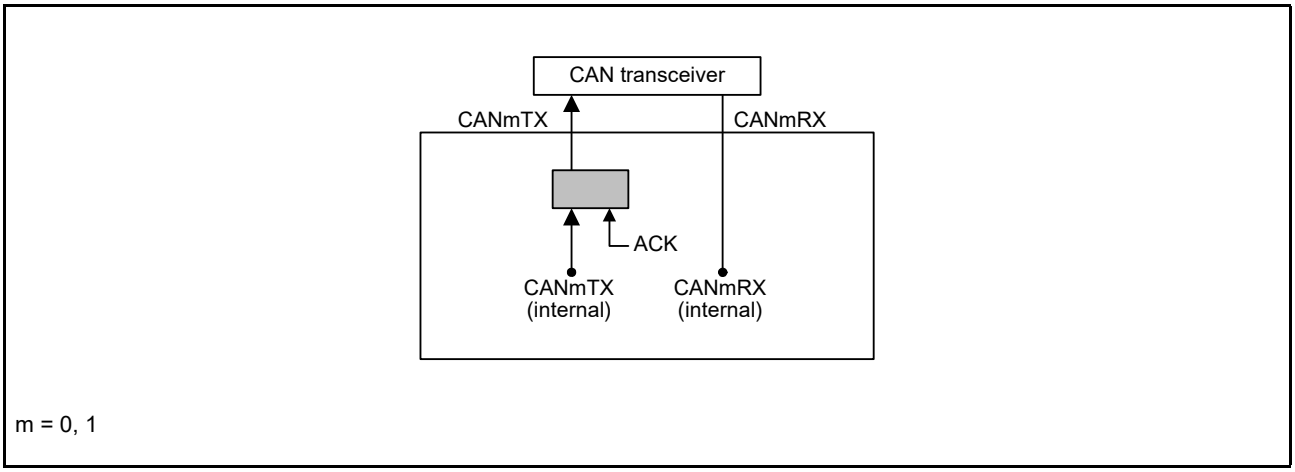

Figure 35.13 Connection when Self-Test Mode 0 is Selected

35.8.3.2 Self-Test Mode 1 (Internal Loopback Mode)

In self-test mode 1, transmitted messages are handled as received messages and are stored in a buffer. An ACK bit is generated to receive messages transmitted from the own CAN node.
In self-test mode 1, internal feedback from the internal CANmTX pin (m = 0, 1) to the internal CANmRX pin is performed. The external CANmRX pin input is isolated. The external CANmTX pin outputs only recessive bits.
Figure 35.14 shows the connection when self-test mode 1 is selected.

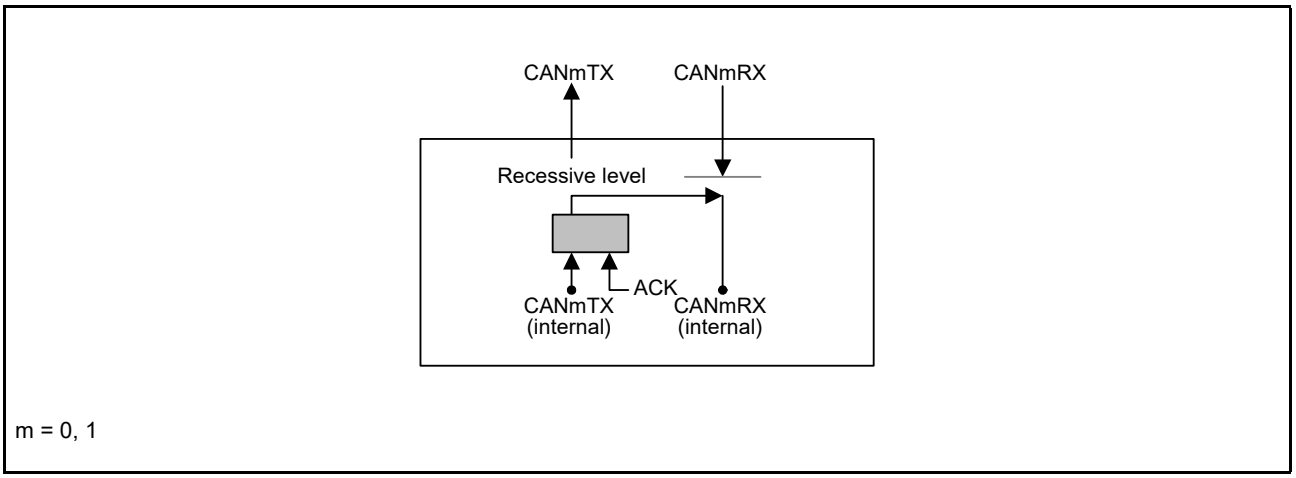

Figure 35.14 Connection when Self-Test Mode 1 is Selected

35.8.4 RAM Test

The RAM test function allows accesses to all CAN RAM addresses.
When the RAM test function is used, the RAM is divided into pages of 256 bytes each. RAM test page is set by the RTMPS[6:0] bits in the RSCAN0GTSTCFG register. Data in the set page can be read from and written to the RSCAN0RPGACCr register (r = 0 to 63). The available total RAM size is 14592 bytes (3900h).

35.8.5 Inter-Channel Communication Test

The inter-channel communication test function allows communication test by internally connecting CAN channels to each other. During this test, channels are isolated from the external CAN bus.
Before starting data transmission/reception in channel communication mode, make transmission/reception settings for each channel.
Figure 35.15 shows the connection for inter-channel communication test.

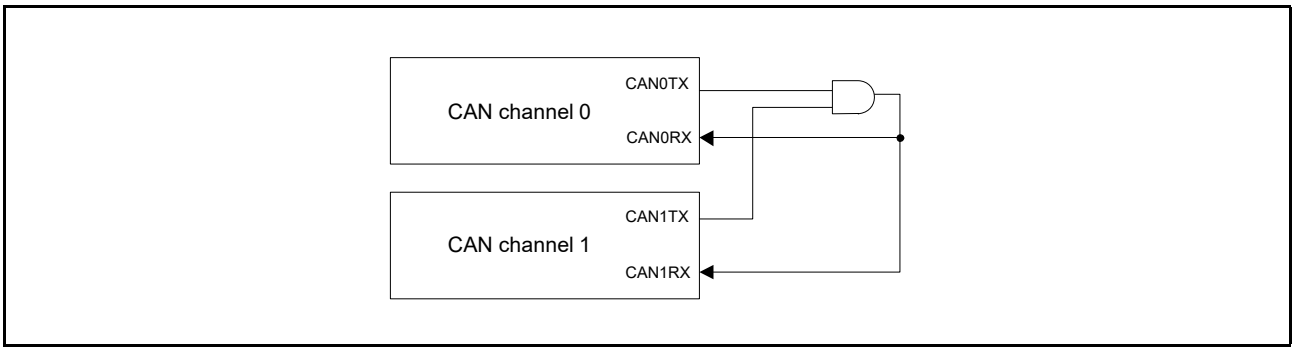

Figure 35.15 Connection for Inter-Channel Communication Test

35.9 RSCAN Setting Procedure

35.9.1 Initial Settings

The RSCAN module initializes the CAN RAM after the MCU is reset. The RAM initialization time is 7298 cycles of PCLKD. The GRAMINIT flag in the RSCAN0GSTS register is set to 1 (CAN RAM initialization is ongoing) during the RAM initialization and is cleared to 0 (CAN RAM initialization is finished) when the initialization is completed. Make CAN settings after the GRAMINIT flag is cleared to 0. Figure 35.16 shows the CAN setting procedure after the MCU is reset.

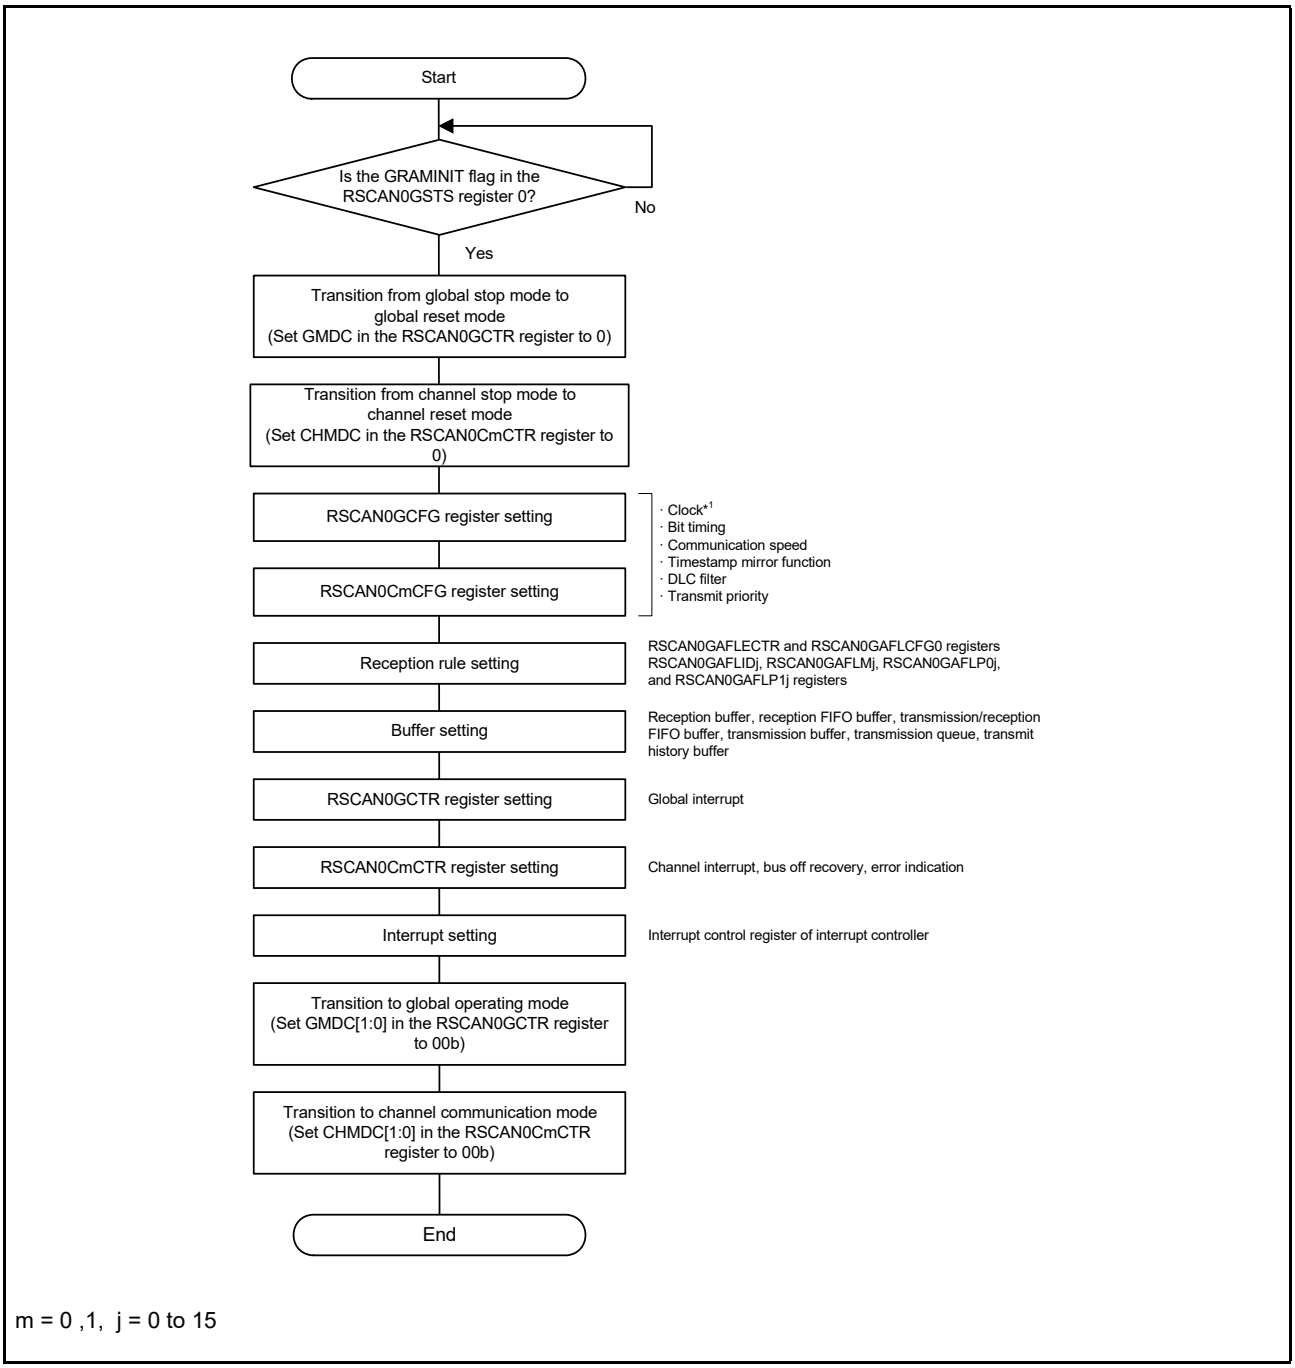

Figure 35.16 CAN Setting Procedure after the MCU is Reset

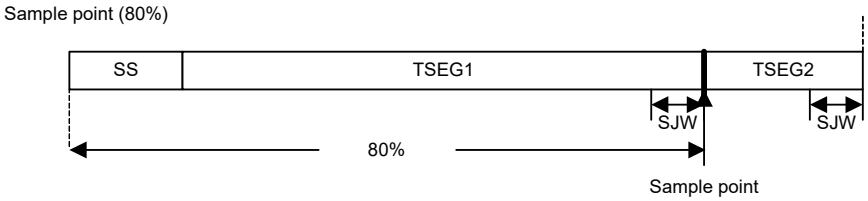
35.9.1.1 Clock Setting

Set the CAN clock (fCAN) as a clock source of the RSCAN module. Select CANCLKA (24 MHz) or CANCLKB (25 MHz) using the DCS bit in the RSCAN0GCFG register.

35.9.1.2 Bit Timing Setting

In the CAN protocol, one bit of a communication frame consists of three segments SS, TSEG1, and TSEG2, of which two segments TSEG1 and TSEG2 can be set by the RSCAN0CmCFG register for each channel. Sample point timing can be determined by setting these two segments. This timing can be adjusted in units of 1 Time Quantum (hereafter referred to as Tq). 1 Tq is equal to one CANmTq clock cycle. The CANmTq clock is obtained by selecting the clock source with the DCS bit in the RSCAN0GCFG register and selecting the clock division ratio with the BRP[9:0] bits in the RSCAN0CmCFG register.
Figure 35.17 shows the bit timing chart. Table 35.22 shows an example of bit timing setting.



SS = 1 Tq fixed
Set TSEG1 to a range of 4 Tq to 16 Tq
Set TSEG2 to a range of 2 Tq to 8 Tq
Set SJW to a range of 1 Tq to 4 Tq
Set SS + TSEG1 + TSEG2 to a range of 8 Tq to 25 Tq
TSEG1 > TSEG2 > SJW

- SS (synchronization segment):
  The SS is a segment that performs synchronization by monitoring the edge from recessive to dominant bits in the Interframe Space. Interframe Space consists of Intermission, Suspend Transmission, and Bus Idle. All nodes can start transmission during Bus Idle.
- TSEG1 (Time segment 1):
  TSEG1 is a segment that absorbs physical delay on the CAN network. The physical delay on the CAN network is twice the total of the delay on the CAN bus, the delay in the input comparator, and the delay in the output driver.
- TSEG2 (Time segment 2):
  TSEG2 is a segment that compensates phase error due to an error in frequency.
- SJW (Resynchronization jump width):
  The SJW is a length to extend or reduce the time segment to compensate for an error in phase due to phase error.

Figure 35.17 Bit Timing Chart

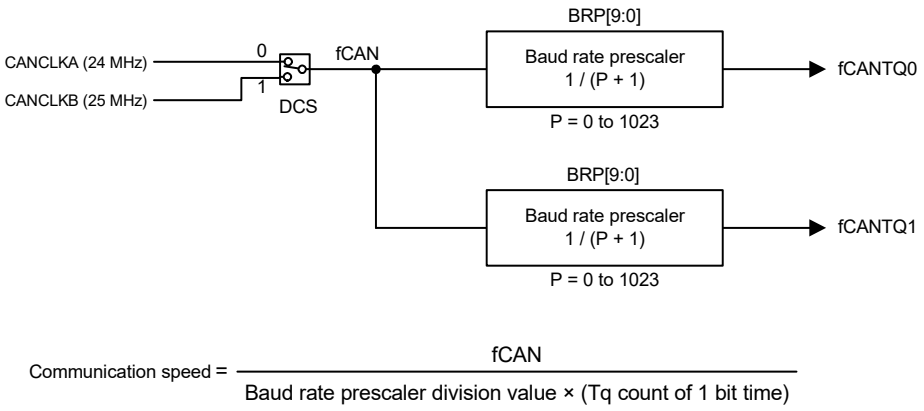
Table 35.22 Example of Bit Timing Setting

1 Bit	Set Value (Tq)				Sample Point (%) Note: See Figure 35.17.
	SS	TSEG1	TSEG2	SJW	
8 Tq	1	4	3	1	62.50
	1	5	2	1	75.00
10 Tq	1	6	3	1	70.00
	1	7	2	1	80.00
12 Tq	1	8	3	1	75.00
	1	9	2	1	83.33
16 Tq	1	10	5	1	68.75
	1	11	4	1	75.00
20 Tq	1	12	7	1	65.00
	1	13	6	1	70.00
24 Tq	1	15	8	1	66.67
	1	16	7	1	70.83
25 Tq	1	16	8	1	68.00

35.9.1.3 Communication Speed Setting

Set the CAN communication speed for each channel using the fCAN, baud rate prescaler division value (BRP[9:0] bits in the RSCAN0CmCFG register), and Tq count per bit time.

Figure 35.18 shows the CAN clock control block diagram, and Table 35.23 shows an example of the communication speed setting.



m = 0, 1
DCS: Bit in the RSCAN0GCFG register
BRP[9:0]: Bits in the RSCAN0CmCFG register
fCAN: CAN clock

Figure 35.18 CAN Clock Control Block Diagram

Table 35.23 Example of Communication Speed Setting

Communication Speed \ fCAN	25 MHz	24 MHz
1 Mbps	25 Tq (1)	8 Tq (3) 12 Tq (2) 24 Tq (1)
500 Kbps	25 Tq (2) 10 Tq (5)	8 Tq (6) 12 Tq (4) 24 Tq (2)
250 Kbps	25 Tq (4) 10 Tq (10)	8 Tq (12) 12 Tq (8) 24 Tq (4)
125 Kbps	25 Tq (8) 10 Tq (20)	8 Tq (24) 12 Tq (16) 24 Tq (8)

Note: Values in ( ) are baud rate prescaler division values.

35.9.1.4 Reception Rule Setting

Reception rules can be set using reception rule-related registers.
Up to 16 reception rules can be registered per page. Specify pages 0 to 7 by the AFLPN[4:0] bits in the RSCAN0GAFLECTR register. Enable or disable writing to the reception rule table using the AFLDAE bit.
Figure 35.19 shows the reception rule setting procedure.

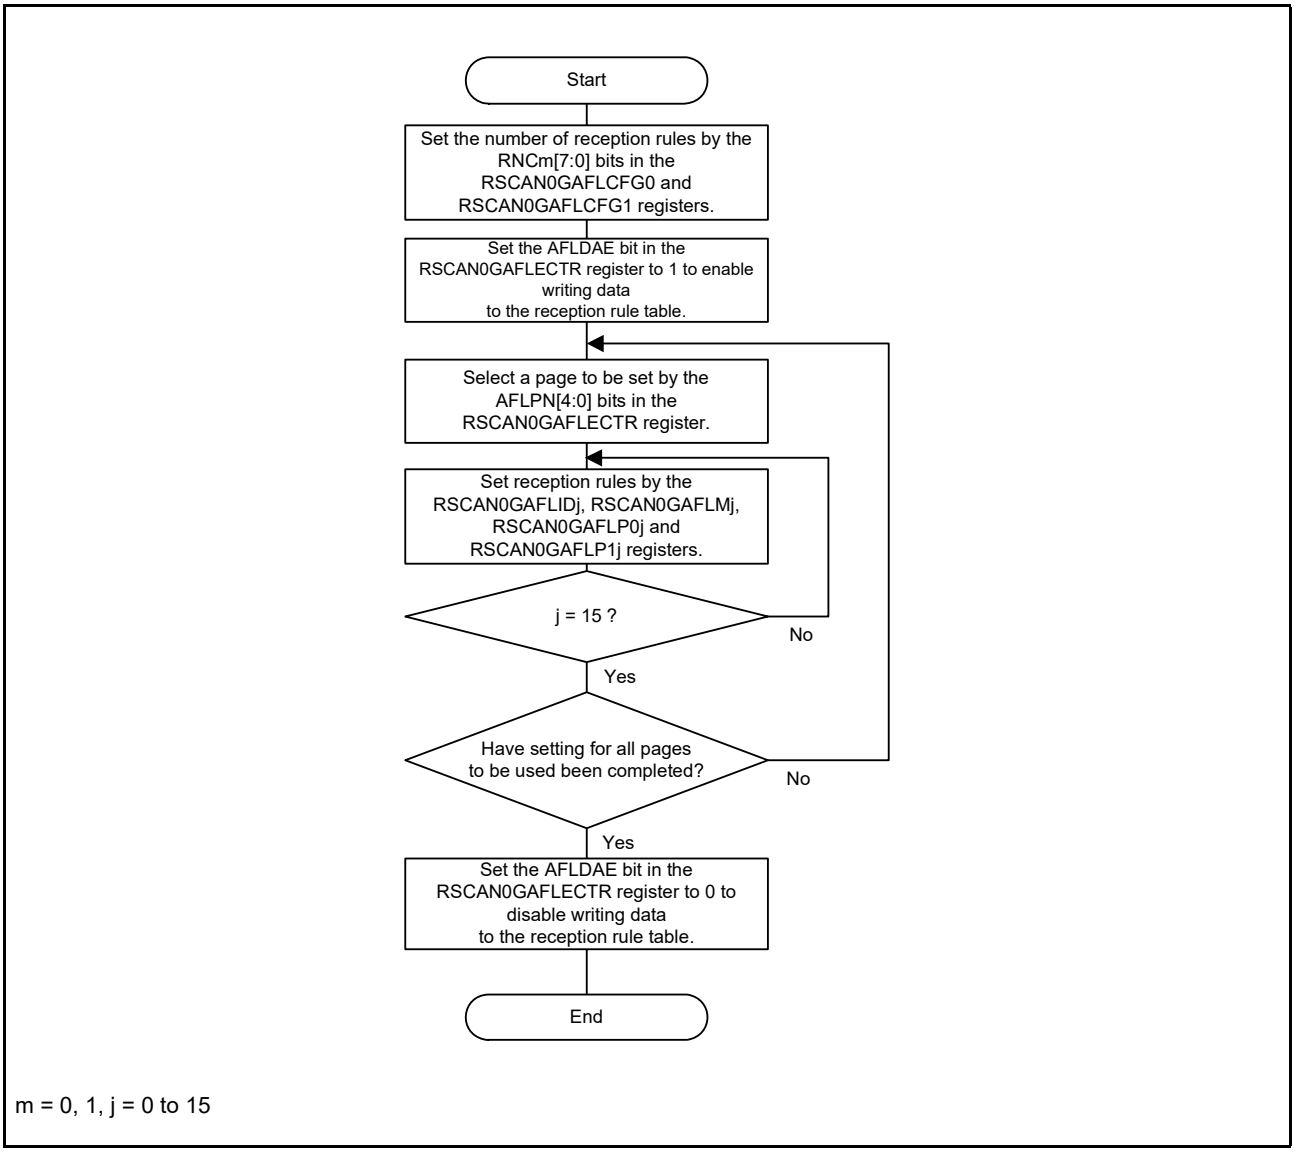


Figure 35.19 Reception Rule Setting Procedure

35.9.1.5 Buffer Setting

Set sizes and interrupt sources of buffers. For transmission/reception FIFO buffers that are set to transmission mode, set transmission buffers to be linked.

Figure 35.20 shows the buffer configuration. Figure 35.21 shows the buffer setting procedure.

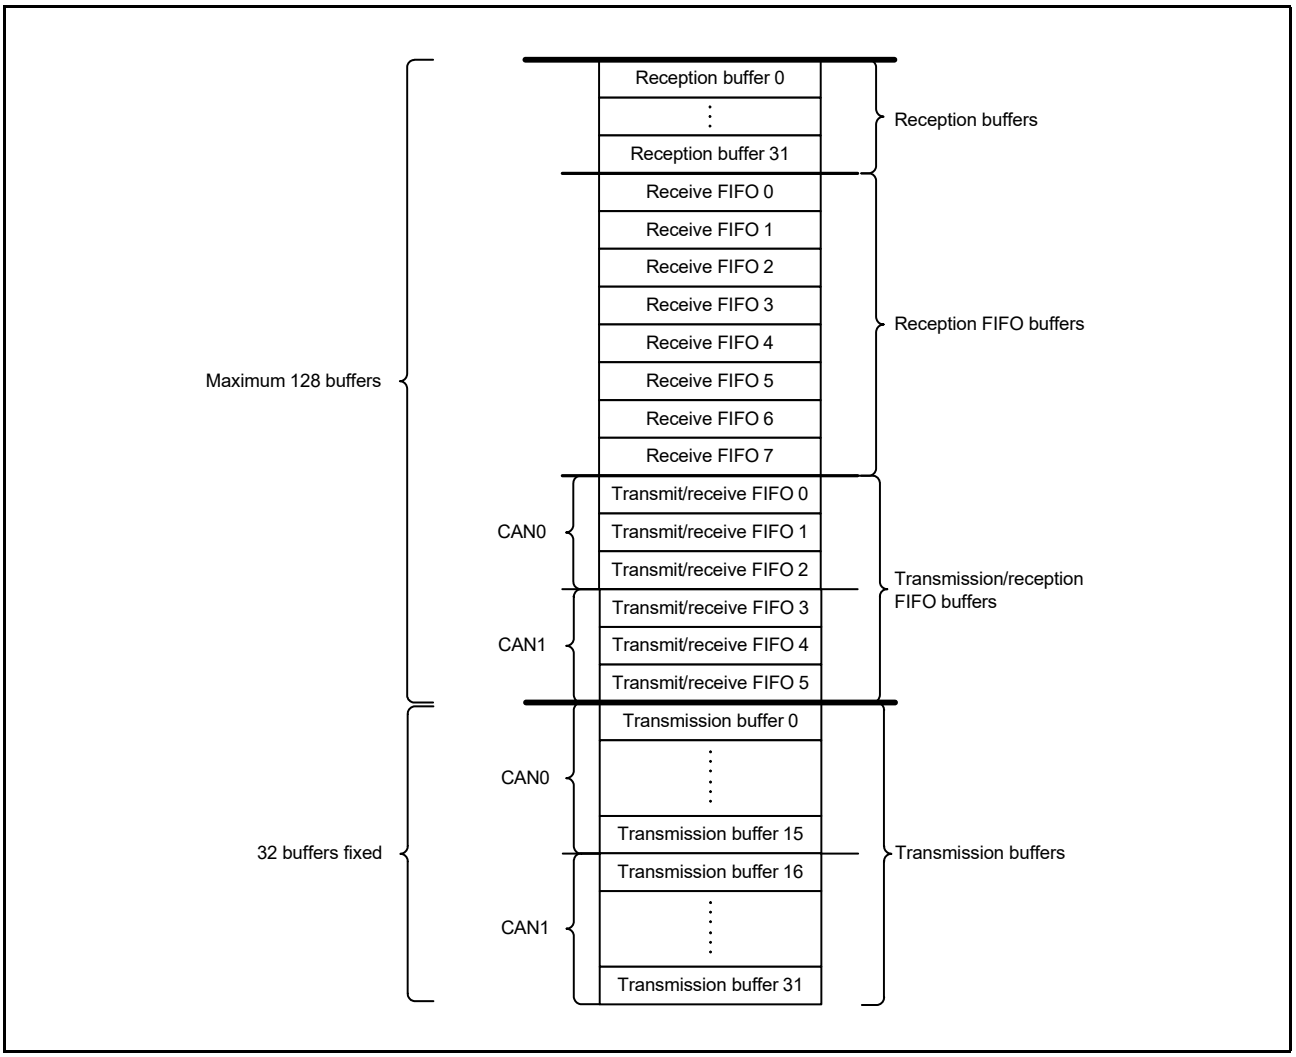

Figure 35.20 Buffer Configuration

Note: Reception buffers, reception FIFO buffers, transmission/reception FIFO buffers, and transmission buffers are located in succession.

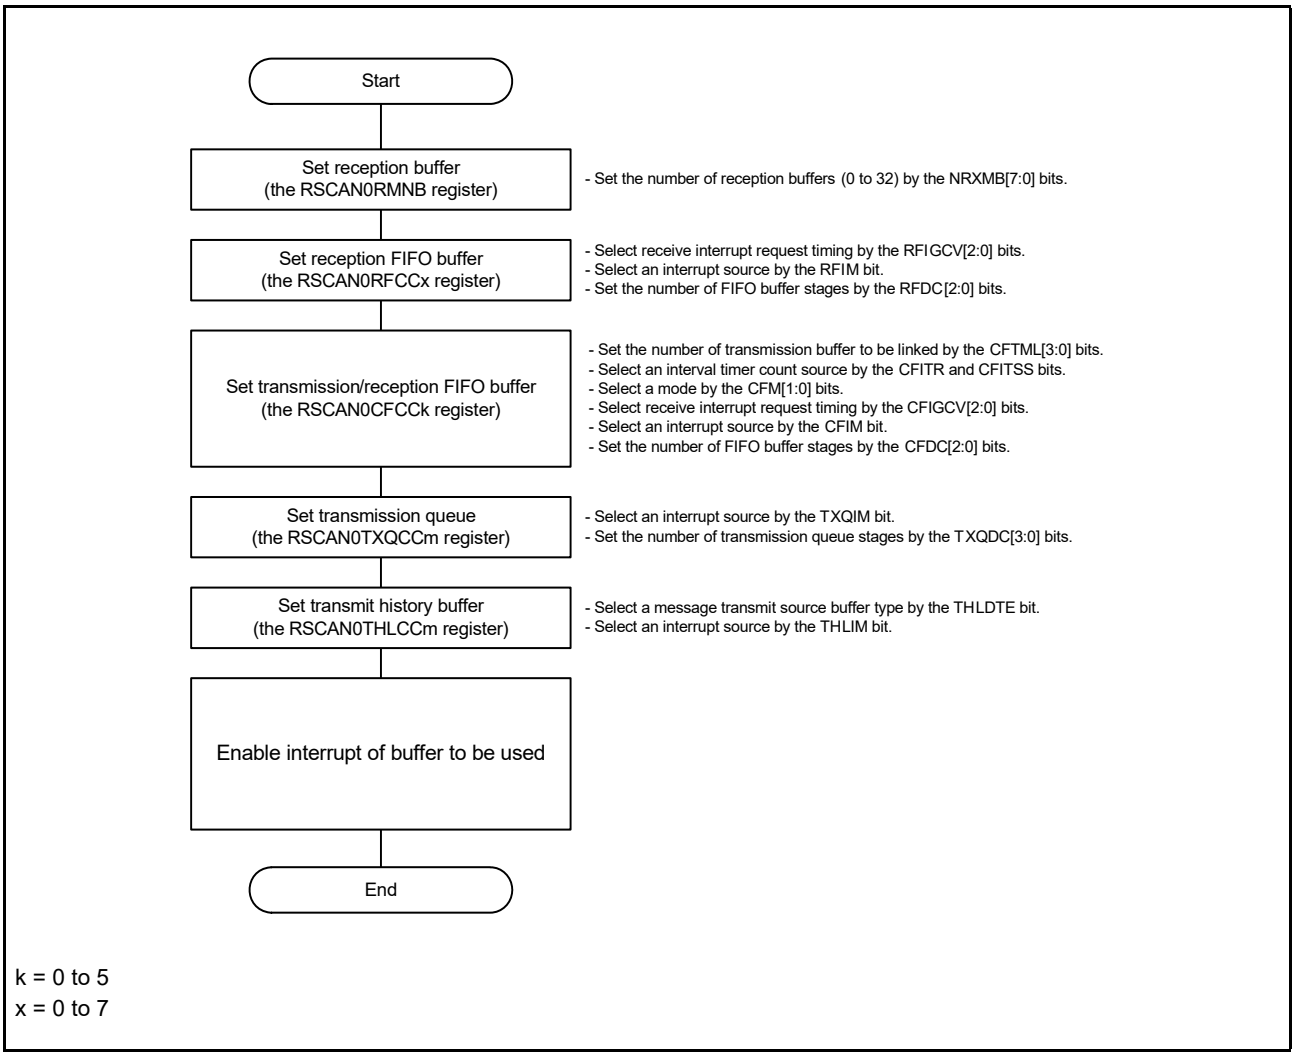

Figure 35.21 Buffer Setting Procedure

35.9.2 Reception Procedure

35.9.2.1 Reception Buffer Reading Procedure

When the processing to store received messages in a reception buffer starts, the RMNSq flag in the RSCAN0RMND0 register (q = 0 to 31) is set to 1 (reception buffer q contains a new message). Messages can be read from the RSCAN0RMIDq, RSCAN0RMPTRq, RSCAN0RMDF0q, and RSCAN0RMDF1q registers. If the next message has been received before the current message is read from the reception buffer, the message is overwritten. Figure 35.22 shows the reception buffer reading procedure.

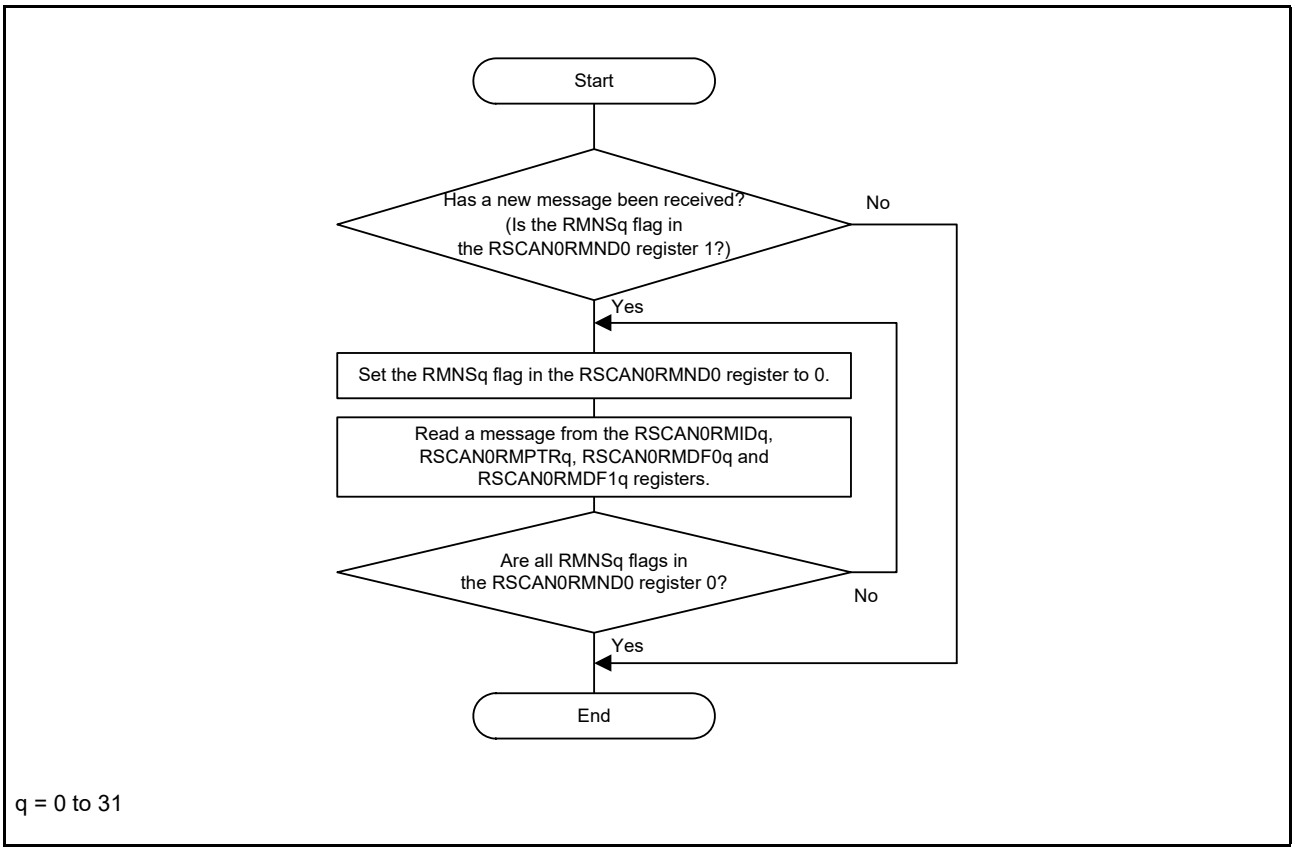

Figure 35.22 Reception Buffer Reading Procedure

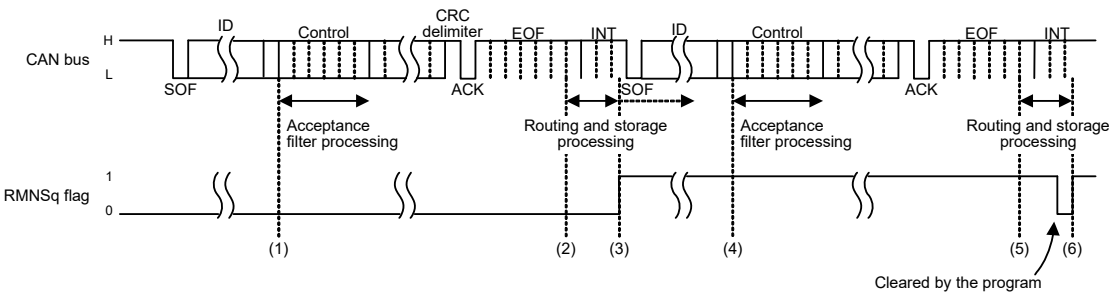

q = 0 to 31
RMNSq: Flag in the RSCAN0RMND0 register

Figure 35.23 Reception Buffer Reception Timing Chart

(1) When the ID field in a message has been received, the acceptance filter processing starts.

(2) When the message matches the reception rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing, the processing to store the message in the specified reception buffer starts.
When the message storage processing starts, the RMNSq flag in the corresponding RSCAN0RMND0 register is set to 1 (the reception buffer contains a new message). If other channels are performing filter processing or transmit priority determination processing, the routing processing and the storage processing may be delayed.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) When the message matches the reception rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(6) When the corresponding RMNSq flag is cleared to 0 (the reception buffer contains no new message), this flag is set to 1 again when the message storage processing starts. Even if the RMNSq flag remains 1, a new message is overwritten to the reception buffer. The RMNSq flag should not be cleared to 0 during storage of messages.

35.9.2.2 FIFO Buffer Reading Procedure

When received messages have been stored in one or more reception FIFO buffers or a transmission/reception FIFO buffer that is set to reception mode or gateway mode, the corresponding message count display counter (RFMC[7:0] bits in the RSCAN0RFSTSx register (x = 0 to 7) or CFMC[7:0] bits in the RSCAN0CFSTSk register (k = 0 to 5)) is incremented. At this time, when the RFIE bit (receive FIFO interrupt is enabled) in the RSCAN0RFCCx register or the CFRXIE bit (transmit/receive FIFO receive interrupt is enabled) in the RSCAN0CFCCk register is set to 1, an interrupt request is generated. Received messages can be read from the RSCAN0RFIDx, RSCAN0RFPTRx, RSCAN0RFDF0x, and RSCAN0RFDF1x registers for reception FIFO buffers, or from the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers for transmission/reception FIFO buffers. Messages in FIFO buffers can be read sequentially on a first-in, first-out basis.

When the message count display counter value matches the FIFO buffer depth (a value set by the RFDC[2:0] bits in the RSCAN0RFCCx register or the CFDC[2:0] bits in the RSCAN0CFCCk register), the RFFLL or CFFLL flag is set to 1 (the reception FIFO buffer is full).

When all messages have been read out of the FIFO buffer, the RFEMP flag in the RSCAN0RFSTSx register or the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the reception FIFO buffer contains no unread message (buffer empty)).

If the RFE bit or the CFE bit is cleared to 0 (no reception FIFO buffer is used) with the interrupt request flag (RFIF flag in the RSCAN0RFSTSx register or CFRXIF flag in the RSCAN0CFSTSk register) set to 1 (a receive FIFO interrupt request is present), the interrupt request flag is not automatically cleared to 0. The program must clear the interrupt request flag to 0.

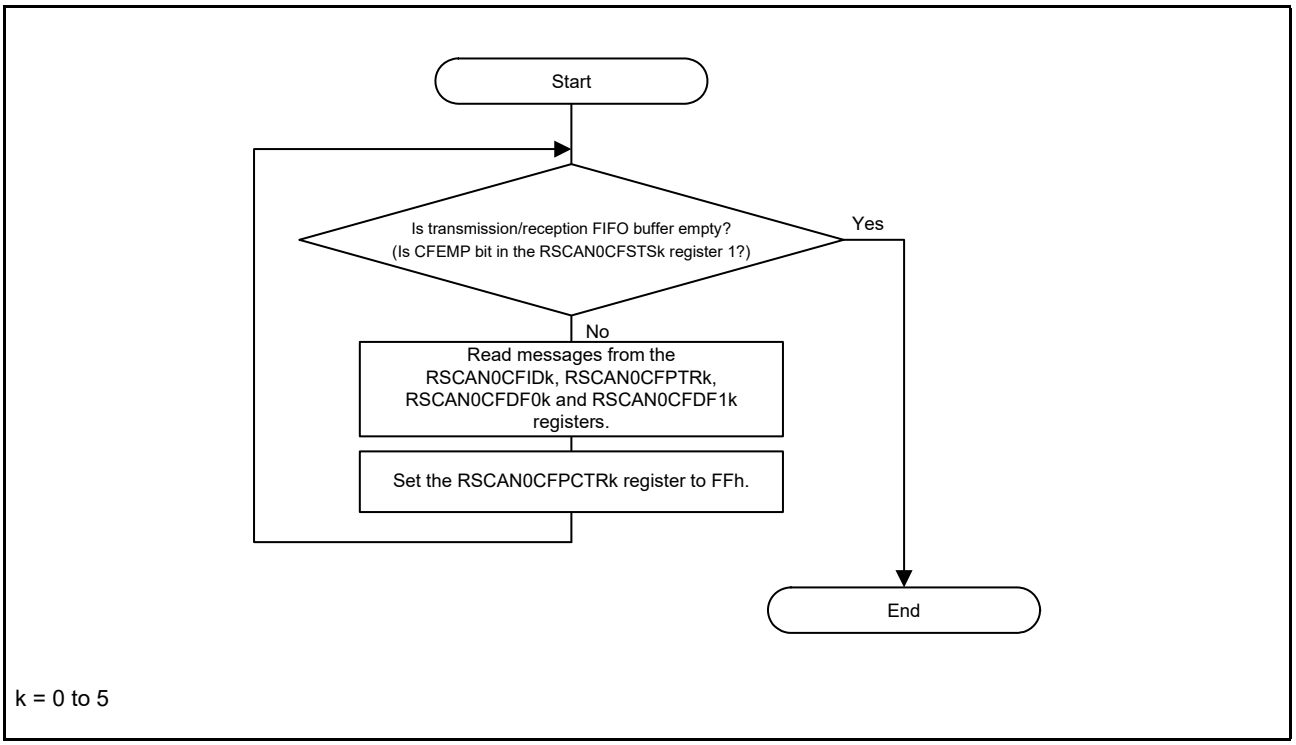

Figure 35.24 Transmission/Reception FIFO Buffer Reading Procedure

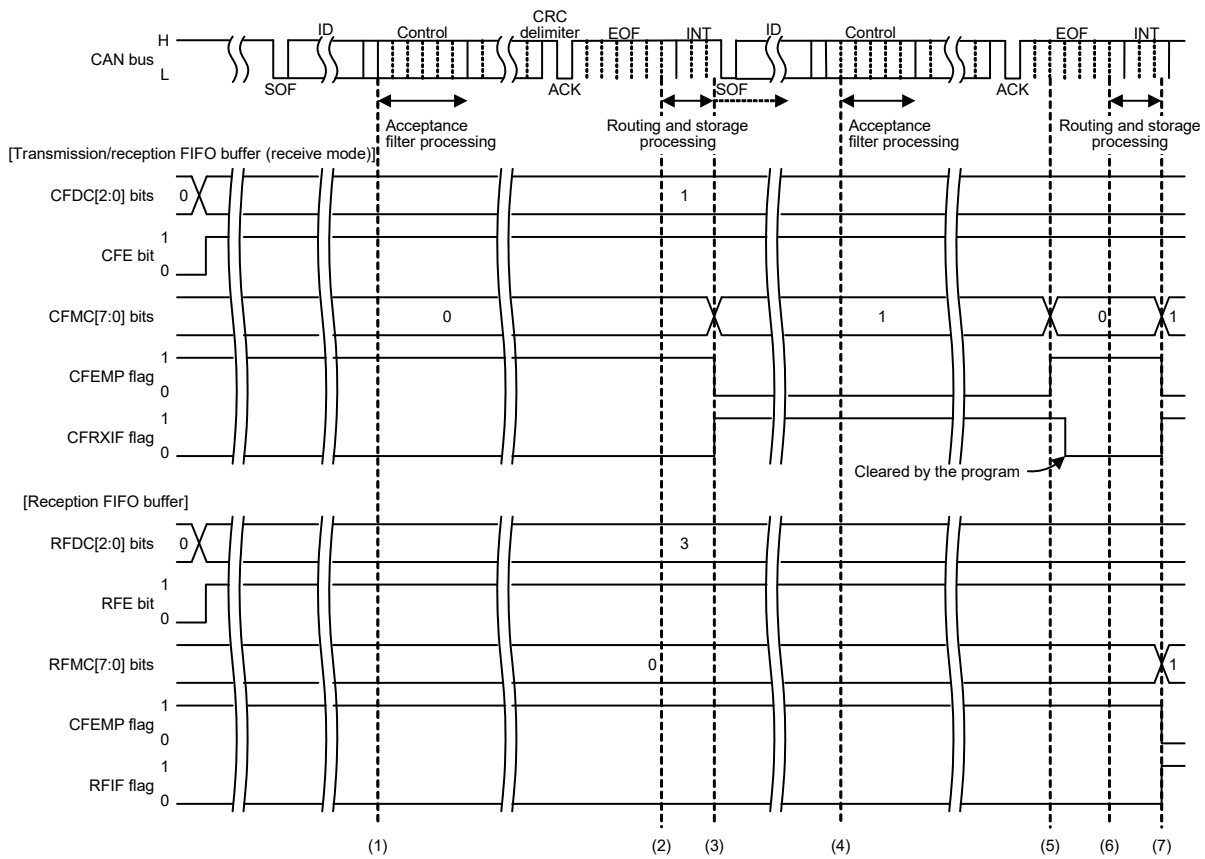

k = 0 to 5, x = 0 to 7
CFDC[2:0], CFE: Bits in the RSCAN0CFCCk register
CFMC[7:0], CFEMP, CFRXIF: Flags in the RSCAN0CFSTSk register
RFDC[2:0], RFE: Bits in the RSCAN0RFCCx register
RFMC[7:0], CFEMP, RFIF: Flags in the RSCAN0RFSTSx register

Figure 35.25 FIFO Buffer Reception Timing Chart

(1) When the ID field in a message has been received, the acceptance filter processing starts.

(2) When the message matches the reception rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(3) When the message has passed through the DLC filter processing and the CFE bit in the RSCAN0CFCCk register is 1 (transmission/reception FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCk register is 001b or more, the message is stored in the transmission/reception FIFO buffer that is set to reception mode. The CFMC[7:0] value in the RSCAN0CFSTSk register is incremented and becomes 01h. When the CFIM bit in the RSCAN0CFCCk register is set to 1 (a FIFO receive interrupt request is generated each time a message has been received), the CFRXIF flag in the RSCAN0CFSTSk register is set to 1 (a transmit/receive FIFO receive interrupt request is present). The CFRXIF flag can be reset to 0 by the program.

(4) When the ID field of the next message has been received, the acceptance filter processing starts.

(5) Read received messages from the RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers and write FFh to the RSCAN0CFPCTRk register. This causes the CFMC[7:0] bits in the RSCAN0CFSTSk register to be decremented. When CFMC[7:0] becomes 00h, the CFEMP flag in the RSCAN0CFSTSk register becomes 1 (the transmission/reception FIFO buffer contains no message (buffer empty)).

(6) When the message matches the reception rule of the corresponding channel and the message has been successfully received, the routing processing to transfer the message to the specified buffer starts. When the DCE bit in the RSCAN0GCFG register is set to 1 (DLC check is enabled), the DLC filter processing starts at this time.

(7) The message is stored in the transmission/reception FIFO buffer set in reception mode when the message has passed through the DLC filter process if the CFE bit is set to 1 (transmission/reception FIFO buffers are used), and the CFDC[2:0] bits are set to 001b or more. The CFMC[7:0] bit value is incremented by 1 to be 01h. When the CFIM bit is set to 1 (an interrupt occurs each time a message has been received), the CFRXIF flag is set to 1 (a transmit/receive FIFO receive interrupt request is present).
The message is stored in the reception FIFO buffer if the RFE bit in the RSCAN0RFCCx register is set to 1 (reception FIFO buffers are used), and the RFDC[2:0] bits in the RSCAN0RFCCx register are set to 001b or more. The RFMC[7:0] bits in the RSCAN0RFSTSx register are set to 01h by being incremented by 1. When the RFIM bit in the RSCAN0RFCCx register is set to 1 (an interrupt occurs each time a message has been received), the RFIF flag in the RSCAN0RFSTSx register is set to 1 (a receive FIFO interrupt request is present).

35.9.3 Transmission Procedure

35.9.3.1 Procedure for Transmission from Transmission Buffers

Figure 35.26 shows the procedure for transmission from transmission buffers.
Figure 35.27 shows a timing chart where messages are transmitted from two transmission buffers in the same channel and transmission has been successfully completed. Figure 35.28 shows a timing chart where messages are transmitted from two transmission buffers in the same channel and transmission abort has been completed.

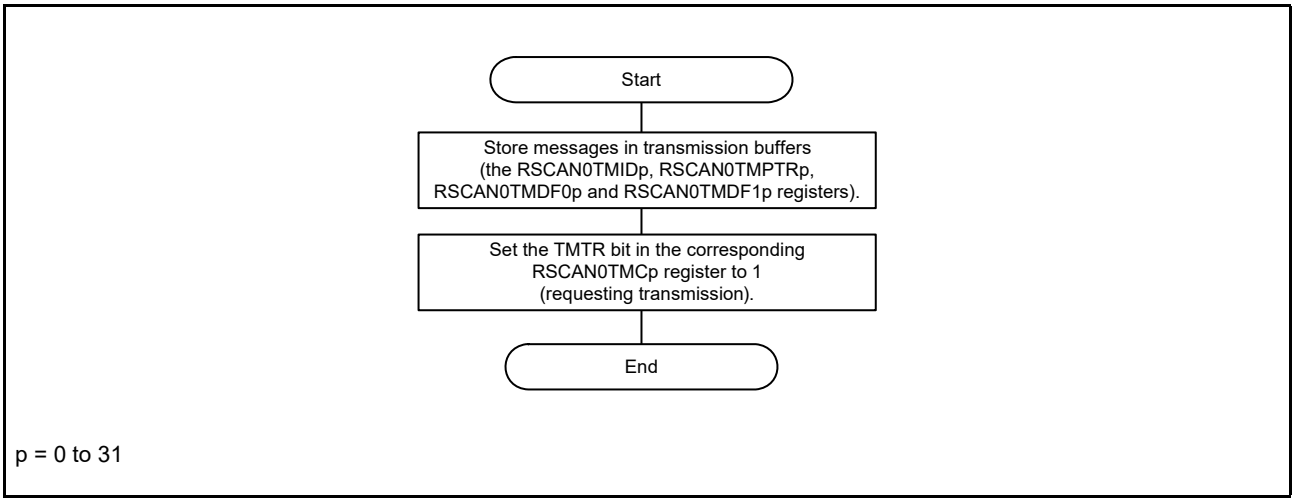

Figure 35.26 Procedure for Transmission from Transmission Buffers

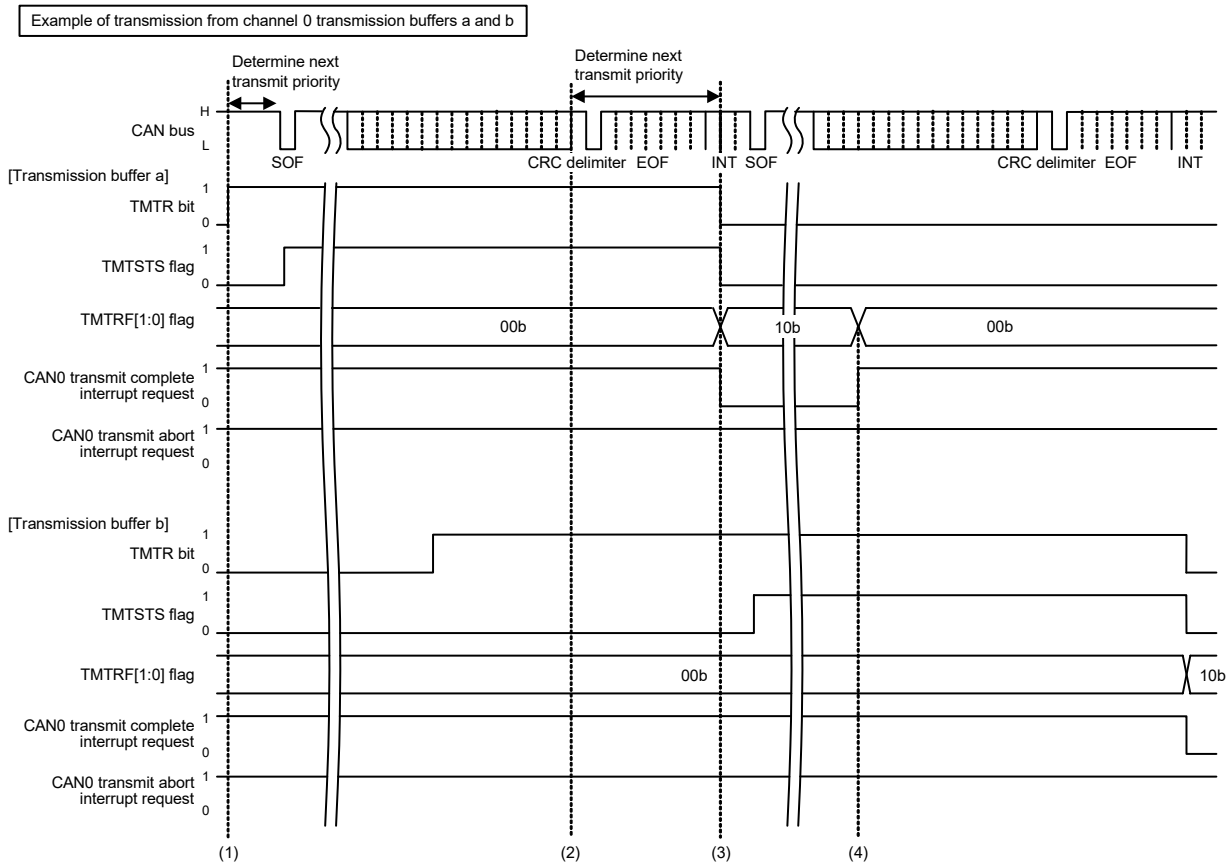


a = 0 to 31, b = 0 to 31
TMTR: Bit in the RSCAN0TMCp register
TMTSTS, TMTRF[1:0]: Flags in the RSCAN0TMSTSp registers

Figure 35.27 Transmission Buffer Transmission Timing Chart (Transmission Completed Successfully)

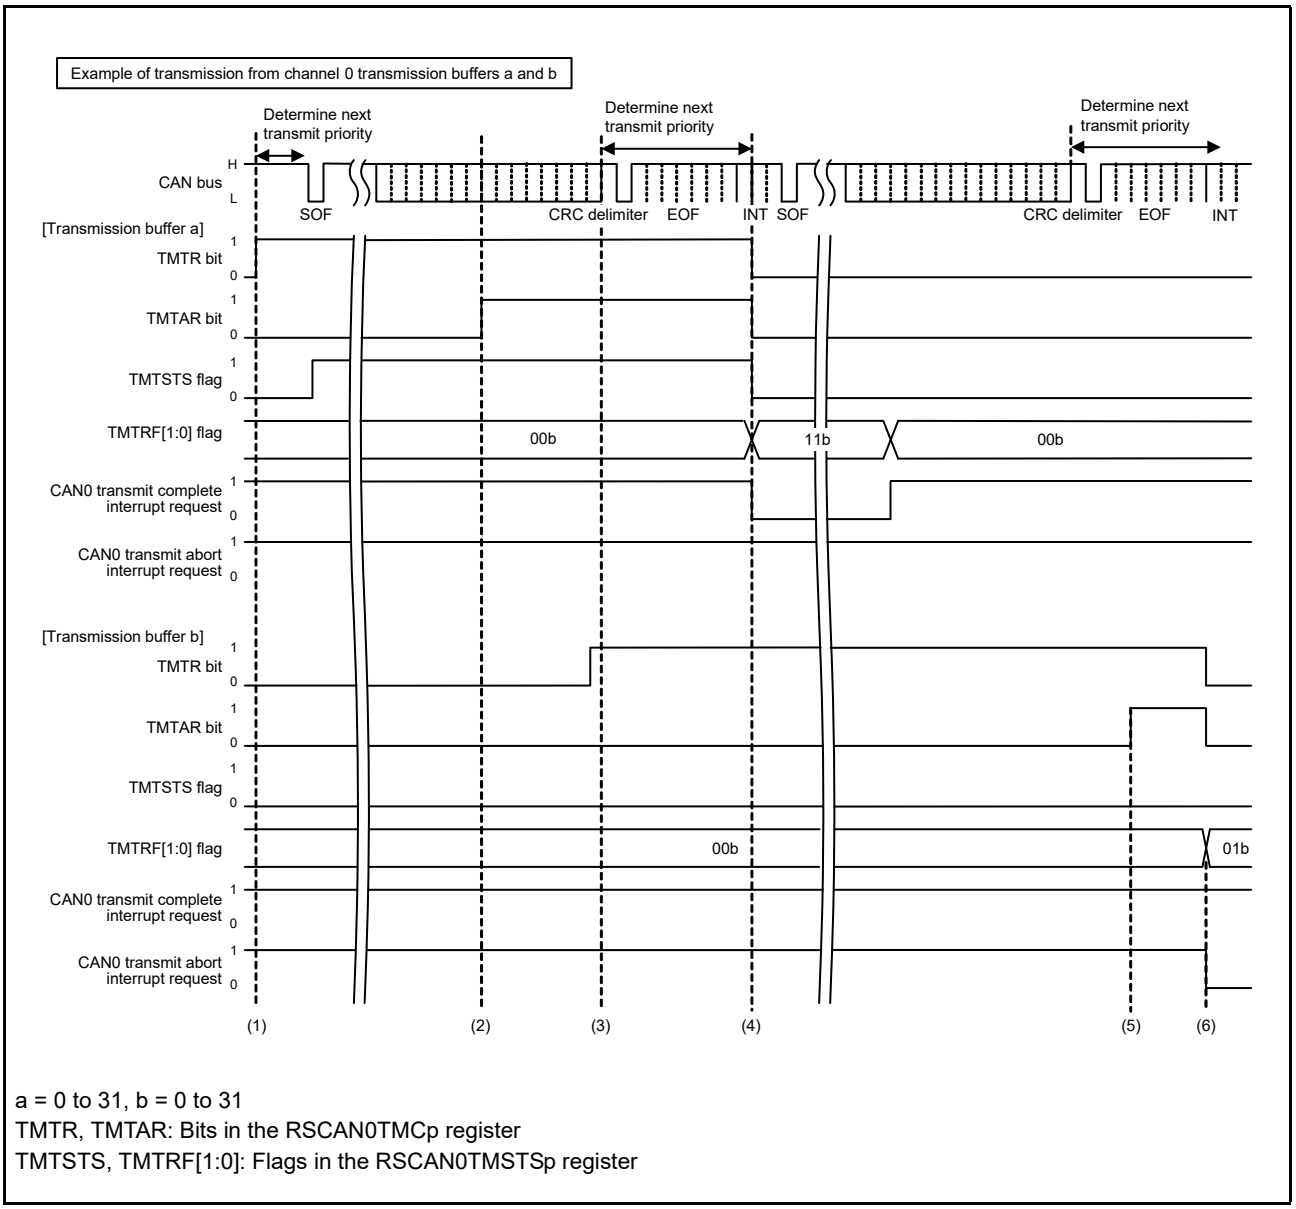
(1) When the TMTR bit in the RSCAN0TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmission buffer. If transmission buffer a is determined to be the highest-priority transmission buffer, the TMTSTS flag in the corresponding RSCAN0TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When a transmission request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(3) When transmission completes successfully, the TMTRF[1:0] flag in the RSCAN0TMSTSa register is set to 10b (transmission has been completed (without transmission abort request)) and the TMTSTS flag and the TMTR bit in the RSCAN0TMCa register are cleared to 0. When the TMIEa bit in the RSCAN0TMIEC0 register is 1 (transmission buffer interrupt is enabled), a CAN0 transmission complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00b (transmission is in progress or no transmission request is present).

(4) Before starting the next transmission, set the TMTRF[1:0] flag to 00b. Write the next message to the transmission buffer, and then set the TMTR bit to 1 (transmission is requested). The TMTR bit can be set to 1 only when the TMTRF[1:0] flag value is 00b.

If an arbitration-lost has occurred after transmission is started, the TMTSTS flag is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to search the highest-priority transmission buffer. If an error has occurred during transmission or after arbitration loss, the priority determination processing is reexecuted during transmission of an error frame.



a = 0 to 31, b = 0 to 31
TMTR, TMTAR: Bits in the RSCAN0TMCp register
TMTSTS, TMTRF[1:0]: Flags in the RSCAN0TMSTSp register

Figure 35.28 Transmission Buffer Transmission Timing Chart (Transmission Abort Completed)

(1) When the TMTR bit in the RSCAN0TMCa register is set to 1 while the CAN bus is idle, the transmit priority determination processing starts to determine the highest-priority transmission buffer. If transmission buffer a is determined to be the highest-priority transmission buffer, the TMTSTS flag in the corresponding RSCAN0TMSTSa register is set to 1 (transmission is in progress) and the CAN channel starts transmitting data.

(2) When it is determined that the transmission buffer is used for the next transmission or transmission is in progress, message transmission is not aborted unless an error or arbitration loss occurs even if the TMTAR bit is set to 1 (transmission abort is requested).

(3) The priority determination starts with the CRC delimiter for the next transmission. In this timing chart, buffer b is not selected as the next transmission buffer. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(4) When transmission completes successfully, the TMTRF[1:0] flag in the RSCAN0TMSTSa register is set to 11b (transmission has been completed (with transmission abort request)) and the TMTSTS flag and the TMTR bit in the RSCAN0TMCa register are cleared to 0. When the TMIEa value in the RSCAN0TMIEC0 register is 1 (transmission buffer interrupt is enabled), a CAN0 transmission complete interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00b (transmission is in progress or no transmission request is present).

(5) While another CAN node is transmitting data on the CAN bus (TMTSTS flag = 0), if the TMTAR bit is set to 1 while the corresponding channel is determining transmit priority, the TMTR bit cannot be cleared to 0.

(6) After the internal processing time has passed, the transmission is terminated and the TMTRF[1:0] flag is set to 01b. When the transmission buffer is not transmitting data and is not selected as the next transmission buffer and priority determination is not being made, an abort request is immediately accepted and the TMTRF[1:0] flag is set to 01b. At this time, the TMTR and TMTAR bits are cleared to 0. When transmission abort is completed with the TAIE bit in the RSCAN0CmCTR register set to 1 (transmission abort interrupt is enabled), an interrupt request is generated. To clear the interrupt request, set the TMTRF[1:0] flag to 00b.

If an arbitration loss has occurred after the CAN channel started transmission, the TMTSTS bit is cleared to 0. The transmit priority determination is reexecuted at the beginning of the CRC delimiter to find the highest-priority transmission buffer. If an error has occurred during transmission or after arbitration loss, the priority determination processing is reexecuted during transmission of an error frame.

35.9.3.2 Procedure for Transmission from Transmission/Reception FIFO Buffer

Figure 35.29 shows the procedure for transmission from transmission/reception FIFO buffers.
Figure 35.30 shows a timing chart where messages are transmitted from two transmission/reception FIFO buffers in the same channel and transmission has been successfully completed. Figure 35.31 shows a timing chart where messages are transmitted from two transmission/reception FIFO buffers in the same channel and transmission abort has been completed.

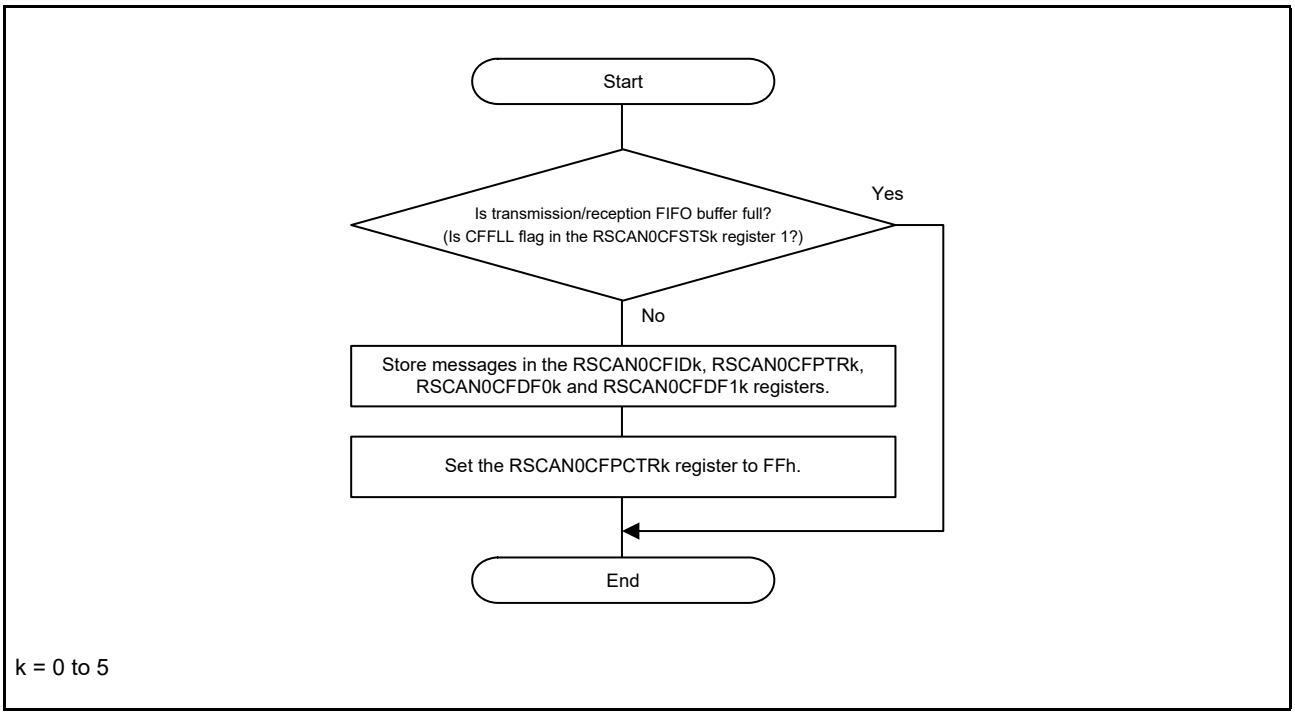


Figure 35.29 Procedure for Transmission from Transmission/Reception FIFO Buffers

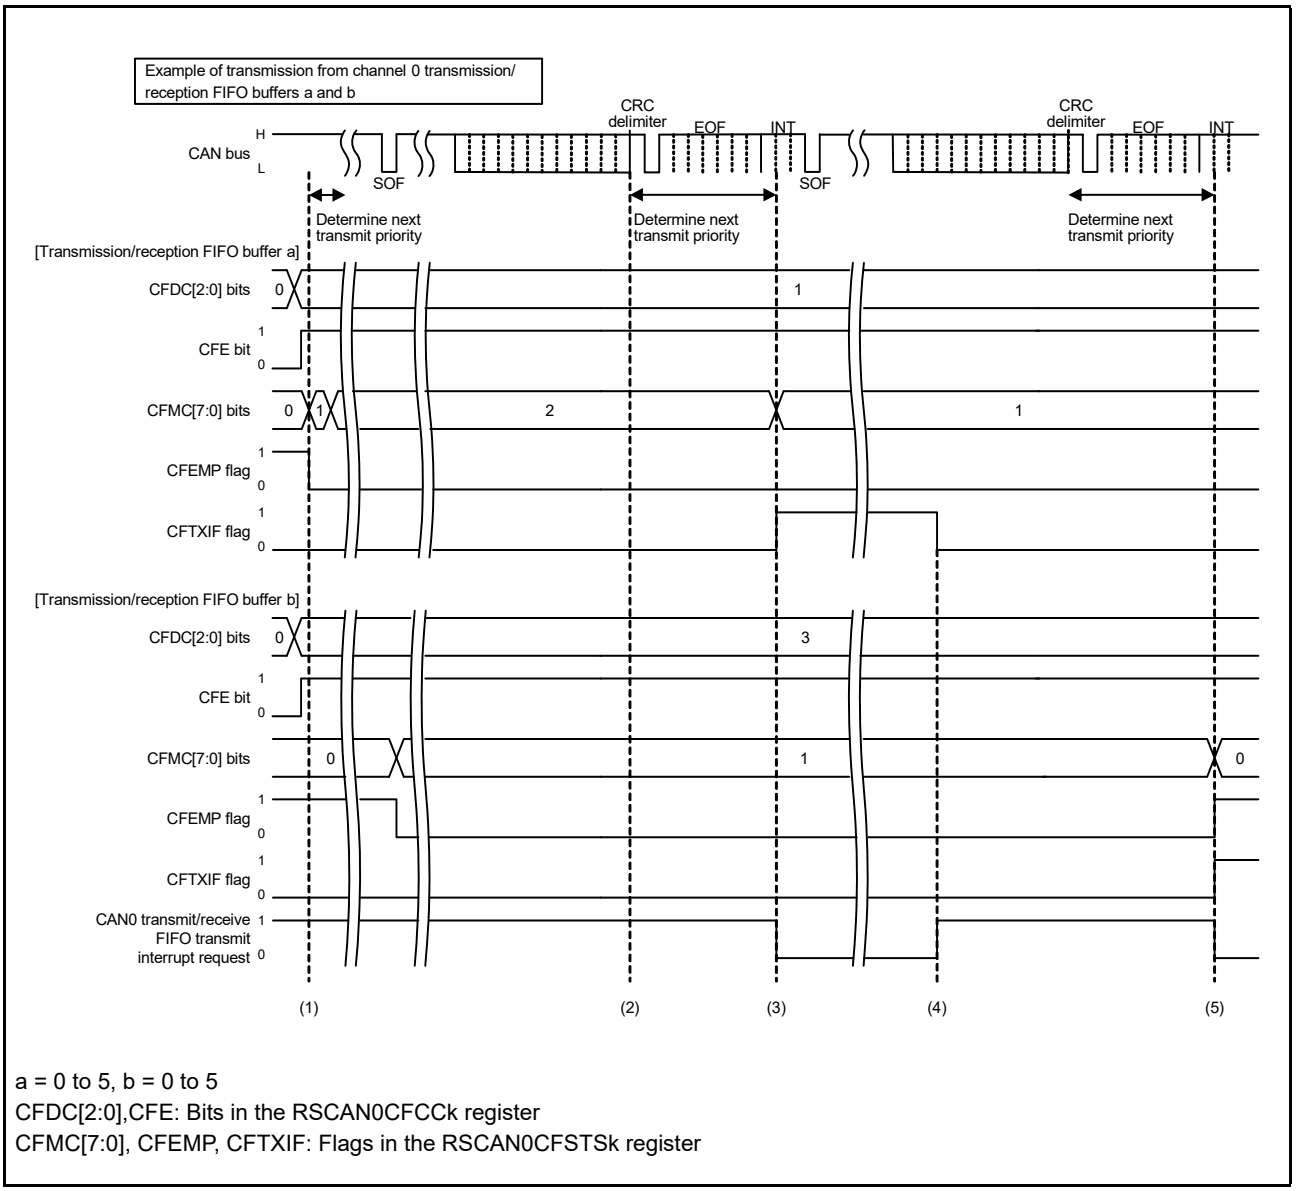

Figure 35.30 Transmission/Reception FIFO Buffer Transmission Timing Chart (Transmission Completed Successfully)

(1) While the CAN bus is idle, when the CFE bit in the RSCA0CFCCa register is 1 (transmission/reception FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCa register is 001b (4 messages) or more and the CFMC[7:0] value in the RSCAN0CFSTSa register is 01h or more, the priority determination processing starts to determine the highest-priority message for transmission. When the highest-priority message for transmission has been determined, transmission of the message starts. In this figure, the message is transmitted from transmission/ reception FIFO buffer a of channel 0.

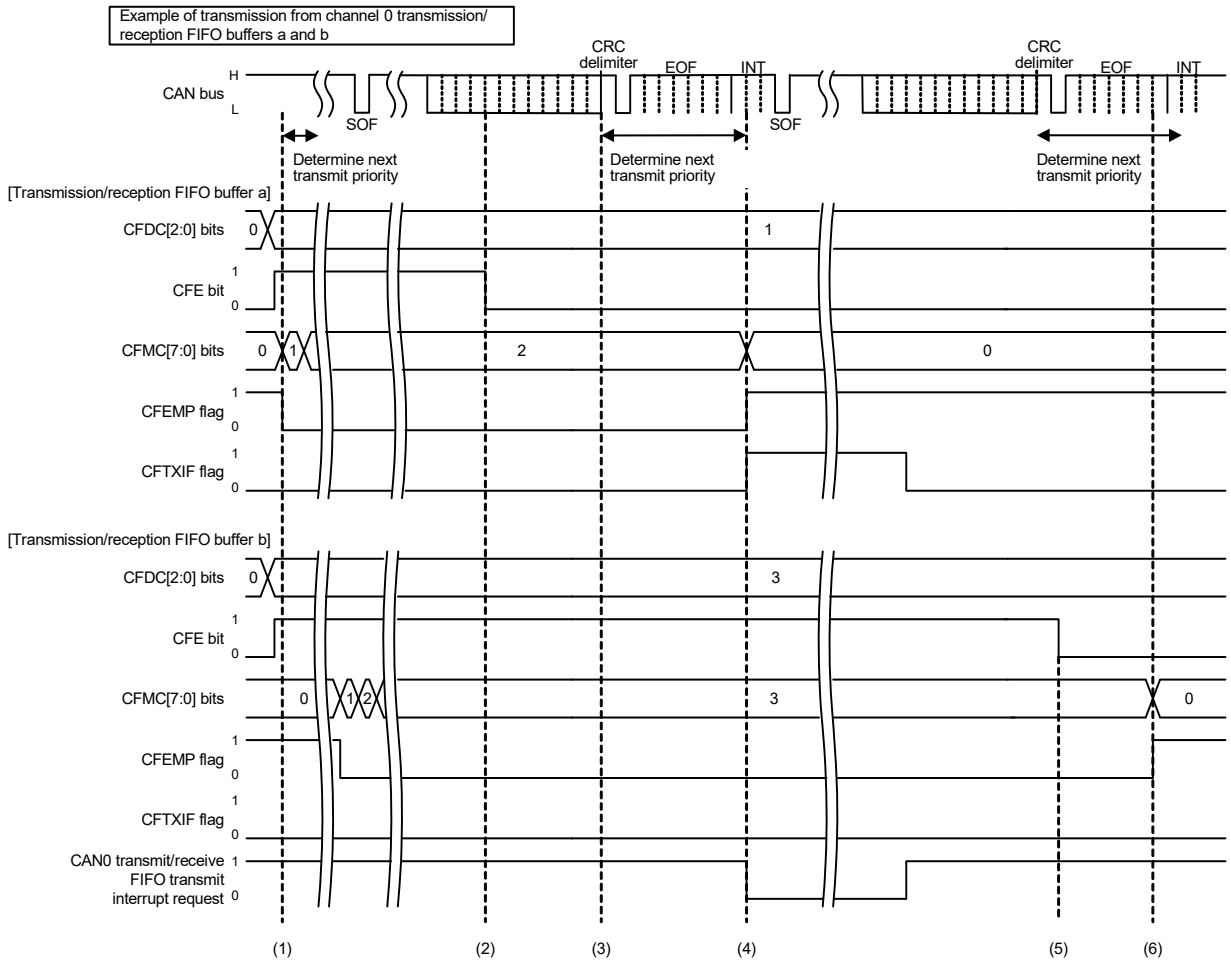
(2) When a transmission request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(3) When transmission completes successfully, the CFMC[7:0] value in the RSCAN0CFSTSa register is decremented. Setting the CFIM bit in the RSCAN0CFCCa register to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCAN0CFSTSk register to 1 (a transmit/receive FIFO transmit interrupt request is present).

(4) The program can clear the CFTXIF flag.

(5) Message transmission from transmission/reception FIFO buffer b of channel 0 has been completed and the CFMC[7:0] value in the RSCAN0CFSTSb register is decremented. The CFMC[7:0] bits are cleared to 00h and therefore the CFEMP flag in the RSCAN0CFSTSk register is set to 1 (the transmission/reception FIFO buffer contains no message (buffer empty)).

Transmission is continued until the CFEMP flag is set to 1. It is possible to continuously store messages for transmission in FIFO buffers until the CFFLL flag in the RSCAN0CFSTSa and RSCAN0CFSTSb register is set to 1 (the transmission/reception FIFO buffer is full).



a = 0 to 5, b = 0 to 5
CFDC[2:0], CFE: Bits in the RSCAN0CFCCk register
CFMC[7:0], CFEMP, CFTXIF: Flags in the RSCAN0CFSTSk register

Figure 35.31 Transmission/Reception FIFO Buffer Transmission Timing Chart (Transmission Abort Completed)

(1) While the CAN bus is idle, when the CFE bit in the RSCAN0CFCCa register (a = 0 to 5) is 1 (transmission/reception FIFO buffers are used) and the CFDC[2:0] value in the RSCAN0CFCCa register is 001b (4 messages) or more and the CFMC[7:0] value in the RSCAN0CFSTSa register is 01h or more, the priority determination processing starts to determine the highest-priority message for transmission. When the highest-priority message for transmission has been determined, transmission of the message starts. In this figure, the message is transmitted from transmission/reception FIFO buffer a of channel 0.

(2) When transmission is in progress or it is determined that the transmission/reception FIFO buffer is used for the next transmission, message transmission is not aborted unless an error or arbitration loss occurs even if the CFE bit is set to 0 (no transmission/reception FIFO buffer is used).

(3) When a transmission request from a buffer is present, the priority determination starts with the CRC delimiter for the next transmission. In this figure, transmission/reception FIFO buffer b is not selected as a buffer for the next transmission. The determination time may delay if the transmit priority determination processing is performed on another channel. However, the delay does not occur during transmission because the determination processing is completed by the third bit of the intermission.

(4) When transmission completes successfully, the CFMC[7:0] value is cleared to 00h. Setting the CFIM bit to 1 (a FIFO transmit interrupt request is generated each time a message has been transmitted) sets the CFTXIF flag in the RSCAN0CFSTSa register to 1 (a transmit/receive FIFO transmit interrupt request is present). The program can clear the CFTXIF flag.

(5) If another CAN node on the CAN bus is transmitting data (not from transmission/reception FIFO buffer b), transmission/reception FIFO buffers cannot be disabled immediately even if the CFE bit in the RSCAN0CFCCb register is cleared to 0 (no transmission/reception FIFO buffer is used) during transmit priority determination. (The CFEMP flag in the RSCAN0CFSTSb register is not set to 1 (the transmission/reception FIFO buffer contains no message (buffer empty)) immediately.)

(6) After the internal processing time has passed, transmission/reception FIFO buffers are disabled and the CFMC[7:0] bits in the RSCAN0CFSTSb register are cleared to 00h and the CFEMP flag is set to 1. When the transmission/reception FIFO buffer is not transmitting data and is not selected as the next transmission buffer and priority determination is not in progress, the transmission/reception FIFO buffer is immediately disabled. (The CFMC[7:0] bits are cleared to 00h and the CFEMP flag is set to 1.)

35.9.3.3 Procedure for Transmission from the Transmission Queue

Figure 35.32 shows the procedure for transmission from the transmission queue.

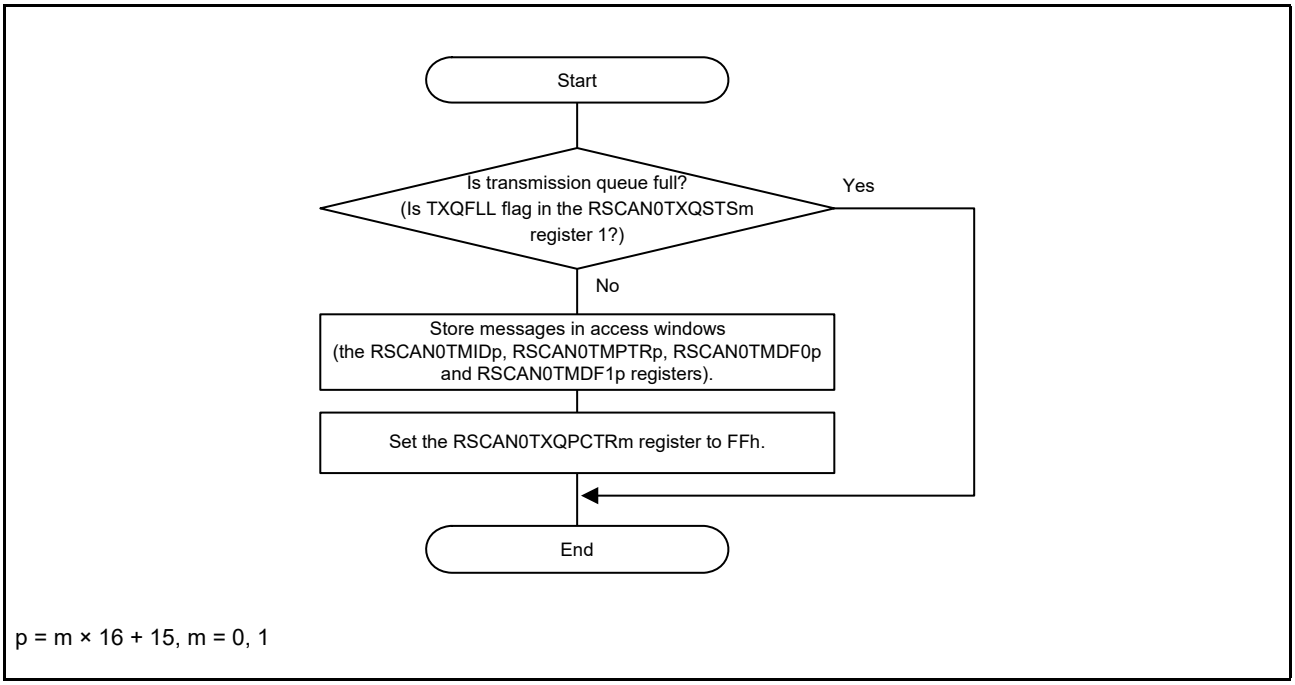


Figure 35.32 Procedure for Transmission from the Transmission Queue

35.9.3.4 Transmission History Buffer Reading Procedure

Transmission history data can be read from the RSCAN0THLACCm register. The next data can be accessed by writing FFh to the corresponding RSCAN0THLPCTRm register (m = 0, 1) after reading a set of data. Figure 35.33 shows the transmission history buffer reading procedure.

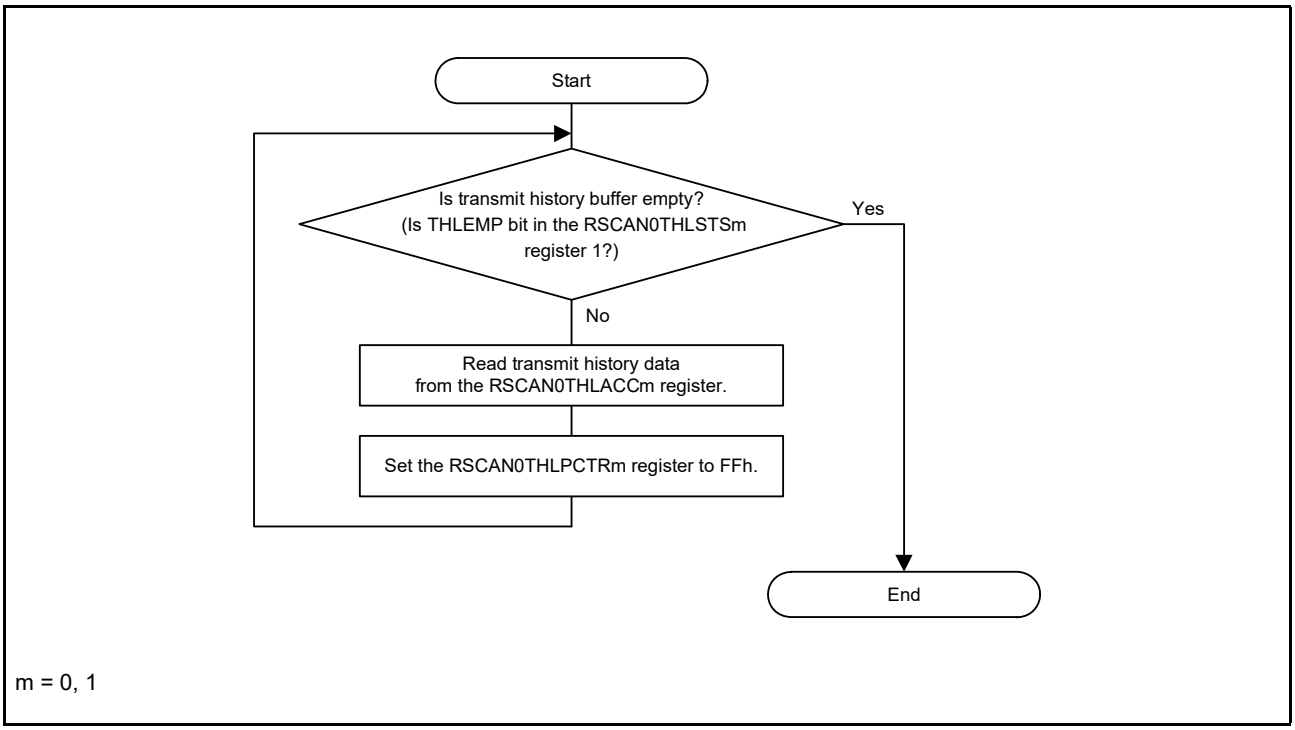

Figure 35.33 Transmission History Buffer Reading Procedure

35.9.4 Test Settings

35.9.4.1 Self-Test Mode Setting Procedure

Self-test mode allows communication test on a channel basis by enabling a CAN node to receive its own transmitted messages.

Figure 35.34 shows the self-test mode setting procedure.

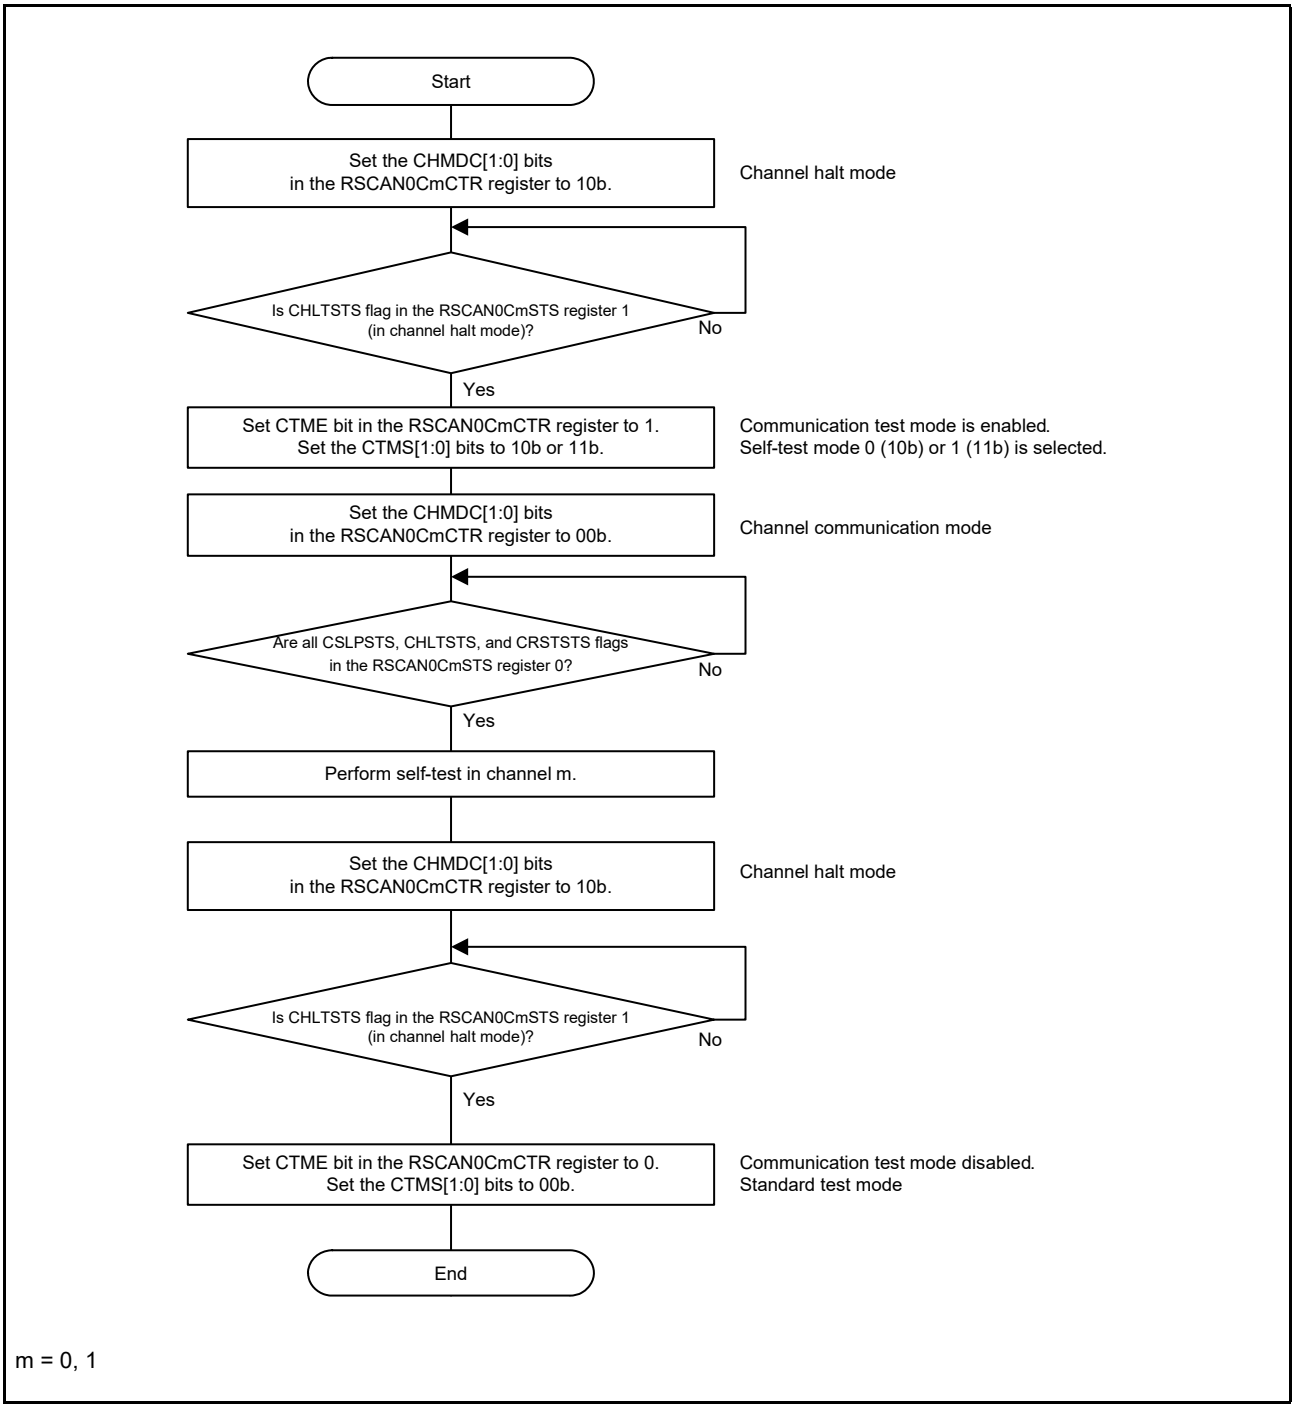

Figure 35.34 Self-Test Mode Setting Procedure

35.9.4.2 Procedure for Unlocking the Protection

Since the global test function in Table 35.24 is protected, write the protection unlock data 1 and unlock data 2 in succession to the LOCK[15:0] bits in the RSCAN0GLOCKK register, then set the target test bit to 1.

Table 35.24 Protection Unlock Data for Test Function

Test Function	Protection Unlock Data 1	Protection Unlock Data 2	Target Bit
RAM test	7575h	8A8Ah	RTME bit in the RSCAN0GTSTCTR register

If an incorrect value is written to the LOCK[15:0] bits, restart from writing the protection unlock data 1. Figure 35.35 shows the procedure for unlocking the protection.

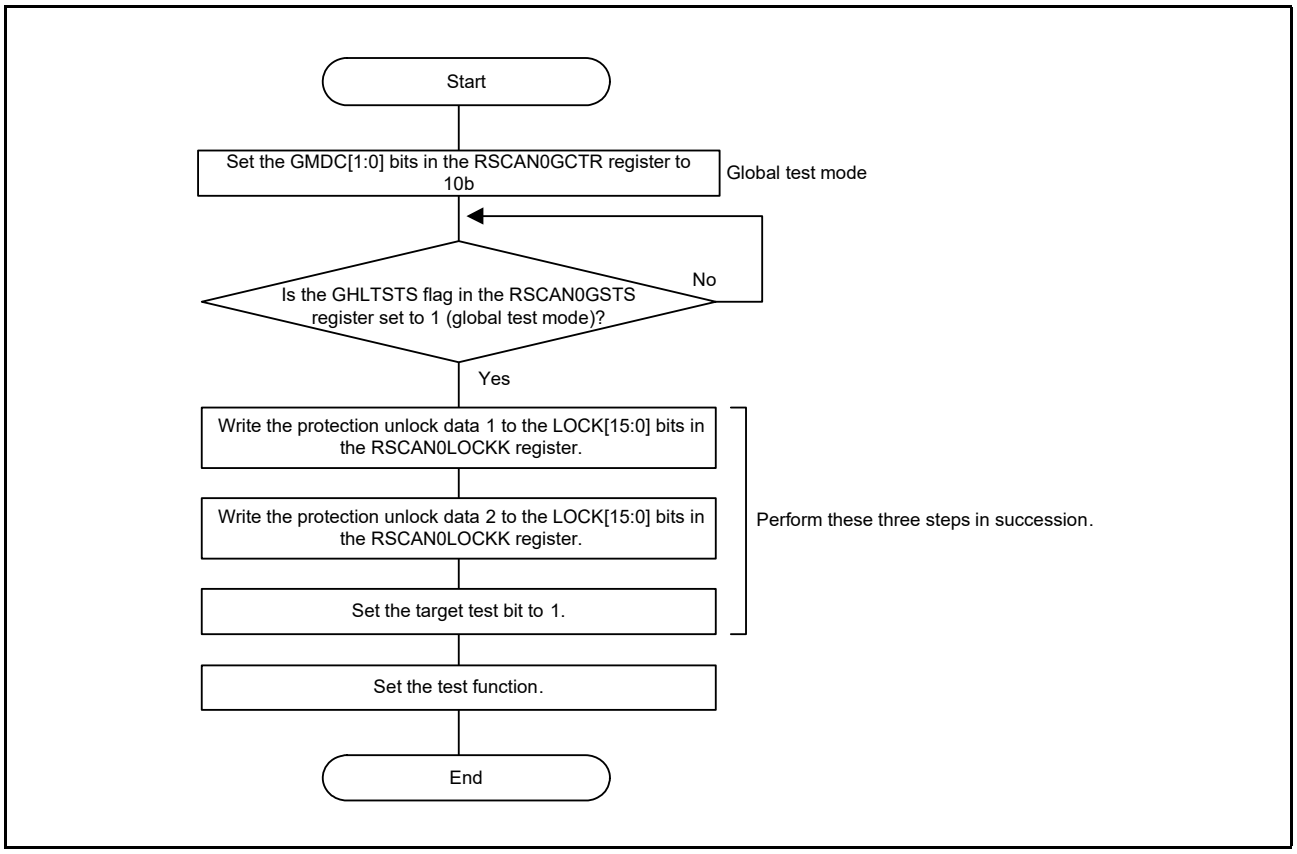

Figure 35.35 Protection Unlock Procedure

35.9.4.3 RAM Test Setting Procedure

RAM tests include CAN RAM read/write test. The read/write test verifies that data written to the RAM is read correctly. Before closing the RAM test, write 0000 0000h to all pages of the CAN RAM.
Figure 35.36 shows the RAM test setting procedure.

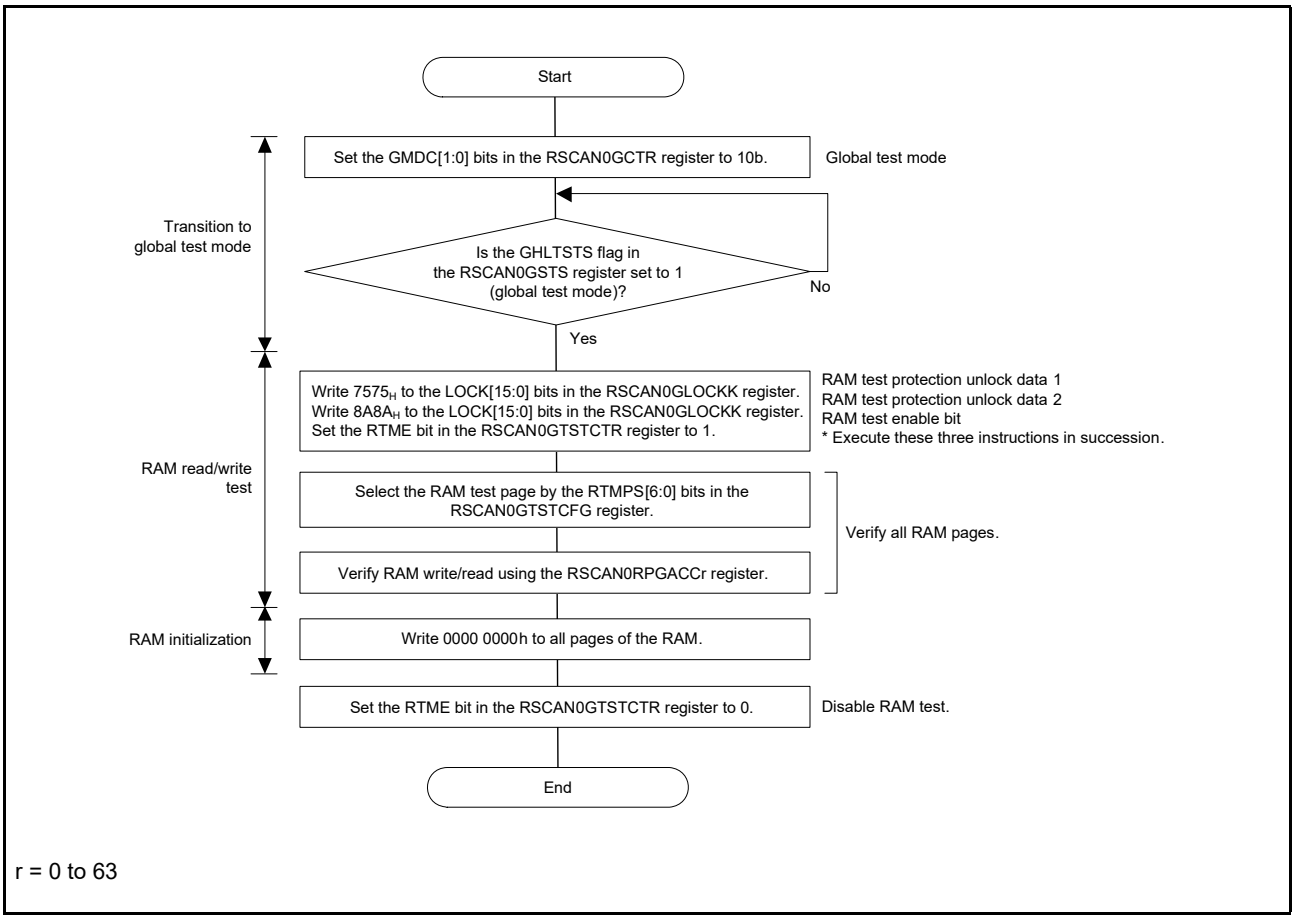

Figure 35.36 RAM Test Setting Procedure

35.9.4.4 Inter-Channel Communication Test Setting Procedure

Communication testing can be performed by transmitting and receiving data between different channels.
Figure 35.37 shows the inter-channel communication test setting procedure.

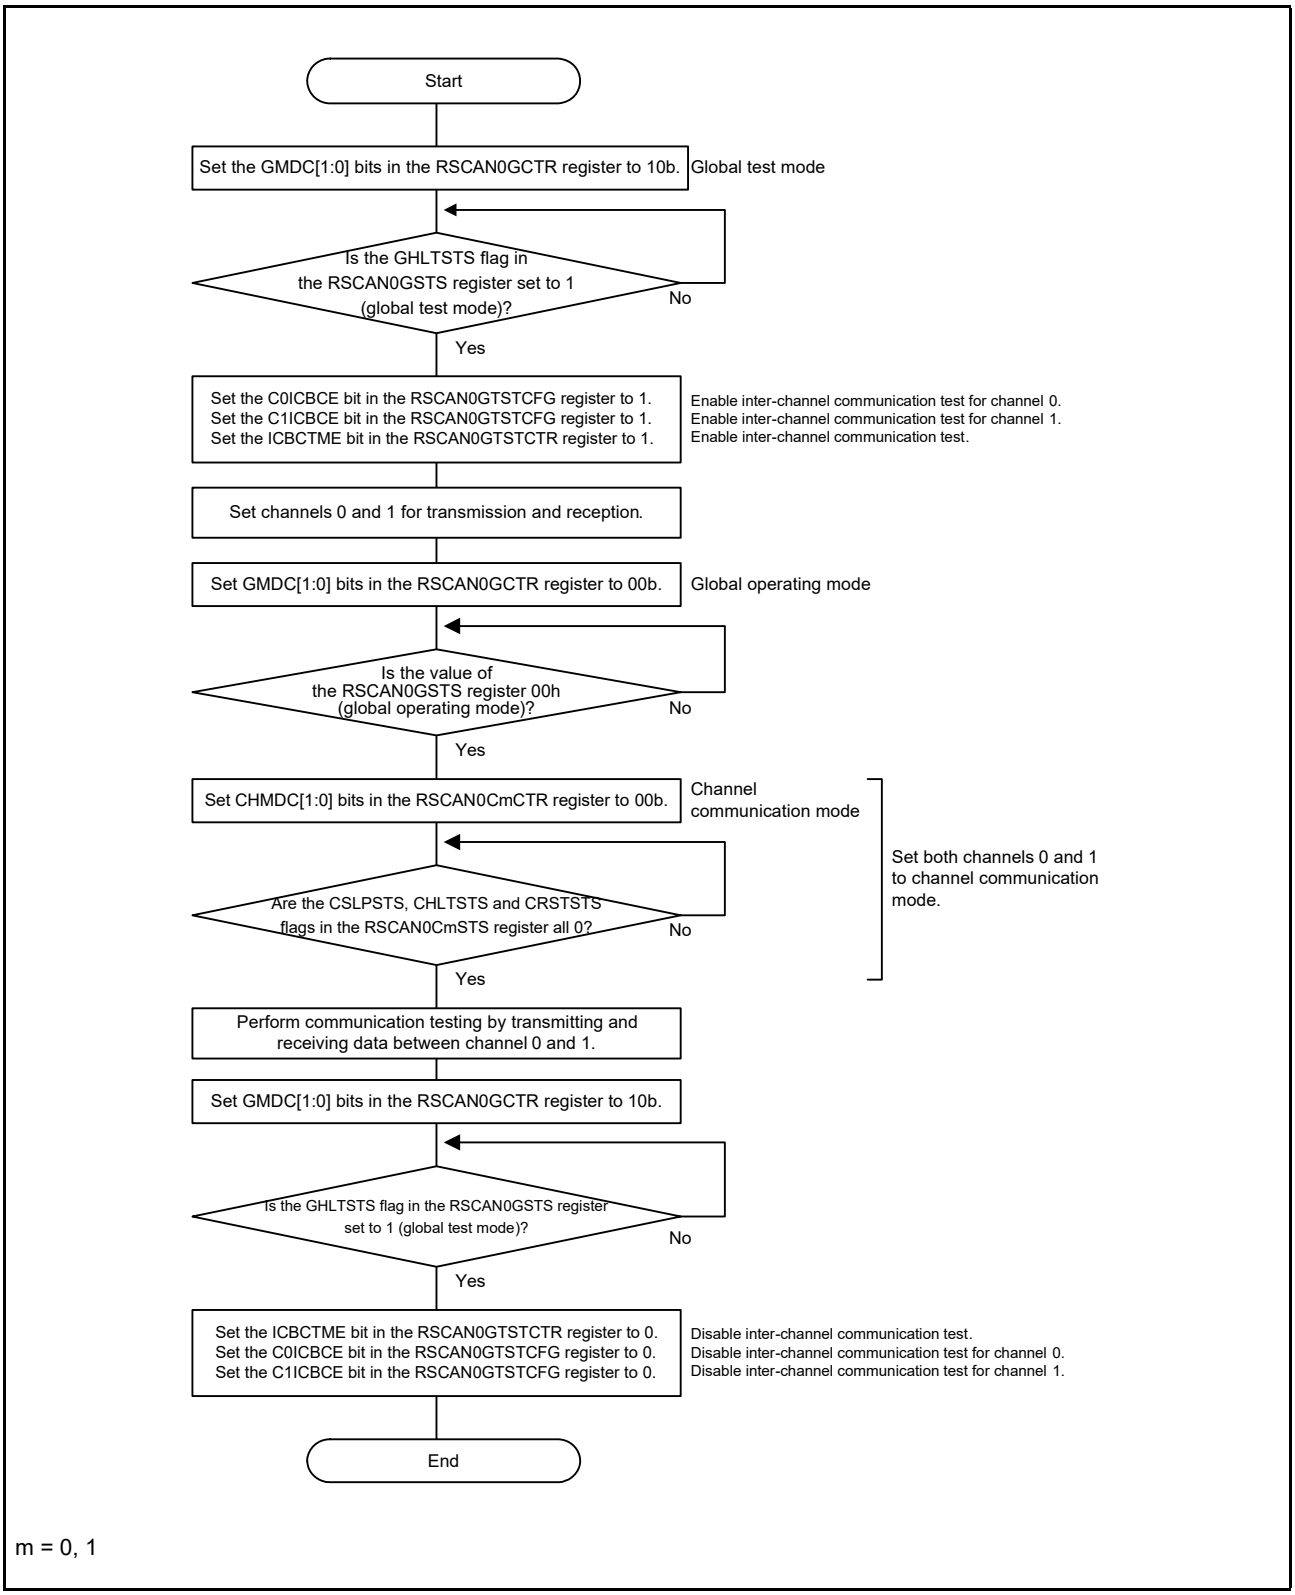

Figure 35.37 Inter-Channel Communication Test Setting Procedure (Example of Communication Test between Channel 0 and Channel 1)

35.10 Detection and Correction of Errors in RSCAN RAM

35.10.1 ECC for the RSCAN RAM

Each buffer RAM of the RSCAN has the following ECC functions.

- ECC error detection/correction
  The RAM is checked for ECC errors. The following options are selectable.
  - 2-bit error detection and 1-bit error detection/correction
  - 2-bit error detection and 1-bit error detection
  The ECC error detection/correction can be disabled by using through mode.
  With the initial settings, error detection/correction is enabled.
- Error notification
  When any of the following errors occurs, it is conveyed to the error control module (ECM).
  - 1-bit ECC error in the RSCAN RAM
  - 2-bit ECC error in the RSCAN RAM
  - RSCAN overflow error
  In the initial setting, 2-bit error notification is enabled. However, if an interrupt is masked by the FEINTFMSK register, interrupt processing does not proceed.
- Error status
  Detection of 2- and 1-bit ECC errors can be monitored.
  A bit for clearing the error status is provided.

Note: When ECC error detection/correction is performed, initialize the RSCAN RAM by the RSCAN module before it is used.

35.10.2 Output of Errors

The RSCAN outputs the following errors to the error control module (ECM) on detection of a 1-bit or 2-bit ECC error and on overflows of the ECCRCANEADz registers (z = 0 to 7), which hold the addresses where ECC errors were detected. For details, see section 42, Error Control Module (ECM).

- 1-bit ECC error in the RSCAN RAM
- 2-bit ECC error in the RSCAN RAM
- RSCAN overflow error

35.11 Notes on the RSCAN Module

- When changing a global mode, check the GSLPSTS, GHLTSTS, and GRSTSTS flags in the RSCAN0GSTS register for transitions. When changing a channel mode, check the CSLPSTS, CHLTSTS, and CRSTSTS flags in the RSCAN0CmSTS register (m = 0, 1) for transitions.
- The acceptance filter processing checks reception rules sequentially in ascending order from the minimum rule number. If the same ID, IDE bit, or RTR bit value is set for multiple reception rules, the minimum number of reception rule is used for the acceptance filter processing. If the message does not pass through the subsequent DLC filter processing, the data processing is terminated without returning to the acceptance filter processing and the message is not stored in the buffer.
- When linking transmission buffers to transmission/reception FIFO buffers or allocating transmission buffers to transmission queues, set the control register (RSCAN0TMCp) of the corresponding transmission buffer to 00h. The status register (RSCAN0TMSTSp) of the corresponding transmission buffer should not be used. Flags in other status registers (registers RSCAN0TMTRSTS0 to RSCAN0TMTRSTS2, RSCAN0TMTARSTS0 to RSCAN0TMTARSTS2, RSCAN0TMTCSTS0 to RSCAN0TMTCSTS2, and RSCAN0TMTASTS0 to RSCAN0TMTASTS2), which correspond to transmission buffers linked to transmission/reception FIFO buffers or allocated to transmission queues remain unchanged. Set the enable bit in the corresponding interrupt enable register (registers RSCAN0TMIEC0 to RSCAN0TMIEC2) to 0 (transmission buffer interrupt is disabled).
- Transmission buffers that are linked to transmission/reception FIFO buffers must not bet allocated to transmission queues.
- Only a single transmission/reception FIFO buffer can be linked to a transmission buffer. Do not link two or more transmission/reception FIFO buffers to transmission buffers of the same number.
- When the CANm bit time clock is selected as a timestamp counter clock source, the timestamp counter stops when the corresponding channel has transitioned to channel reset mode or channel halt mode.
- In case of an attempt to store a new received message when the reception FIFO buffer and the transmission/reception FIFO buffer are full, the new message is discarded. If you wish to store a new message for transmission in the transmission/reception FIFO buffer or the transmission queue, check that the transmission/reception FIFO buffer or the transmission queue is not full.
- The values of unused reception buffers (RSCAN0RMIDq, RSCAN0RMPTRq, RSCAN0RMDF0q, and RSCAN0RMDF1q registers), reception FIFO buffer access registers (RSCAN0RFIDx, RSCAN0RFPTRx, RSCAN0RFDF0x, and RSCAN0RFDF1x registers), and transmission/reception FIFO buffer access registers (RSCAN0CFIDk, RSCAN0CFPTRk, RSCAN0CFDF0k, and RSCAN0CFDF1k registers) are undefined when the RSCAN module transitions to global operation mode or global test mode after exiting from global reset mode.

36. Serial Peripheral Interface (RSPIa)

36.1 Overview

This LSI includes four channels of serial peripheral interface (RSPI).
The RSPI channels are capable of high-speed, full-duplex synchronous serial communications with multiple processors and peripheral devices.
Table 36.1 lists the specifications of the RSPI, and Figure 36.1 shows a block diagram of the RSPI.
In this section, a lower-case letter m in RSPI command register m (SPCMDm) indicates a value from 0 to 7.

Table 36.1 RSPI Specifications (1 / 2)

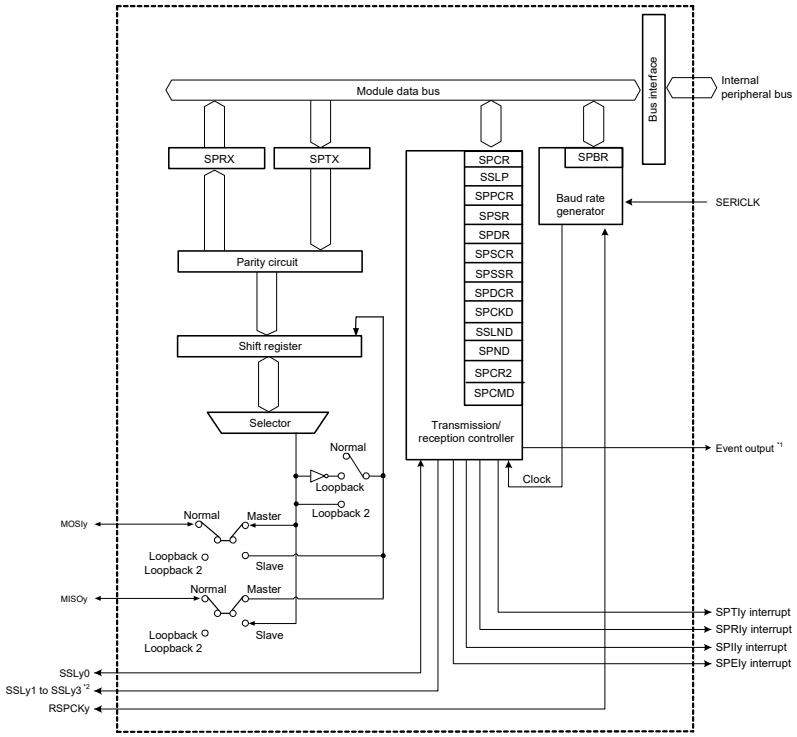
Item	Description
Number of channels	Four channels
RSPI transfer functions	• Use of MOSI (master out/slave in), MISO (master in/slave out), SSL (slave select), and RSPCK (RSPI clock) signals allows serial communications through SPI operation (four-wire method) or clock synchronous operation (three-wire method). • Transmit-only operation is available. • Communication mode: Full-duplex or transmit-only can be selected. • Switching of the polarity of RSPCK • Switching of the phase of RSPCK
Data format	• MSB first/LSB first selectable • Transfer bit length is selectable as 8, 9, 10, 11, 12, 13, 14, 15, 16, 20, 24, or 32 bits. • 128-bit transmission/reception buffers • Up to four frames can be transferred in one round of transmission/reception (each frame consisting of up to 32 bits).
Bit rate	• In master mode, the on-chip baud rate generator generates RSPCK by frequency-dividing SERICLK (the division ratio ranges from divided by 4 to divided by 4096). • In slave mode, the minimum SERICLK clock divided by 8 can be input as RSPCK (the maximum frequency of RSPCK is that of SERICLK divided by 8). Width at high level: 4 cycles of SERICLK; width at low level: 4 cycles of SERICLK
Buffer configuration	• Double buffer configuration for the transmission/reception buffers • 128 bits for the transmission/reception buffers
Error detection	• Mode fault error detection • Overrun error detection*1 • Parity error detection
SSL control function	• Four SSL pins for channel 0 (SSL00 to SSL03), two SSL pins for channel 1 (SSL10, SSL11), and one SSL pin for each of channels 2 and 3 (SSL20, SSL30) • In single-master mode, SSL00 to SSL03, SSL10, SSL11, SSL20, and SSL30 pins are output. • In multi-master mode: SSL00, SSL10, SSL20, and SSL30 pins for input, and SSL01 to SSL03 and SSL11 pins for either output or unused. • In slave mode: SSL00, SSL10, SSL20, and SSL30 pins for input, and SSL01 to SSL03 and SSL11 pins for unused. • Controllable delay from SSL output assertion to RSPCK operation (RSPCK delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable delay from RSPCK stop to SSL output negation (SSL negation delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Controllable wait for next-access SSL output assertion (next-access delay) Range: 1 to 8 RSPCK cycles (set in RSPCK-cycle units) • Function for changing SSL polarity
Control in master transfer	• A transfer of up to eight commands can be executed sequentially in looped execution. • For each command, the following can be set: SSL signal value, bit rate, RSPCK polarity/phase, transfer data length, MSB/LSB first, burst, RSPCK delay, SSL negation delay, and next-access delay • A transfer can be initiated by writing to the transmission buffer. • MOSI signal value specifiable in SSL negation • RSPCK auto-stop function

Table 36.1 RSPI Specifications (2 / 2)

Item	Description
Interrupt sources	• Interrupt sources Reception buffer full interrupt Transmission buffer empty interrupt RSPI error interrupt (mode fault, overrun, parity error) RSPI idle interrupt (RSPI idle)
Event link function*2 (output)	• The following events can be output to the event link controller. Reception buffer full signal Transmission buffer empty signal Mode fault, overrun, or parity error signal RSPI idle signal Transmission-completed signal
Others	• Function for switching between CMOS output and open-drain output • Function for initializing the RSPI • Loopback mode
Low-power consumption function	Module-stop state can be set.

Note 1. In master reception and when the RSPCK auto-stop function is enabled, an overrun error does not occur because the transfer clock is stopped at the timing of overrun error detection.

Note 2. Only for channel 0 (RSPI0)



SPCR:	RSPI control register	SPDCR:	RSPI data control register
SPCR2:	RSPI control register 2	SPCKD:	RSPI clock delay register
SSLP:	RSPI slave select polarity register	SSLND:	RSPI slave select negation delay register
SPPCR:	RSPI pin control register	SPND:	RSPI next-access delay register
SPSR:	RSPI status register	SPCMD:	RSPI command registers 0 to 7 (eight registers)
SPDR:	RSPI data register		
SPSCR:	RSPI sequence control register	SPBR:	RSPI bit rate register
SPSSR:	RSPI sequence status register	SPTX:	RSPI transmission buffer
		SPRX:	RSPI reception buffer

Note 1. Only for channel 0.
Note 2. The number of pins differs for each channel (SSL01 to SSL03 for channel 0; SSL11 for channel 1).
y = 0, 1, 2, 3 (for all channels)

Figure 36.1 RSPI Block Diagram

Table 36.2 lists the I/O pins used in the RSPI.
The RSPI automatically switches the I/O direction of the SSLy0 pin. SSLy0 is set as an output when the RSPI is a single master and as an input when the RSPI is a multi-master or a slave. Pins RSPCKy, MOSIy, and MISOy are automatically set as inputs or outputs according to the setting of master or slave and the level input on the SSLy0 pin.
Refer to section 36.3.2, Controlling RSPI Pins.

Table 36.2 RSPI Pin Configuration

Channel	Pin Name	I/O	Function
RSPI0	RSPCK0	I/O	Clock I/O
	MOSI0	I/O	Master transmit data I/O
	MISO0	I/O	Slave transmit data I/O
	SSL00	I/O	Slave selection signal I/O
	SSL01	Output	Slave selection signal output
	SSL02	Output	Slave selection signal output
	SSL03	Output	Slave selection signal output
RSPI1	RSPCK1	I/O	Clock I/O
	MOSI1	I/O	Master transmit data I/O
	MISO1	I/O	Slave transmit data I/O
	SSL10	I/O	Slave selection signal I/O
	SSL11	Output	Slave selection signal output
RSPI2	RSPCK2	I/O	Clock I/O
	MOSI2	I/O	Master transmit data I/O
	MISO2	I/O	Slave transmit data I/O
	SSL20	I/O	Slave selection signal I/O
RSPI3	RSPCK3	I/O	Clock I/O
	MOSI3	I/O	Master transmit data I/O
	MISO3	I/O	Slave transmit data I/O
	SSL30	I/O	Slave selection signal I/O

Note: The number of SSL pins differs from channel to channel. The indices to identify the channels are from 0 to 3.

36.2 Register Descriptions

36.2.1 RSPI Control Register (SPCR)

The SPCR register controls the settings for operation of the RSPI.
The SPCR.MSTR, SPCR.MODFEN, and SPCR.TXMD bits should be set while the setting of the SPCR.SPE bit is 0. Writing to these bits is prohibited while the setting of the SPCR.SPE bit is 1.

Address(es): RSPI0.SPCR A006 8000h, RSPI1.SPCR A006 8400h, RSPI2.SPCR A006 8800h, RSPI3.SPCR A006 8C00h

	b7	b6	b5	b4	b3	b2	b1	b0
	SPRIE	SPE	SPTIE	SPEIE	MSTR	MODFEN	TXMD	SPMS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPMS	RSPI Mode Select	0: SPI operation (four-wire method) 1: Clock synchronous operation (three-wire method)	R/W
b1	TXMD	Communications Operating Mode Select	0: Full-duplex synchronous serial communications 1: Serial communications consisting of only transmit operations	R/W
b2	MODFEN	Mode Fault Error Detection Enable	0: Disables the detection of mode fault error 1: Enables the detection of mode fault error	R/W
b3	MSTR	Master/Slave Mode Select	0: Slave mode 1: Master mode	R/W
b4	SPEIE	Error Interrupt Enable	0: Disables the generation of error interrupt requests 1: Enables the generation of error interrupt requests	R/W
b5	SPTIE	Transmission Buffer Empty Interrupt Enable	0: Disables the generation of transmission buffer empty interrupt requests 1: Enables the generation of transmission buffer empty interrupt requests	R/W
b6	SPE	RSPI Function Enable	0: Disables the RSPI function 1: Enables the RSPI function	R/W
b7	SPRIE	Reception Buffer Full Interrupt Enable	0: Disables the generation of reception buffer full interrupt requests 1: Enables the generation of reception buffer full interrupt requests	R/W

SPMS Bit (RSPI Mode Select)

The SPMS bit selects SPI operation (four-wire method) or clock synchronous operation (three-wire method).
The SSLy0 to SSLy3 pins are not used in clock synchronous operation. The three pins RSPCKy, MOSIy, and MISOy handle communications. If clock synchronous operation is to proceed in master mode (SPCR.MSTR = 1), the SPCMDm.CPHA bit can be set to either 0 or 1. Set the CPHA bit to 1 if clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0). Do not set the CPHA bit to 0 when clock synchronous operation is to proceed in slave mode (SPCR.MSTR = 0). (y = 0, 1, 2, 3)

TXMD Bit (Communications Operating Mode Select)

The TXMD bit selects the operation for full-duplex synchronous serial communications or the operation for transmission only.
When performing communications with the TXMD bit set to 1, the RSPI performs only transmit operations and not receive operations (refer to section 36.3.6, Communications Operating Mode).
When the TXMD bit is set to 1, reception buffer full interrupt requests cannot be used.

MODFEN Bit (Mode Fault Error Detection Enable)

The MODFEN bit enables or disables the detection of mode fault error (refer to section 36.3.8, Error Detection). In addition, the RSPI determines the I/O direction of the SSLy0 to SSLy3 (y = 0, 1, 2, 3) pins based on combinations of the MODFEN and MSTR bits (refer to section 36.3.2, Controlling RSPI Pins).

MSTR Bit (RSPI Master/Slave Mode Select)

The MSTR bit selects master/slave mode of the RSPI. According to MSTR bit settings, the RSPI determines the direction of pins RSPCKy, MOSIy, and MISOy, and SSLy0 to SSLy3 (y = 0, 1, 2, 3).

SPEIE Bit (RSPI Error Interrupt Enable)

The SPEIE bit enables or disables the generation of RSPI error interrupt requests when the RSPI detects a mode fault error and sets the SPSR.MODF flag to 1, when the RSPI detects an overrun error and sets the SPSR.OVRF flag to 1, or when the RSPI detects a parity error and sets the SPSR.PERF flag to 1 (refer to section 36.3.8, Error Detection).

SPTIE Bit (Transmission Buffer Empty Interrupt Enable)

The SPTIE bit enables or disables a transmission buffer empty interrupt request generated when the RSPI detects that the transmission buffer is empty.
If the RSPI function is disabled (i.e. the SPE bit is set to 0), the transmission buffer being empty is detected. If the SPTIE bit is set to 1 at this time, a transmission buffer empty interrupt is generated.
Note that a transfer buffer empty interrupt request is also generated when the SPTIE and SPE bits are set to 1 at the same time at the start of transmission.

SPE Bit (RSPI Function Enable)

The SPE bit enables or disables the RSPI function.
When the SPSR.MODF bit is 1, the SPE bit cannot be set to 1. For details, refer to section 36.3.8, Error Detection.
Setting the SPE bit to 0 disables the RSPI function, and initializes a part of the module function. For details, refer to section 36.3.9, Initializing RSPI. Furthermore, when the setting of the SPTIE bit is 1 (enabling the generation of transmission buffer empty interrupts), a transmission buffer empty interrupt request is generated by the state of the SPE bit changing from 0 to 1 or from 1 to 0.

SPRIE Bit (RSPI Reception Buffer Full Interrupt Enable)

The SPRIE bit enables or disables RSPI reception buffer full interrupt requests when the RSPI has detected the reception buffer being full after the completion of a serial transfer.

36.2.2 RSPI Slave Select Polarity Register (SSLP)

The SSLP register controls the active sense of the RSPIy (y = 0, 1, 2, 3) slave select signals.
The SSLP register should be set while the setting of the SPCR.SPE bit is 0. Writing to this register is prohibited while the setting of the SPCR.SPE bit is 1.

Address(es): RSPI0.SSLP A006 8001h, RSPI1.SSLP A006 8401h, RSPI2.SSLP A006 8801h, RSPI3.SSLP A006 8C01h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SSL3P	SSL2P	SSL1P	SSL0P
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSL0P	SSL0 Signal Polarity Setting	0: SSLy0 signal is active low 1: SSLy0 signal is active high	R/W
b1	SSL1P	SSL1 Signal Polarity Setting*1	0: SSLy1 signal is active low 1: SSLy1 signal is active high	R/W
b2	SSL2P	SSL2 Signal Polarity Setting*2	0: SSLy2 signal is active low 1: SSLy2 signal is active high	R/W
b3	SSL3P	SSL3 Signal Polarity Setting*2	0: SSLy3 signal is active low 1: SSLy3 signal is active high	R/W
b7 to b4	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. Bits for channels 2 and 3 are reserved. These bits are read as 0. The write value should be 0.
Note 2. Bits for channels 1, 2, and 3 are reserved. These bits are read as 0. The write value should be 0.

36.2.3 RSPI Pin Control Register (SPPCR)

The SPPCR register controls the output setting for RSPI output pins.

The SPPCR register should be set while the setting of the SPCR.SPE bit is 0. Writing to this register is prohibited while the setting of the SPCR.SPE bit is 1.

Address(es): RSPI0.SPPCR A006 8002h, RSPI1.SPPCR A006 8402h, RSPI2.SPPCR A006 8802h, RSPI3.SPPCR A006 8C02h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	MOIFE	MOIFV	—	SPOM	SPLP2	SPLP
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPLP	RSPI Loopback	0: Normal mode 1: Loopback mode (data is inverted for transmission)	R/W
b1	SPLP2	RSPI Loopback 2	0: Normal mode 1: Loopback mode (data is not inverted for transmission)	R/W
b2	SPOM	Output Pin Mode	0: CMOS output 1: Open-drain output	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	MOIFV	MOSI Idle Fixed Value	0: The level output on the MOSIy pin during MOSI idling corresponds to low. 1: The level output on the MOSIy pin during MOSI idling corresponds to high.	R/W
b5	MOIFE	MOSI Idle Value Fixing Enable	0: MOSI output value equals final data from previous transfer 1: MOSI output value equals the value set in the MOIFV bit	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPLP Bit (RSPI Loopback)

The SPLP bit selects the mode of the RSPI pins.

When the SPLP bit is set to 1, the RSPI shuts off the path between the MISOy pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIy pin and the shift register if the SPCR.MSTR bit is 0, and connects (inverts) the input path and output path for the shift register (loopback mode).

(y = 0, 1, 2, 3)

SPLP2 Bit (RSPI Loopback 2)

The SPLP2 bit selects the mode of the RSPI pins.

When the SPLP2 bit is set to 1, the RSPI shuts off the path between the MISOy pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIy pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path for the shift register (loopback mode).

(y = 0, 1, 2, 3)

SPOM Bit (Output Pin Mode)

The SPOM bit is used to set the RSPI output pins to CMOS output or open-drain output. For details, see section 36.3.2, Controlling RSPI Pins.

MOIFV Bit (MOSI Idle Fixed Value)

If the MOIFE bit is 1 in master mode, the MOIFV bit determines the MOSIy pin output value as low or high during the SSL negation period (including the SSL retention period during a burst transfer).

MOIFE Bit (MOSI Idle Value Fixing Enable)

The MOIFE bit selects whether the MOSIy output level is to be fixed over the SSL negation period (including the SSL retention period during a burst transfer) when the RSPI is in master mode. When the MOIFE bit is 0, the RSPI continues to output the value of the last bit from the previous serial transfer during the SSL negation period to the MOSIy pin. When the MOIFE bit is 1, the RSPI outputs a fixed low or high level on the MOSIy pin according to the setting of the MOIFV bit.
(y = 0, 1, 2, 3)

36.2.4 RSPI Status Register (SPSR)

The SPSR register indicates the state of RSPI transfer.

Address(es): RSPI0.SPSR A006 8003h, RSPI1.SPSR A006 8403h, RSPI2.SPSR A006 8803h, RSPI3.SPSR A006 8C03h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	PERF	MODF	IDLNF	OVRF
Value after reset:	x	0	x	0	0	0	0	0

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	OVRF	Overrun Error Flag	0: No overrun error occurs 1: An overrun error occurs	R/(W) *1
b1	IDLNF	RSPI Idle Flag	0: RSPI is in the idle state 1: RSPI is in the transfer state	R
b2	MODF	Mode Fault Error Flag	0: No mode fault error occurs 1: A mode fault error occurs	R/(W) *1
b3	PERF	Parity Error Flag	0: No parity error occurs 1: A parity error occurs	R/(W) *1
b4	—	Reserved	This bit is read as 0. The write value should be 0.	R/(W)
b5	—	Reserved	The read value is undefined. The write value should be 1.	R/(W)
b6	—	Reserved	This bit is read as 0. The write value should be 0.	R/(W)
b7	—	Reserved	The read value is undefined. The write value should be 1.	R/(W)

Note 1. Only 0 can be written to clear the flag after reading 1.

OVRF Flag (Overrun Error Flag)

The OVRF flag indicates the occurrence of an overrun error. In master mode (when the SPCR.MSTR bit is 1) and when the RSPCK clock auto-stop function is enabled (the SPCR1.SCKASE bit is 1), an overrun error does not occur; accordingly this flag does not become 1. For details, see section 36.3.8.1, Overrun Error.

[Setting condition]

- When the next serial transfer ends while the SPCR.TXMD bit is 0 and the reception buffer is full.

[Clearing condition]

- When SPSR is read while the OVRF flag is 1, and then writes the value 0 to the OVRF flag.

IDLNF Flag (RSPI Idle Flag)

The IDLNF flag indicates the transfer status of the RSPI.

[Setting condition]

Master mode

- Condition 1 and condition 2 are not satisfied in master mode under the [Clearing condition] below.

Slave mode

- The SPCR.SPE bit is 1 (RSPI function is enabled)

[Clearing condition]

Master mode

The following 1 is satisfied (condition 1) or all of the following 2 to 4 are satisfied (condition 2).

1. The SPCR.SPE bit is 0 (RSPI is initialized)
2. The transmission buffer (SPTX) is empty (data for the next transfer is not set)
3. The SPSSR.SPCP[2:0] bits are 000b (beginning of sequence control)
4. The RSPI internal sequencer has entered the idle state (status in which operations up to the next-access delay have finished)

Slave mode

- The SPCR.SPE bit is 0 (RSPI is initialized)

MODF Flag (Mode Fault Error Flag)

Indicates the occurrence of a mode fault error.

[Setting condition]

Multi-master mode

- When the input level of the SSLyi pin changes to the active level while the SPCR.MSTR bit is 1 (master mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error

Slave mode

- When the SSLyi pin is negated before the RSPCK cycle necessary for data transfer ends while the SPCR.MSTR bit is 0 (slave mode) and the SPCR.MODFEN bit is 1 (mode fault error detection is enabled), the RSPI detects a mode fault error

The active level of the SSLyi signal is determined by the SSLP.SSLiP bit (SSLi signal polarity setting bit).

(y = 0, 1, 2, 3 (for all channels); i = 0 to 3)

[Clearing condition]

- When SPSR is read while the MODF flag is 1, and then writes the value 0 to the MODF flag

PERF Flag (Parity Error Flag)

Indicates the occurrence of a parity error.

[Setting condition]

- When a serial transfer ends while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1, the RSPI detects a parity error

[Clearing condition]

- When SPSR is read while the PERF flag is 1, and then writes the value 0 to the PERF flag

36.2.5 RSPI Data Register (SPDR)

SPDR is the interface with the buffers that hold data for transmission and reception by the RSPI.
When accessing in longwords (the SPLW bit is 1), access SPDR.
When accessing in words (the SPLW bit is 0), access the higher-order 16 bits (H) of SPDR.

Address(es): RSPI0.SPDR A006 8004h, RSPI1.SPDR A006 8404h, RSPI2.SPDR A006 8804h, RSPI3.SPDR A006 8C04h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

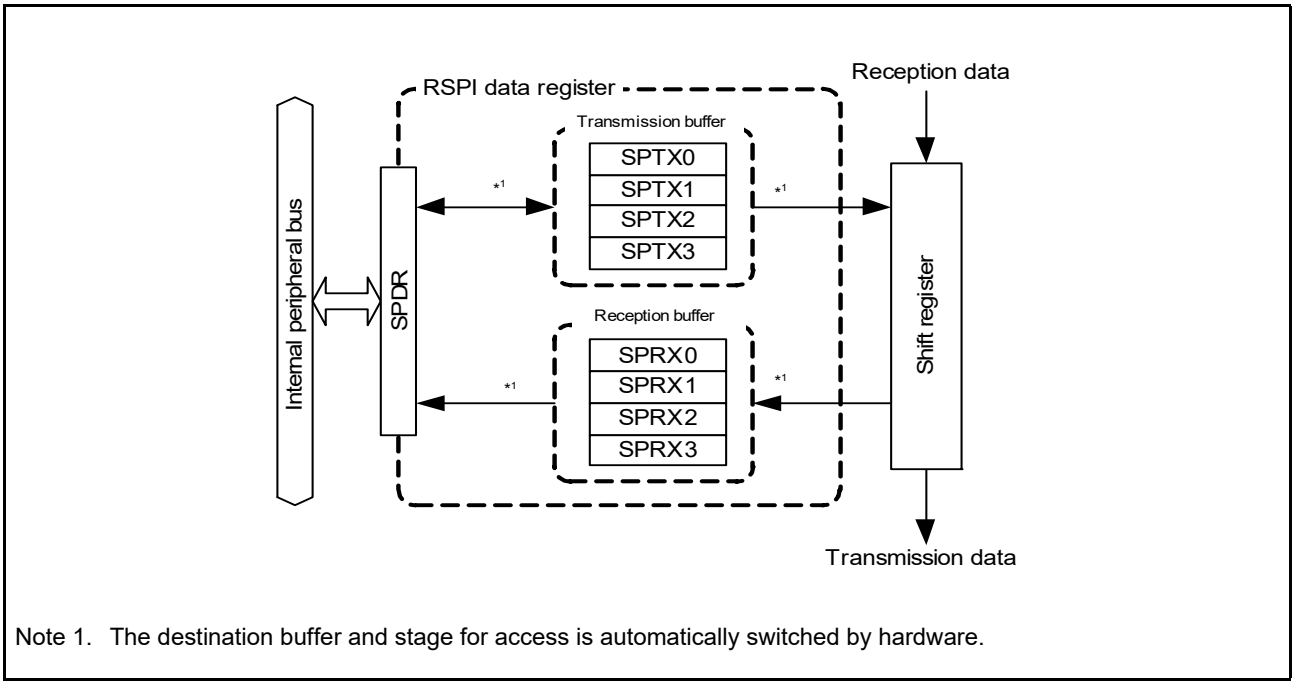
	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Address(es): RSPI0.SPDR A006 8004h, RSPI1.SPDR A006 8404h, RSPI2.SPDR A006 8804h, RSPI3.SPDR A006 8C04h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	H															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

The transmission buffer (SPTX) and reception buffer (SPRX) are independent but are both mapped to SPDR. Figure 36.2 shows the configuration of SPDR.



Note 1. The destination buffer and stage for access is automatically switched by hardware.

Figure 36.2 Configuration of SPDR

The transmit and reception buffers each have four stages. The number of stages to be used is selectable by the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]). The eight stages of the buffer are all mapped to the single address of SPDR.
Data written to SPDR are written to a transmission-buffer stage (SPTXn) (n = 0 to 3) and then transmitted from the buffer. The reception buffer holds received data on completion of reception. The reception buffer is not updated if an overrun is generated.
Furthermore, if the data length is other than 32 bits, bits not referred to in SPTXn (n = 0 to 3) are stored in the corresponding bits in SPRXn (n = 0 to 3). For example, if the data length is 9 bits, received data are stored in the SPRXn[8:0] bits and the SPTXn[31:9] bits are stored in the SPRXn[31:9] bits.

(1) Bus Interface

SPDR is the interface with 32-bit wide transmit and reception buffers, each of which has four stages, for a total of 32 bytes. In other words, the 32 bytes are mapped to the 4-byte address space for SPDR. Furthermore, the unit of access for SPDR is selected by the RSPI longword access/word access specification bit in the RSPI data control register (SPDCR.SPLW).
Data for transmission should be flush with the LSB end of the register. Received data are stored flush with the LSB end.
Operations involved in writing to and reading from SPDR are described below.

(a) Writing

Data written to SPDR are written to a transmission buffer (SPTXn). This is not influenced by the value of the SPDCR.SPRDTD bit unlike when reading from SPDR.
The transmission buffer includes a transmission buffer write pointer which is automatically updated to indicate the next stage each time data are written to SPDR.
Figure 36.3 shows the configuration of the bus interface with the transmission buffer in the case of writing to SPDR.

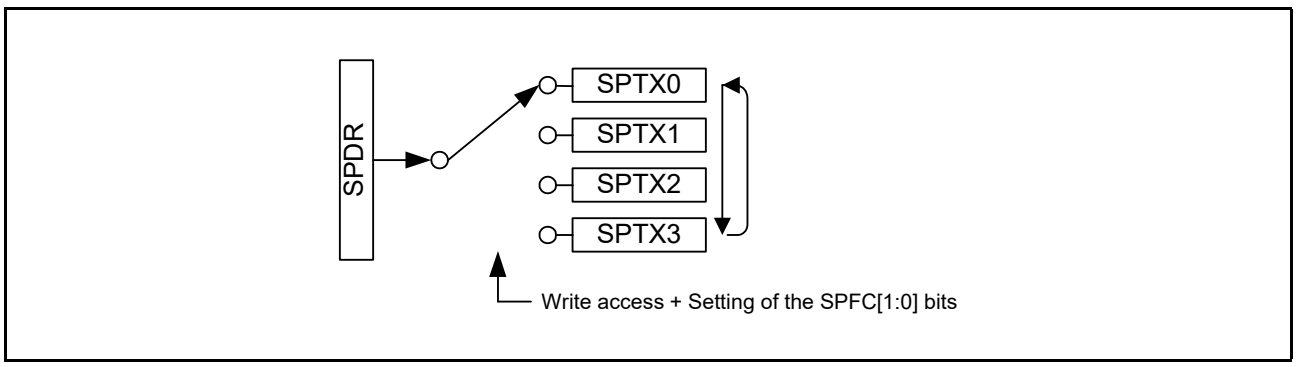


Figure 36.3 Configuration of SPDR (Writing)

The sequence for switching the transmission buffer write pointer differs with the setting of the number of frames specification bits in the RSPI data control register (SPDCR.SPFC[1:0]).

- Settings of the SPFC[1:0] bits and sequence of switching the pointer among SPTX0 to SPTX3.
  When the SPFC[1:0] bits are 00b: SPTX0 → SPTX0 → SPTX0 → …
  When the SPFC[1:0] bits are 01b: SPTX0 → SPTX1 → SPTX0 → SPTX1 → …
  When the SPFC[1:0] bits are 10b: SPTX0 → SPTX1 → SPTX2 → SPTX0 → SPTX1 → …
  When the SPFC[1:0] bits are 11b: SPTX0 → SPTX1 → SPTX2 → SPTX3 → SPTX0 → SPTX1 → …

When 1 is written to the RSPI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 0, SPTX0 will be the destination the next time writing proceeds.
When writing to the transmission buffer (SPTXn) after generation of the transmission buffer empty interrupt, write the number of frames set by the number of frames specification bits (SPFC[1:0]) in the RSPI data control register (SPDCR). Even if the number of frames is written to the transmission buffer (SPTXn), the value of the buffer is not updated after completion of the writing and before generation of the next transmission buffer empty interrupt.

(b) Reading

SPDR can be read to read the value of a reception buffer (SPRXn) or a transmission buffer (SPTXn). The setting of the RSPI receive/transmit data selection bit in the RSPI data control register (SPDCR.SPRDTD) selects whether reading is of the receive or transmission buffer.
The sequence of reading the SPDR register is controlled by independent pointers, reception buffer read pointer and transmission buffer read pointer.
Figure 36.4 shows the configuration of the bus interface with the receive and transmission buffers in the case of reading from SPDR.

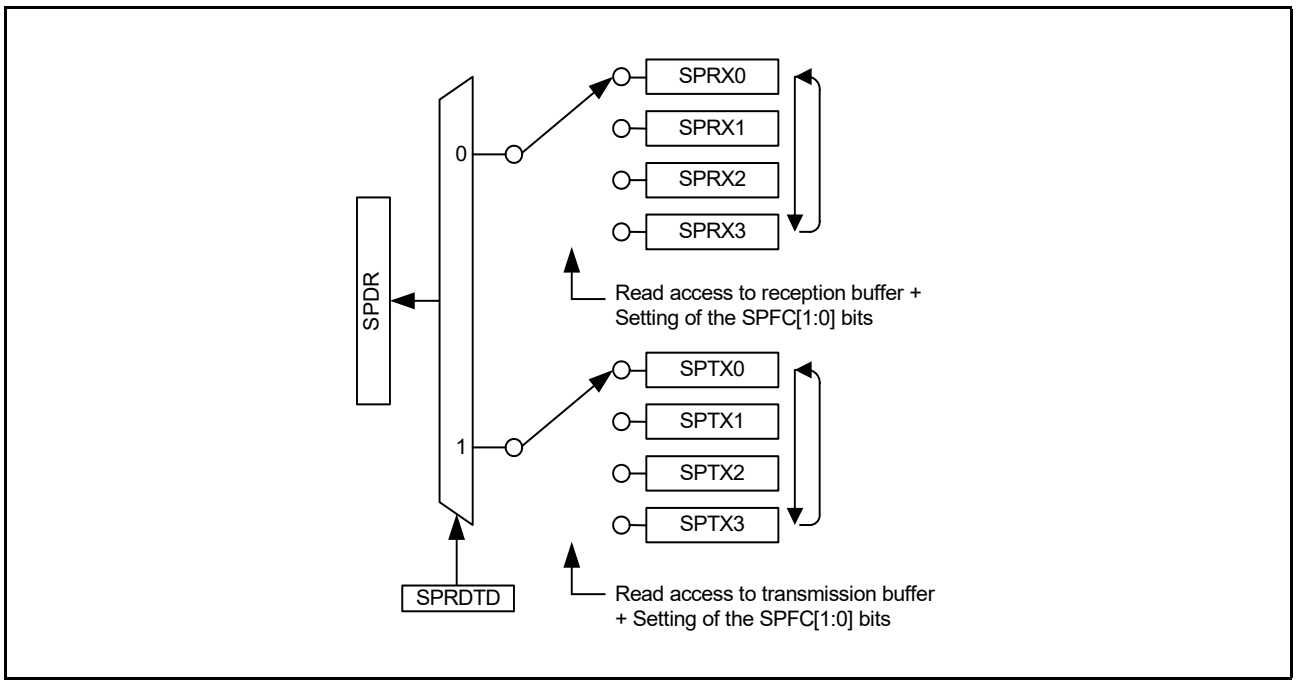

Figure 36.4 Configuration of SPDR (Reading)

Reading the reception buffer switches the reception buffer read pointer to the next buffer automatically.
The sequence of switching the reception buffer read pointer is the same as that for the transmission buffer write pointer. However, when 1 is written to the RSRI function enable bit in the RSPI control register (SPCR.SPE) while the bit's current value is 1, SPRX0 will be indicated by the buffer read pointer the next time reading proceeds.
The transmission buffer read pointer is updated when writing to SPDR, and not updated when reading from the transmission buffer. When reading from the transmission buffer, the value most recently written to SPDR is read. However, after generation of the transmission buffer empty interrupt, the values read from the transmission buffer are all 0 in the interval after completion of writing the number of frames of data specified in the number of frames specification bits (SPDCR.SPFC[1:0]) and before generation of the next buffer empty interrupt.

36.2.6 RSPI Sequence Control Register (SPSCR)

SPSCR sets the sequence length when the RSPI operates in master mode. When changing the SPSCR.SPSLN[2:0] bits while both the SPCR.MSTR and SPCR.SPE bits are 1, the bits should be changed while the SPSR.IDLNF flag is 0.

Address(es): RSPI0.SPSCR A006 8008h, RSPI1.SPSCR A006 8408h, RSPI2.SPSCR A006 8808h, RSPI3.SPSCR A006 8C08h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPSLN[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPSLN[2:0]	RSPI Sequence Length Specification	b2 b0 Sequence Length — Referenced SPCMD0 to SPCMD7 (No.) 0 0 0: 1 — 0→0→… 0 0 1: 2 — 0→1→0→… 0 1 0: 3 — 0→1→2→0→… 0 1 1: 4 — 0→1→2→3→0→… 1 0 0: 5 — 0→1→2→3→4→0→… 1 0 1: 6 — 0→1→2→3→4→5→0→… 1 1 0: 7 — 0→1→2→3→4→5→6→0→… 1 1 1: 8 — 0→1→2→3→4→5→6→7→0→… The order in which the SPCMD0 to SPCMD07 registers are to be referenced is changed in accordance with the sequence length that is set in these bits. The relationship among the setting of these bits, sequence length, and SPCMD0 to SPCMD7 registers referenced by the RSPI is shown above. However, the RSPI in slave mode always references SPCMD0.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPSLN[2:0] Bits (RSPI Sequence Length Specification)

The SPSLN[2:0] bits specify a sequence length when the RSPI in master mode performs sequential operations. The RSPI in master mode changes SPCMD0 to SPCMD7 registers to be referenced and the order in which they are referenced according to the sequence length that is set in the SPSLN[2:0] bits.

In slave mode, SPCMD0 is always referred to.

36.2.7 RSPI Sequence Status Register (SPSSR)

SPSSR indicates the sequence control status when the RSPI operates in master mode.
Any writing to SPSSR is ignored.

Address(es): RSPI0.SPSSR A006 8009h, RSPI1.SPSSR A006 8409h, RSPI2.SPSSR A006 8809h, RSPI3.SPSSR A006 8C09h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	SPECM[2:0]			—	SPCP[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPCP[2:0]	RSPI Command Pointer	b2 b0 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b3	—	Reserved	This bit is read as 0.	R
b6 to b4	SPECM[2:0]	RSPI Error Command	b6 b4 0 0 0: SPCMD0 0 0 1: SPCMD1 0 1 0: SPCMD2 0 1 1: SPCMD3 1 0 0: SPCMD4 1 0 1: SPCMD5 1 1 0: SPCMD6 1 1 1: SPCMD7	R
b7	—	Reserved	This bit is read as 0.	R

SPCP[2:0] Bits (RSPI Command Pointer)

The SPCP[2:0] bits indicate SPCMDm that is currently pointed to by the pointer during sequence control by the RSPI. For the RSPI's sequence control, refer to section 36.3.10.1, Master Mode Operation.

SPECM[2:0] Bits (RSPI Error Command)

The SPECM[2:0] bits indicate SPCMDm that is specified by the SPCP[2:0] bits when an error is detected during sequence control by the RSPI. The RSPI updates the SPECM[2:0] bits only when an error is detected. If both the SPSR.OVRF and SPSR.MODF bits are 0 and there is no error, the values of the SPECM[2:0] bits have no meaning. For the RSPI's error detection function, refer to section 36.3.8, Error Detection. For the RSPI's sequence control, refer to section 36.3.10.1, Master Mode Operation.

36.2.8 RSPI Bit Rate Register (SPBR)

SPBR controls the bit rate settings in master mode. Writing to SPBR is prohibited while both the SPCR.MSTR and SPCR.SPE bits are 1.

Address(es): RSPI0.SPBR A006 800Ah, RSPI1.SPBR A006 840Ah, RSPI2.SPBR A006 880Ah, RSPI3.SPBR A006 8C0Ah

When the RSPI is used in slave mode, the bit rate depends on the bit rate of the input clock (bit rate satisfying the electrical characteristics should be used) regardless of the settings of SPBR and the SPCMDm.BRDV[1:0] bits (bit rate division setting bits).
The bit rate is determined by combinations of the SPBR setting and the SPCMDm.BRDV[1:0] bit setting. The equation for calculating the bit rate is given below. In the equation, n denotes an SPBR setting (0, 1, 2, …, 255), and N denotes a BRDV[1:0] bit setting (0, 1, 2, 3) (m = 0 to 7). However, setting n = 0 (SPR[7:0] = 0) and N = 0 (BRDV[1:0] = 0) is prohibited.

$$\text{Bit rate} = \frac{f\,(\text{SERICLK})}{2 \times (n + 1)\, 2^{N}}$$

Table 36.3 lists examples of the relationship among the SPBR settings, the BRDV[1:0] settings, and bit rates.

Table 36.3 Relationship among SPBR Settings, BRDV[1:0] Settings, and Bit Rates

			Bit Rate	
SPBR (n)	**BRDV[1:0] Bits (N)**	**Division Ratio**	**SERICLK = 120 MHz**	**SERICLK = 150 MHz**
0	0	2	Setting prohibited	Setting prohibited
1	0	4	30.0 Mbps	37.5 Mbps
2	0	6	20.0 Mbps	25.0 Mbps
3	0	8	15.0 Mbps	18.8 Mbps
4	0	10	12.0 Mbps	15.0 Mbps
5	0	12	10.0 Mbps	12.5 Mbps
5	1	24	5.00 Mbps	6.25 Mbps
5	2	48	2.50 Mbps	3.13 Mbps
5	3	96	1.25 Mbps	1.56 Mbps
255	3	4096	29.3 kbps	36.6 kbps

Note: The settings must not exceed the range of electrical characteristics.

36.2.9 RSPI Data Control Register (SPDCR)

SPDCR controls data in the SPDR register.

Up to four frames can be transmitted or received in one round of transmission or reception activation (m = 0 to 7). The amount of data in each transfer is controlled by the combination of the SPCMDm.SPB[3:0] bits, the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits.

When changing the SPDCR.SPFC[1:0] bits while the SPCR.SPE bit is 1, the bits should be changed while the SPSR.IDLNF flag is 0.

Address(es): RSPI0.SPDCR A006 800Bh, RSPI1.SPDCR A006 840Bh, RSPI2.SPDCR A006 880Bh, RSPI3.SPDCR A006 8C0Bh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	SPLW	SPRDTD	—	—	SPFC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	SPFC[1:0]	Number of Frames Specification	b1 b0 0 0: 1 frame 0 1: 2 frames 1 0: 3 frames 1 1: 4 frames	R/W
b3, b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	SPRDTD	RSPI Receive/Transmit Data Selection	0: SPDR values are read from the reception buffer 1: SPDR values are read from the transmission buffer (but only if the transmission buffer is empty)	R/W
b5	SPLW	RSPI Longword Access/ Word Access Specification	0: SPDR is accessed in words 1: SPDR is accessed in longwords	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPFC[1:0] Bits (Number of Frames Specification)

The SPFC[1:0] bits specify the number of frames that can be stored in SPDR (per transfer activation). Up to four frames can be transmitted or received in one round of transmission or reception, and the amount of data is determined by the combination of the SPSCR.SPSLN[2:0] bits, and the SPDCR.SPFC[1:0] bits. Furthermore, the setting of the SPFC[1:0] bits adjusts the number of frames for generation of RSPI reception buffer full interrupt, and start of transmission or generation of transmission buffer empty interrupts. Table 36.4 lists the frame configurations that can be stored in SPDR and examples of combinations of settings for transmission and reception. Combinations of settings other than those shown in the examples should not be made.

Table 36.4 Settable Combinations of SPSLN[2:0] Bits and SPFC[1:0] Bits

Setting	SPSLN[2:0]	SPFC[1:0]	Number of Frames in a Single Sequence	Number of Frames at which Reception Buffer Full Interrupt Occurs or Transmission Buffer Holding Data is Recognized
1-1	000b	00b	1	1
1-2	000b	01b	2	2
1-3	000b	10b	3	3
1-4	000b	11b	4	4
2-1	001b	01b	2	2
2-2	001b	11b	4	4
3	010b	10b	3	3
4	011b	11b	4	4
5	100b	00b	5	1
6	101b	00b	6	1
7	110b	00b	7	1
8	111b	00b	8	1

SPRDTD Bit (RSPI Receive/Transmit Data Selection)

The SPRDTD bit selects whether the SPDR reads values from the reception buffer or from the transmission buffer.
If reading is from the transmission buffer, the value written to SPDR register immediately beforehand is read.
When reading the transmission buffer, do so before writing of the number of frames set in the SPFC[1:0] bits is finished and after generation of the transmission buffer empty interrupt.
For details, refer to section 36.2.5, RSPI Data Register (SPDR).

SPLW Bit (RSPI Longword Access/Word Access Specification)

The SPLW bit specifies the access width for SPDR. Access to SPDR is in words when the SPLW bit is 0 and in longwords when the SPLW bit is 1.
Also, when the SPLW bit is 0, set the SPCMDm.SPB[3:0] bits (RSPI data length setting bits) to 8 to 16 bits. Setting these bits to 20, 24, or 32 bits is prohibited.

36.2.10 RSPI Clock Delay Register (SPCKD)

SPCKD sets a period from the beginning of SSLyi signal assertion to RSPCK oscillation (RSPCK delay) when the SPCMDm.SCKDEN bit is 1. While both the SPCR.MSTR and SPCR.SPE bits are 1, do not change the value of the SPCKD register (m = 0 to 7; y = 0, 1, 2, 3 (for all channels); i = 0 to 3).

Address(es): RSPI0.SPCKD A006 800Ch, RSPI1.SPCKD A006 840Ch, RSPI2.SPCKD A006 880Ch, RSPI3.SPCKD A006 8C0Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SCKDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	RSPCK Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SCKDL[2:0] Bits (RSPCK Delay Setting)

The SCKDL[2:0] bits set an RSPCK delay value when the SPCMDm.SCKDEN bit is 1.
When using the RSPI in slave mode, set the SCKDL[2:0] bits to 000b.

36.2.11 RSPI Slave Select Negation Delay Register (SSLND)

SSLND sets a period (SSL negation delay) from the transmission of a final RSPCK edge to the negation of the SSLyi signal during a serial transfer by the RSPI in master mode. Writing to SSLND is prohibited while both the SPCR.MSTR and SPCR.SPE bits are 1 (y = 0, 1, 2, 3 (for all channels); i = 0 to 3).

Address(es): RSPI0.SSLND A006 800Dh, RSPI1.SSLND A006 840Dh, RSPI2.SSLND A006 880Dh, RSPI3.SSLND A006 8C0Dh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SLNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SLNDL[2:0]	SSL Negation Delay Setting	b2 b0 0 0 0: 1 RSPCK 0 0 1: 2 RSPCK 0 1 0: 3 RSPCK 0 1 1: 4 RSPCK 1 0 0: 5 RSPCK 1 0 1: 6 RSPCK 1 1 0: 7 RSPCK 1 1 1: 8 RSPCK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SLNDL[2:0] Bits (SSL Negation Delay Setting)

The SLNDL[2:0] bits set an SSL negation delay value when the RSPI is in master mode.
When using the RSPI in slave mode, set the SLNDL[2:0] bits to 000b.

36.2.12 RSPI Next-Access Delay Register (SPND)

SPND sets a non-active period (next-access delay) of the SSLyi signal after termination of a serial transfer when the SPCMDm.SPNDEN bit is 1. Writing to SPND is prohibited while both the SPCR.MSTR and SPCR.SPE bits are 1 (m = 0 to 7, y = 0, 1, 2, 3 (for all channels); i = 0 to 3).

Address(es): RSPI0.SPND A006 800Eh, RSPI1.SPND A006 840Eh, RSPI2.SPND A006 880Eh, RSPI3.SPND A006 8C0Eh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	SPNDL[2:0]		
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SPNDL[2:0]	RSPI Next-Access Delay Setting	b2 b0 0 0 0: 1 RSPCK + 2 SERICLK 0 0 1: 2 RSPCK + 2 SERICLK 0 1 0: 3 RSPCK + 2 SERICLK 0 1 1: 4 RSPCK + 2 SERICLK 1 0 0: 5 RSPCK + 2 SERICLK 1 0 1: 6 RSPCK + 2 SERICLK 1 1 0: 7 RSPCK + 2 SERICLK 1 1 1: 8 RSPCK + 2 SERICLK	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPNDL[2:0] Bits (RSPI Next-Access Delay Setting)

The SPNDL[2:0] bits set a next-access delay when the SPCMDm.SPNDEN bit is 1.

When using the RSPI in slave mode, set the SPNDL[2:0] bits to 000b.

36.2.13 RSPI Control Register 2 (SPCR2)

The SPCR2 register controls the settings for operation of the RSPI.
Changing the value of SPPE, SPOE, or SCKASE bit in the SPCR2 register is prohibited while the setting of the SPCR.SPE bit is 1.

Address(es): RSPI0.SPCR2 A006 800Fh, RSPI1.SPCR2 A006 840Fh, RSPI2.SPCR2 A006 880Fh, RSPI3.SPCR2 A006 8C0Fh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	SCKASE	PTE	SPIIE	SPOE	SPPE
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPPE	Parity Enable	0: Does not add the parity bit to transmit data and does not check the parity bit of receive data 1: Adds the parity bit to transmit data and checks the parity bit of receive data (when SPCR.TXMD = 0) Adds the parity bit to transmit data but does not check the parity bit of receive data (when SPCR.TXMD = 1)	R/W
b1	SPOE	Parity Mode	0: Selects even parity for use in transmission and reception 1: Selects odd parity for use in transmission and reception	R/W
b2	SPIIE	RSPI Idle Interrupt Enable	0: Disables the generation of idle interrupt requests 1: Enables the generation of idle interrupt requests	R/W
b3	PTE	Parity Self-Testing	0: Disables the self-diagnosis function of the parity circuit 1: Enables the self-diagnosis function of the parity circuit	R/W
b4	SCKASE	RSPCK Auto-Stop Function Enable	0: Disables the RSPCK auto-stop function 1: Enables the RSPCK auto-stop function	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SPPE Bit (Parity Enable)

The SPPE bit enables or disables the parity function.
The parity bit is added to transmit data and parity checking is performed for receive data when the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1.
The parity bit is added to transmit data but parity checking is not performed for receive data when the SPCR.TXMD bit is 1 and the SPCR2.SPPE bit is 1.

SPOE Bit (Parity Mode)

The SPOE bit specifies odd or even parity.
When even parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is even. Similarly, when odd parity is set, parity bit addition is performed so that the total number of 1-bits in the transmit/receive character plus the parity bit is odd.
The SPOE bit is valid only when the SPPE bit is 1.

SPIIE Bit (RSPI Idle Interrupt Enable)

The SPIIE bit enables or disables the generation of RSPI idle interrupt requests when the RSPI being in the idle state is detected and the SPSR.IDLNF flag is set to 0.

PTE Bit (Parity Self-Testing)

The PTE bit enables the self-diagnosis function of the parity circuit in order to check whether the parity function is operating correctly.

SCKASE Bit (RSPCK Auto-Stop Function Enable)

The SCKASE bit enables or disables the RSPCK auto-stop function. When this function is enabled, the RSPCK clock is stopped before an overrun error occurs when data is received in master mode. For details, see section 36.3.8.1, Overrun Error.

36.2.14 RSPI Command Registers 0 to 7 (SPCMD0 to SPCMD7)

SPCMDm registers control a transfer format for the RSPI in master mode. Each channel has eight RSPI command registers (m = 0 to 7).

Some of the bits in the SPCMD0 register is used to set a transfer format for the RSPI in slave mode. The RSPI in master mode refers to SPCMDm registers in sequence according to the settings in the SPSCR.SPSLN[2:0] bits, and executes the serial transfer that is set in respective SPCMDm registers.

SPCMDm registers should be set while the transmission buffers are empty (data for the next transfer is not set) and before setting of the data that are to be transmitted as a result of reference to the SPCMDm registers.

SPCMDm currently being referred to by the RSPI in master mode can be checked by means of the SPSSR.SPCP[2:0] bits. Writing to SPCMDm is prohibited while the SPCR.MSTR bit is 0 and the SPCR.SPE bit is 1.

Address(es): RSPI0.SPCMD0 A006 8010h, RSPI0.SPCMD1 A006 8012h, RSPI0.SPCMD2 A006 8014h, RSPI0.SPCMD3 A006 8016h, RSPI0.SPCMD4 A006 8018h, RSPI0.SPCMD5 A006 801Ah, RSPI0.SPCMD6 A006 801Ch, RSPI0.SPCMD7 A006 801Eh, RSPI1.SPCMD0 A006 8410h, RSPI1.SPCMD1 A006 8412h, RSPI1.SPCMD2 A006 8414h, RSPI1.SPCMD3 A006 8416h, RSPI1.SPCMD4 A006 8418h, RSPI1.SPCMD5 A006 841Ah, RSPI1.SPCMD6 A006 841Ch, RSPI1.SPCMD7 A006 841Eh, RSPI2.SPCMD0 A006 8810h, RSPI2.SPCMD1 A006 8812h, RSPI2.SPCMD2 A006 8814h, RSPI2.SPCMD3 A006 8816h, RSPI2.SPCMD4 A006 8818h, RSPI2.SPCMD5 A006 881Ah, RSPI2.SPCMD6 A006 881Ch, RSPI2.SPCMD7 A006 881Eh, RSPI3.SPCMD0 A006 8C10h, RSPI3.SPCMD1 A006 8C12h, RSPI3.SPCMD2 A006 8C14h, RSPI3.SPCMD3 A006 8C16h, RSPI3.SPCMD4 A006 8C18h, RSPI3.SPCMD5 A006 8C1Ah, RSPI3.SPCMD6 A006 8C1Ch, RSPI3.SPCMD7 A006 8C1Eh

b14	SLNDEN	SSL Negation Delay Setting Enable	0: An SSL negation delay of 1 RSPCK 1: An SSL negation delay is equal to the setting of the RSPI slave select negation delay register (SSLND)	R/W
b15	SCKDEN	RSPCK Delay Setting Enable	0: An RSPCK delay of 1 RSPCK 1: An RSPCK delay is equal to the setting of the RSPI clock delay register (SPCKD)	R/W

CPHA Bit (RSPCK Phase Setting)

The CPHA bit sets an RSPCK phase of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK phase setting between the modules.

CPOL Bit (RSPCK Polarity Setting)

The CPOL bit sets an RSPCK polarity of the RSPI in master mode or slave mode. Data communications between RSPI modules require the same RSPCK polarity setting between the modules.

BRDV[1:0] Bits (Bit Rate Division Setting)

The BRDV[1:0] bits are used to determine the bit rate. A bit rate is determined by combinations of the settings in the BRDV[1:0] bits and SPBR (refer to section 36.2.8, RSPI Bit Rate Register (SPBR)). The settings in SPBR determine the base bit rate. The settings in the BRDV[1:0] bits are used to select a bit rate which is obtained by dividing the base bit rate by 1, 2, 4, or 8. In SPCMDm register, different BRDV[1:0] bit settings can be specified. This permits the execution of serial transfers at a different bit rate for each command (m = 0 to 7).

SSLy[2:0] Bits (SSL Signal Assertion Setting)

The SSLy[2:0] bits control the SSLyi signal assertion when the RSPI performs serial transfers in master mode.
Setting the SSLy[2:0] bits controls the assertion for the SSLyi signal. When an SSLyi signal is asserted, its polarity is determined by the set value in the corresponding SSLP. When the SSLy[2:0] bits are set to 000b in multi-master mode, serial transfers are performed with all the SSL signals in the negated state (as the SSLy0 pin acts as input).
When using the RSPI in slave mode, set the SSLy[2:0] bits to 000b.
(y = 0, 1, 2, 3 (for all channels); i = 0 to 3)

SSLKP Bit (SSL Signal Level Keeping)

When the RSPI in master mode performs a serial transfer, the SSLKP bit specifies whether the SSLyi signal level for the current command is to be kept or negated between the SSL negation timing associated with the current command and the SSL assertion timing associated with the next command.
Setting the SSLKP bit to 1 enables a burst transfer. For details, refer to section 36.3.10.1, (4) Burst Transfer.
When using the RSPI in slave mode, the SSLKP bit should be set to 0.
(y = 0, 1, 2, 3 (for all channels); i = 0 to 3)

SPB[3:0] Bits (RSPI Data Length Setting)

The SPB[3:0] bits set a transfer data length for the RSPI in master mode or slave mode.

LSBF Bit (RSPI LSB First)

The LSBF bit sets the data format of the RSPI in master mode or slave mode to MSB first or LSB first.

SPNDEN Bit (RSPI Next-Access Delay Enable)

The SPNDEN bit sets the period from the time the RSPI in master mode terminates a serial transfer and sets the SSLyi signal inactive until the RSPI enables the SSLyi signal assertion for the next access (next-access delay) (y = 0, 1, 2, 3 (for all channels); i = 0 to 3). If the SPNDEN bit is 0, the RSPI sets the next-access delay to 1 RSPCK + 2 SERICLK. If the SPNDEN bit is 1, the RSPI inserts a next-access delay in compliance with the SPND setting.
When using the RSPI in slave mode, the SPNDEN bit should be set to 0.

SLNDEN Bit (SSL Negation Delay Setting Enable)

The SLNDEN bit sets the period from the time the RSPI in master mode stops RSPCK oscillation until the RSPI sets the SSLyi signal inactive (SSL negation delay). If the SLNDEN bit is 0, the RSPI sets the SSL negation delay to 1 RSPCK. If the SLNDEN bit is 1, the RSPI negates the SSL signal at an SSL negation delay in compliance with the SSLND setting.
When using the RSPI in slave mode, the SLNDEN bit should be set to 0.

SCKDEN Bit (RSPCK Delay Setting Enable)

The SCKDEN bit sets the period from the point when the RSPI in master mode activates the SSLyi signal until the RSPCK starts oscillation (RSPI clock delay). If the SCKDEN bit is 0, the RSPI sets the RSPCK delay to 1 RSPCK. If the SCKDEN bit is 1, the RSPI starts the oscillation of RSPCK at an RSPCK delay in compliance with the SPCKD setting.
When using the RSPI in slave mode, the SCKDEN bit should be set to 0.

36.3 Operation

In this section, the serial transfer period means a period from the beginning of driving valid data to the fetching of the final valid data.

36.3.1 Overview of RSPI Operations

The RSPI is capable of synchronous serial transfers in slave mode (SPI operation), single-master mode (SPI operation), multi-master mode (SPI operation), slave mode (clock synchronous operation), and master mode (clock synchronous operation). A particular mode of the RSPI can be selected by using the MSTR, MODFEN, and SPMS bits in SPCR. Table 36.5 lists the relationship between RSPI modes and SPCR settings, and a description of each mode.

Table 36.5 Relationship between RSPI Modes and SPCR Settings and Description of Each Mode

Mode	Slave (SPI Operation)	Single-Master (SPI Operation)	Multi-Master (SPI Operation)	Slave (Clock Synchronous Operation)	Master (Clock Synchronous Operation)
MSTR bit setting	0	1	1	0	1
MODFEN bit setting	0 or 1	0	1	0	0
SPMS bit setting	0	0	0	1	1
RSPCKy signal	Input	Output	Output/Hi-Z	Input	Output
MOSIy signal	Input	Output	Output/Hi-Z	Input	Output
MISOy signal	Output/Hi-Z	Input	Input	Output	Input
SSLy0 signal	Input	Output	Input	Hi-Z*1	Hi-Z*1
SSLy1 to SSLy3 signals	Hi-Z*1	Output	Output/Hi-Z	Hi-Z*1	Hi-Z*1
SSL polarity modification function	Supported	Supported	Supported	—	—
Transfer rate	Up to SERICLK/8	Up to SERICLK/4	Up to SERICLK/4	Up to SERICLK/8	Up to SERICLK/4
Clock source	RSPCK input	On-chip baud rate generator	On-chip baud rate generator	RSPCK input	On-chip baud rate generator
Clock polarity	Two				
Clock phase	Two	Two	Two	One (CPHA = 1)	Two
First transfer bit	MSB/LSB				
Transfer data length	8 to 16, 20, 24, 32 bits				
Burst transfer	Possible (CPHA = 1)	Possible (CPHA = 0,1)	Possible (CPHA = 0,1)	—	—
RSPCK delay control	Not supported	Supported	Supported	Not supported	Supported
SSL negation delay control	Not supported	Supported	Supported	Not supported	Supported
Next-access delay control	Not supported	Supported	Supported	Not supported	Supported
Transfer activation method	SSL input active or RSPCK oscillation	Transmission buffer is written to at generation of a transmission buffer empty interrupt request	Transmission buffer is written to at generation of a transmission buffer empty interrupt request	RSPCK oscillation	Transmission buffer is written to at generation of a transmission buffer empty interrupt request
Sequence control	Not supported	Supported	Supported	Not supported	Supported
Transmission buffer empty detection	Supported				
Reception buffer full detection	Supported*2				
Overrun error detection	Supported*2	Supported*2, *4	Supported*2, *4	Supported*2	Supported*2
Parity error detection	Supported*2,*3				
Mode fault error detection	Supported (MODFEN = 1)	Not supported	Supported	Not supported	Not supported

Note 1. This function is not supported in this mode.
Note 2. When the SPCR.TXMD bit is 1, receiver buffer full detection, overrun error detection, and parity error detection are not performed.
Note 3. When the SPCR2.SPPE bit is 0, parity error detection is not performed.
Note 4. When the SPCR2.SCKASE bit is 1, overrun error detection does not proceed.
y = 0, 1, 2, 3 (for all channels)

36.3.2 Controlling RSPI Pins

According to the SPCR.MSTR, MODFEN, SPMS, and SPPCR.SPOM bits, the RSPI can switch pin states. Table 36.6 lists the relationship between pin states and bit settings. Setting the SPPCR.SPOM bit to 0 selects CMOS output; setting it to 1 selects open-drain output. The I/O port settings should follow this relationship.

Table 36.6 Relationship between Pin States and Bit Settings

		Pin State*2	
Mode	**Pin**	**SPOM = 0**	**SPOM = 1**
Single-master mode (SPI operation) (MSTR = 1, MODFEN = 0, SPMS = 0)	RSPCKy	CMOS output	Open-drain output
	SSLy0 to SSLy3	CMOS output	Open-drain output
	MOSIy	CMOS output	Open-drain output
	MISOy	Input	Input
Multi-master mode (SPI operation) (MSTR = 1, MODFEN = 1, SPMS = 0)	RSPCKy*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	SSLy0	Input	Input
	SSLy1 to SSLy3*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MOSIy*3	CMOS output/Hi-Z	Open-drain output/Hi-Z
	MISOy	Input	Input
Slave mode (SPI operation) (MSTR = 0, SPMS = 0)	RSPCKy	Input	Input
	SSLy0	Input	Input
	SSLy1 to SSLy3*5	Hi-Z*1	Hi-Z*1
	MOSIy	Input	Input
	MISOy*4	CMOS output/Hi-Z	Open-drain output/Hi-Z
Master mode (Clock synchronous operation) (MSTR = 1, MODFEN = 0, SPMS = 1)	RSPCKy	CMOS output	Open-drain output
	SSLy0 to SSLy3*5	Hi-Z*1	Hi-Z*1
	MOSIy	CMOS output	Open-drain output
	MISOy	Input	Input
Slave mode (Clock synchronous operation) (MSTR = 0, SPMS = 1)	RSPCKy	Input	Input
	SSLy0 to SSLy3*5	Hi-Z*1	Hi-Z*1
	MOSIy	Input	Input
	MISOy	CMOS output	Open-drain output

Note 1. This function is not supported in this mode.
Note 2. RSPI settings are not reflected in the multiplex pins for which the RSPI function is not selected.
Note 3. When SSLy0 is at the active level, the pin state is Hi-Z.
Note 4. When SSLy0 is at the non-active level or the SPCR.SPE bit is 0, the pin state is Hi-Z.
Note 5. These pins are available for use as I/O port pins.
y = 0, 1, 2, 3 (for all channels)

The RSPI in single-master mode (SPI operation) or multi-master mode (SPI operation) determines MOSI signal values during the SSL negation period (including the SSL retention period during a burst transfer) according to MOIFE and MOIFV bit settings in SPPCR, as listed in Table 36.7.

Table 36.7 MOSI Signal Value Determination during SSL Negation Period

MOIFE Bit	MOIFV Bit	MOSIy Signal Value during SSL Negation Period
0	0, 1	Final data from previous transfer
1	0	Always low
1	1	Always high

Note: During the period of SSL negation, the RSPI function must be enabled (i.e. SPCR.SPE bit = 1) for control over the levels of the MOSIy signals.

36.3.3 RSPI System Configuration Examples

36.3.3.1 Single Master/Single Slave (with This LSI Acting as Master)

Figure 36.5 shows a single-master/single-slave RSPI system configuration example when this LSI is used as a master. In the single-master/single-slave configuration, the SSLy0 to SSLy3 output of this LSI (master) are not used. The SSL input of the SPI slave is fixed to the low level, and the SPI slave is always maintained in a select state.*1
This LSI (master) always drives RSPCKy and MOSIy. The SPI slave always drives the MISO.
(y = 0, 1, 2, 3 (for all channels))

Note 1. In the transfer format corresponding to the case where the SPCMDm.CPHA bit is 0, there are slave devices for which the SSL signal cannot be fixed to the active level. In situations where the SSL signal cannot be fixed, the SSLyi output of this LSI should be connected to the SSL input of the slave device.

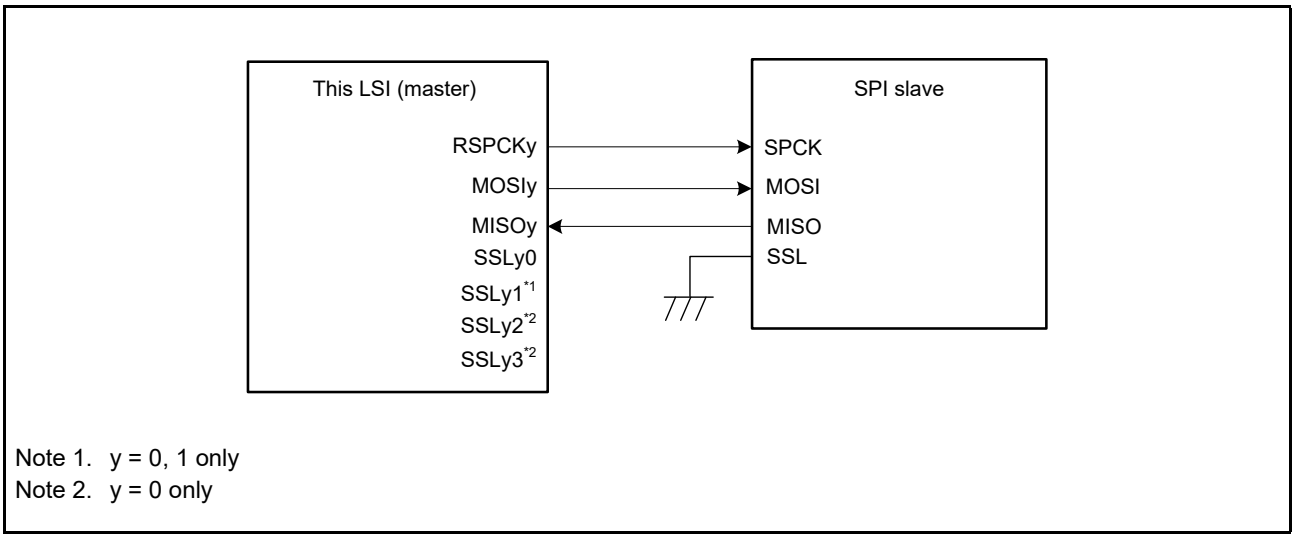

Figure 36.5 Single-Master/Single-Slave Configuration Example (This LSI = Master)

36.3.3.2 Single Master/Single Slave (with This LSI Acting as Slave)

Figure 36.6 shows a single-master/single-slave RSPI system configuration example when this LSI is used as a slave. When this LSI is to operate as a slave, the SSLy0 pin is used as SSL input. The SPI master always drives the RSPCK and MOSI. This LSI (slave) always drives the MISOy.*1

In the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, the SSLy0 input of this LSI (slave) is fixed to the low level, this LSI (slave) is always maintained in a select state, and in this manner it is possible to execute serial transfer (Figure 36.7).

(y = 0, 1, 2, 3 (for all channels))

Note 1. When SSLy0 is at the non-active level, the pin state is Hi-Z.

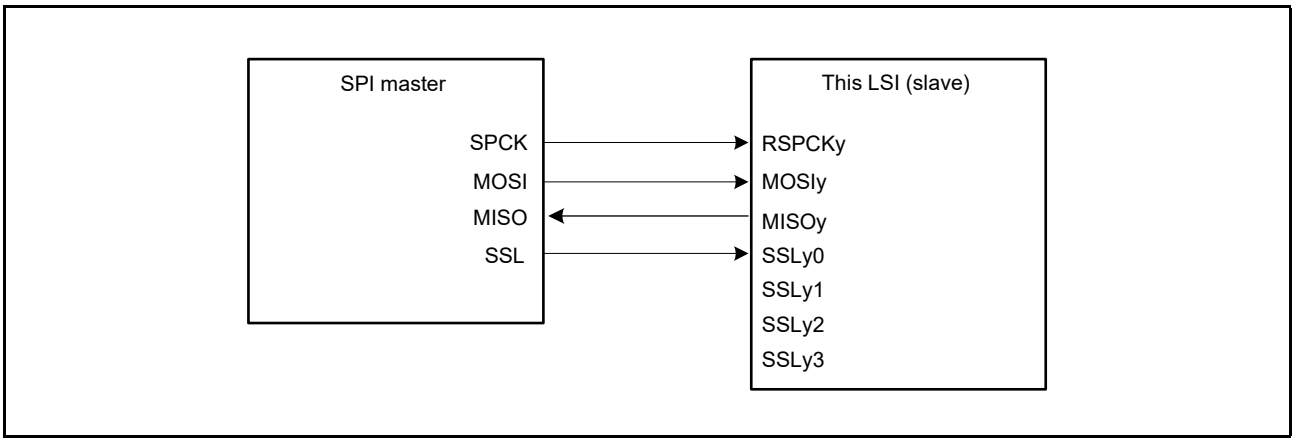

Figure 36.6 Single-Master/Single-Slave Configuration Example (This LSI = Slave, CPHA = 0)

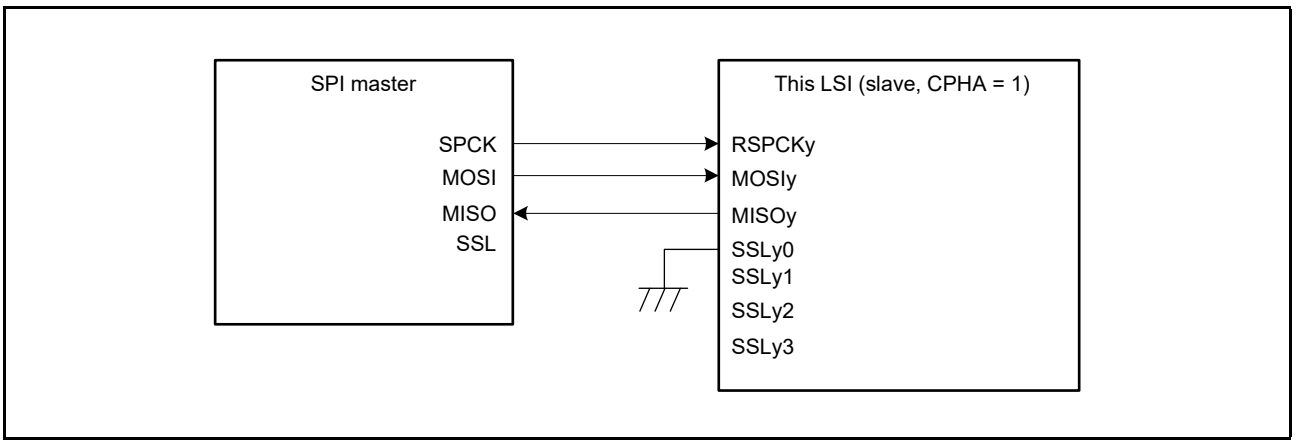

Figure 36.7 Single-Master/Single-Slave Configuration Example (This LSI = Slave, CPHA = 1)

36.3.3.3 Single Master/Multi-Slave (with This LSI Acting as Master)

Figure 36.8 shows a single-master/multi-slave RSPI system configuration example when this LSI is used as a master. In the example of Figure 36.8, the RSPI system is comprised of this LSI (master) and four slaves (SPI slave 0 to SPI slave 3).

The RSPCKy and MOSIy outputs of this LSI (master) are connected to the RSPCK and MOSI inputs of SPI slave 0 to SPI slave 3. The MISO outputs of SPI slave 0 to SPI slave 3 are all connected to the MISOy input of this LSI (master). SSLy0 to SSLy3 outputs of this LSI (master) are connected to the SSL inputs of SPI slave 0 to SPI slave 3, respectively. This LSI (master) always drives RSPCK, MOSI, and SSLy0 to SSLy3. Of the SPI slave 0 to SPI slave 3, the slave that receives low-level input into the SSL input drives MISO.

(y = 0, 1, 2, 3 (for all channels))

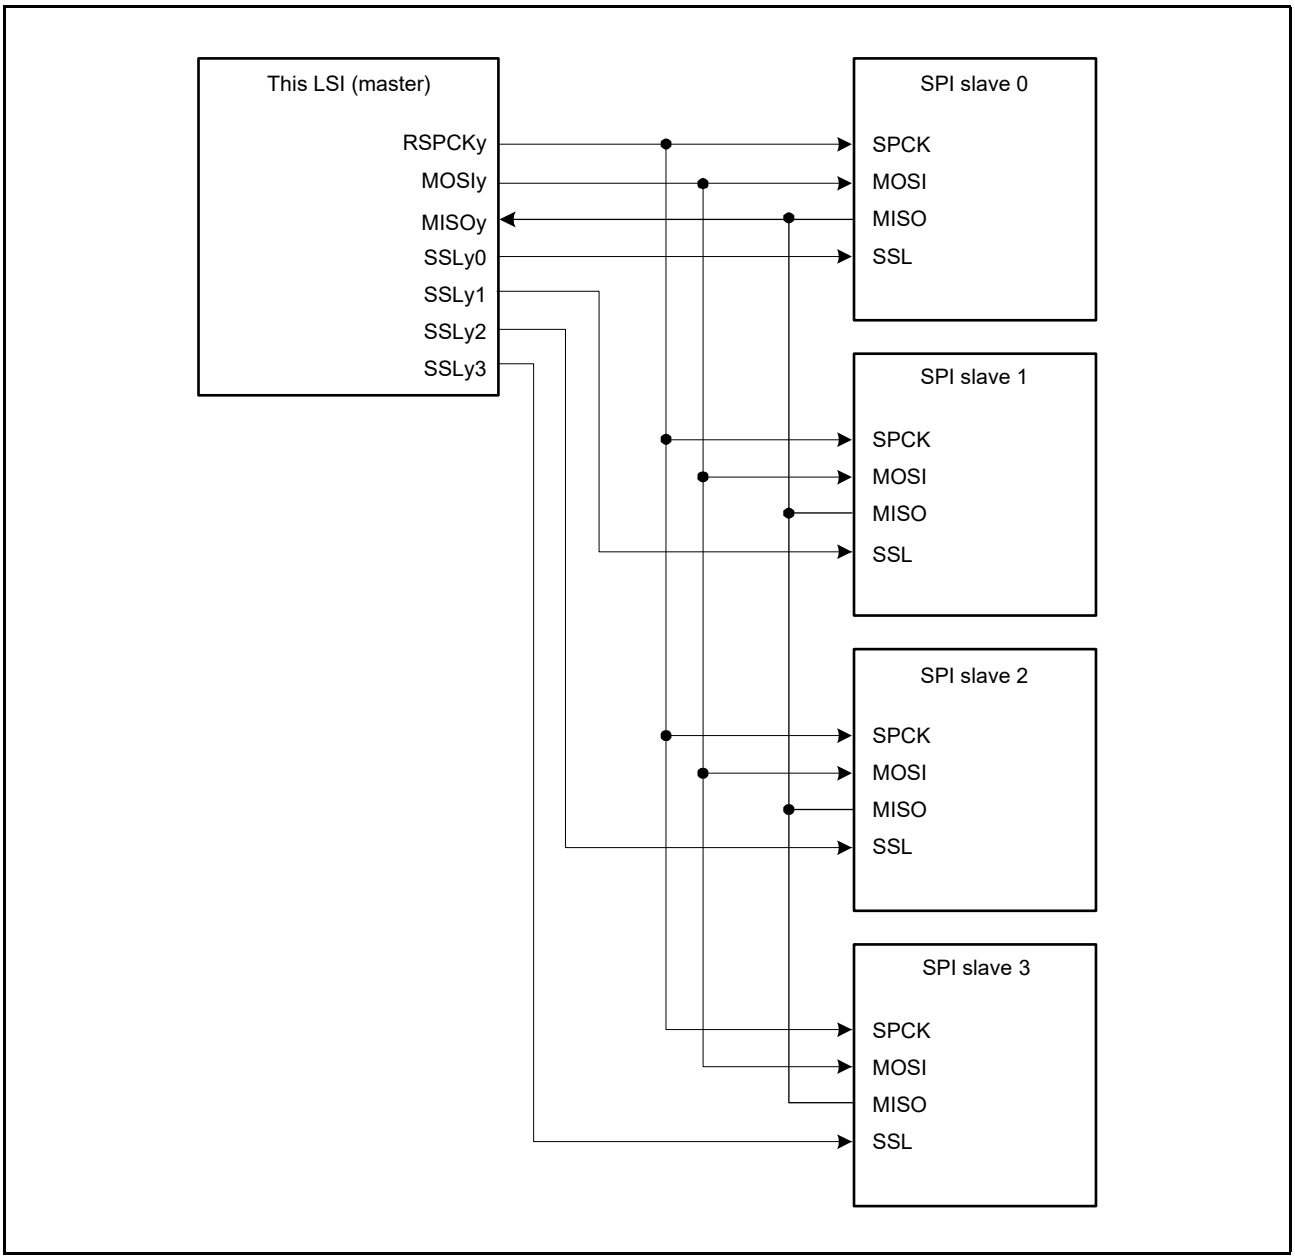

Figure 36.8 Single-Master/Multi-Slave Configuration Example (This LSI = Master)

36.3.3.4 Single Master/Multi-Slave (with This LSI Acting as Slave)

Figure 36.9 shows a single-master/multi-slave RSPI system configuration example when this LSI is used as a slave. In the example of Figure 36.9, the RSPI system is comprised of an SPI master and two LSIs (slave X and slave Y).
The SPCK and MOSI outputs of the SPI master are connected to the RSPCKy and MOSIy inputs of the LSIs (slave X and slave Y). The MISOy outputs of the LSIs (slave X and slave Y) are all connected to the MISO input of the SPI master. SSLX and SSLY outputs of the SPI master are connected to the SSLy0 inputs of the LSIs (slave X and slave Y), respectively.
The SPI master always drives SPCK, MOSI, SSLX, and SSLY. Of the LSIs (slave X and slave Y), the slave that receives low-level input into the SSLy0 input drives MISOy.
(y = 0, 1, 2, 3 (for all channels))

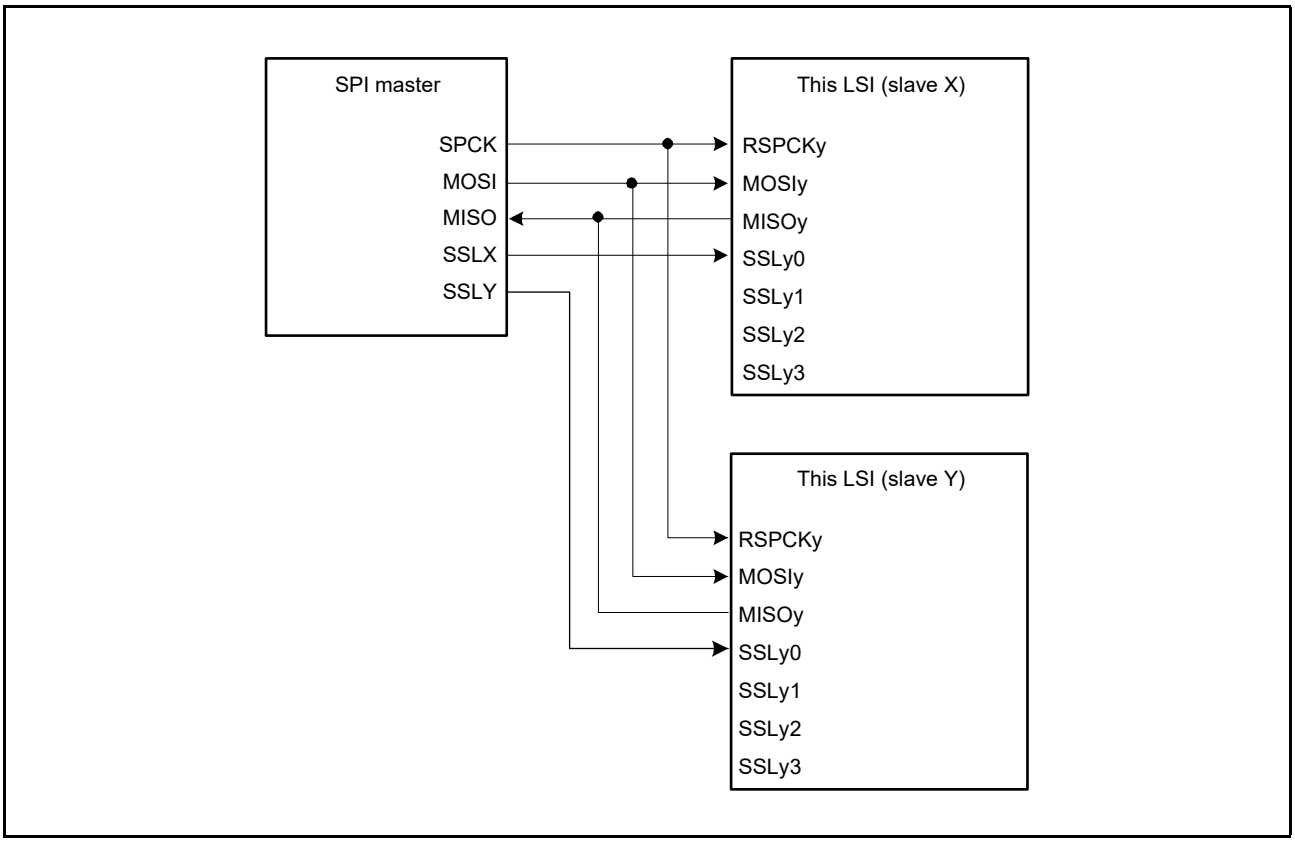

Figure 36.9 Single-Master/Multi-Slave Configuration Example (This LSI = Slave)

36.3.3.5 Multi-Master/Multi-Slave (with This LSI Acting as Master)

Figure 36.10 shows a multi-master/multi-slave RSPI system configuration example when this LSI is used as a master. In the example of Figure 36.10, the RSPI system is comprised of two LSIs (master X and master Y) and two SPI slaves (SPI slave 1 and SPI slave 2).

The RSPCKy and MOSIy outputs of the LSIs (master X and master Y) are connected to the RSPCK and MOSI inputs of SPI slaves 1 and 2. The MISO outputs of SPI slaves 1 and 2 are connected to the MISOy inputs of the LSIs (master X and master Y). Any generic port Y output from this LSI (master X) is connected to the SSLy0 input of this LSI (master Y). Any generic port X output of this LSI (master Y) is connected to the SSLy0 input of this LSI (master X). The SSLy1 and SSLy2 outputs of the LSIs (master X and master Y) are connected to the SSL inputs of the SPI slaves 1 and 2. In this configuration example, since the system can be comprised solely of SSLy0 input, and SSLy1 and SSLy2 outputs for slave connections, the SSLy3 output of this LSI is not required.

This LSI drives RSPCKy, MOSIy, SSLy1, and SSLy2 when the SSLy0 input level is high. When the SSLy0 input level is low, this LSI detects a mode fault error, sets RSPCKy, MOSIy, SSLy1, and SSLy2 to Hi-Z, and releases the RSPI bus right to the other master. Of the SPI slaves 1 and 2, the slave that receives low-level input into the SSL input drives MISO.

(y = 0, 1, 2, 3 (for all channels))

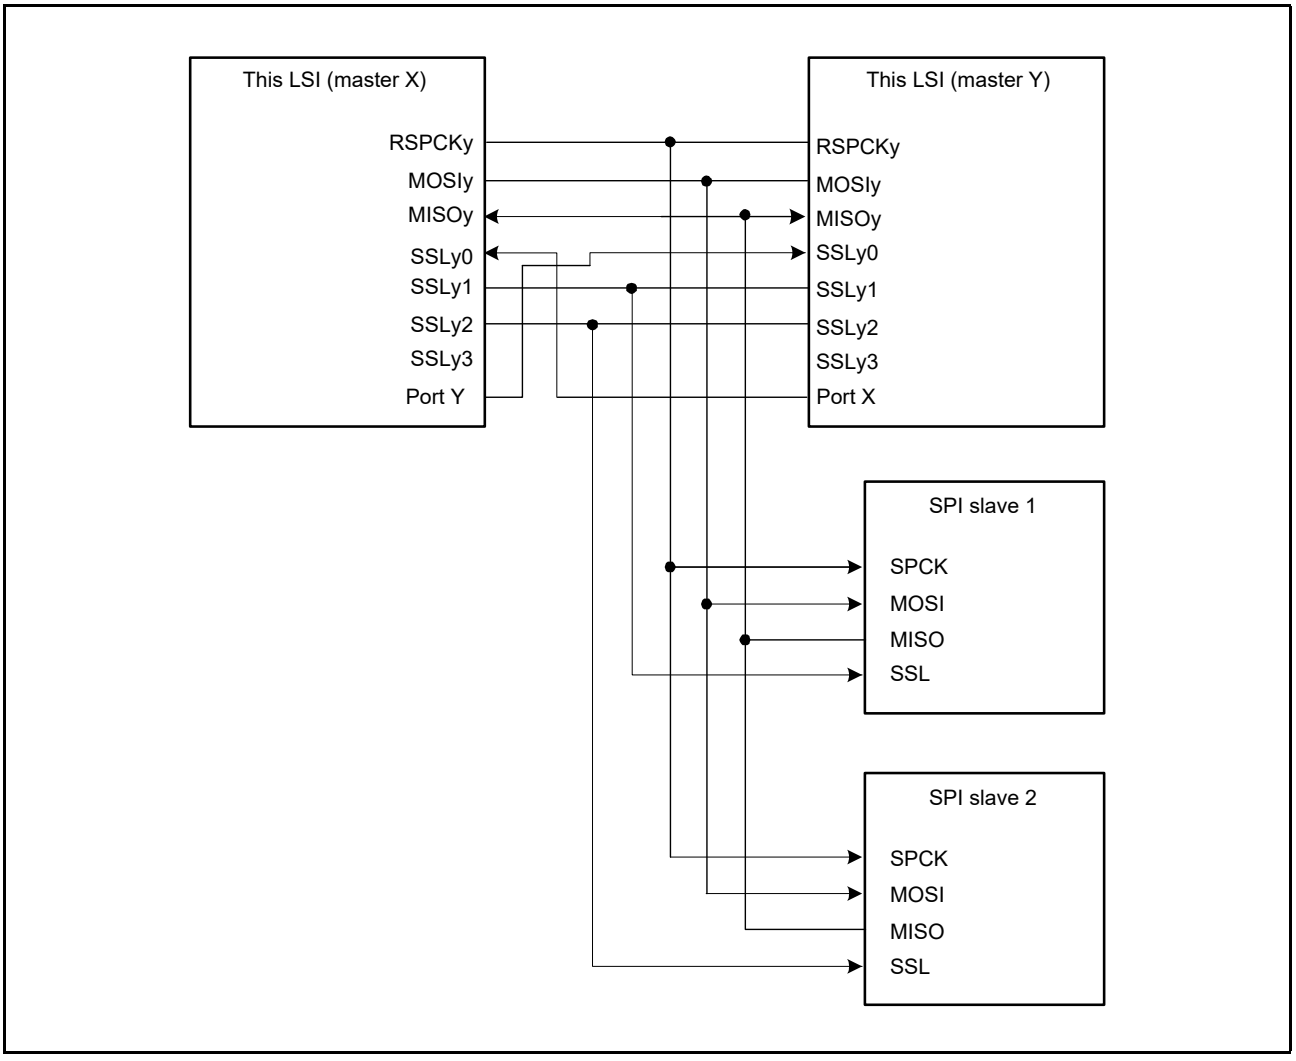

Figure 36.10 Multi-Master/Multi-Slave Configuration Example (This LSI = Master)

36.3.3.6 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This LSI Acting as Master)

Figure 36.11 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this LSI is used as a master. In the master (clock synchronous operation)/slave (clock synchronous operation) configuration, SSLy0 to SSLy3 of this LSI (master) are not used.
This LSI (master) always drives the RSPCKy and MOSIy. The SPI slave always drives the MISO.
(y = 0, 1, 2, 3 (for all channels))

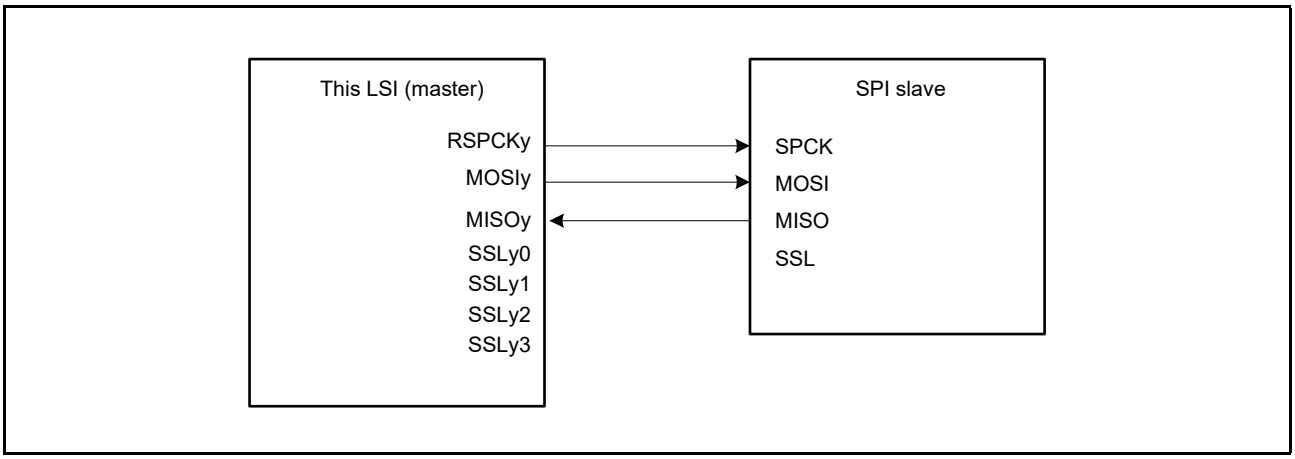

Figure 36.11 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This LSI = Master)

36.3.3.7 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) (with This LSI Acting as Slave)

Figure 36.12 shows a master (clock synchronous operation)/slave (clock synchronous operation) RSPI system configuration example when this LSI is used as a slave. When this LSI is to operate as a slave (clock synchronous operation), this LSI (slave) always drives the MISOy and the SPI master always drives the SPCK and MOSI. In addition, SSLy0 to SSLy3 of this LSI (slave) are not used.
Only in the single-slave configuration in which the SPCMDm.CPHA bit is set to 1, this LSI (slave) can execute serial transfer.
(y = 0, 1, 2, 3 (for all channels))

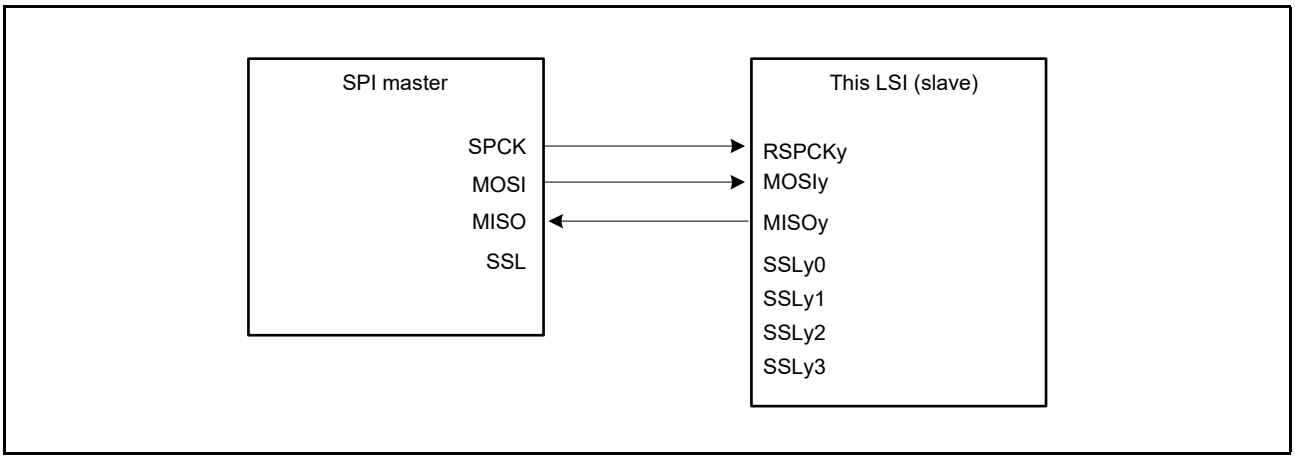

Figure 36.12 Master (Clock Synchronous Operation)/Slave (Clock Synchronous Operation) Configuration Example (This LSI = Slave, CPHA = 1)

36.3.4 Data Format

The RSPI's data format depends on the settings in RSPI command register m (SPCMDm) (m = 0 to 7) and the parity enable bit of RSPI control register 2 (SPCR2.SPPE). Regardless of whether the MSB or LSB is first, the RSPI treats the range from the LSB bit of the RSPI data register (SPDR) to the selected data length as transfer data.
The format of one frame of data before or after transfer is shown below.

(a) With Parity Disabled

When parity is disabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[3:0]).

(b) With Parity Enabled

When parity is enabled, transmission or reception of data proceeds with the length in bits selected in the RSPI data length setting bits in RSPI command register m (SPCMDm.SPB[3:0]). In this case, however, the last bit is a parity bit.

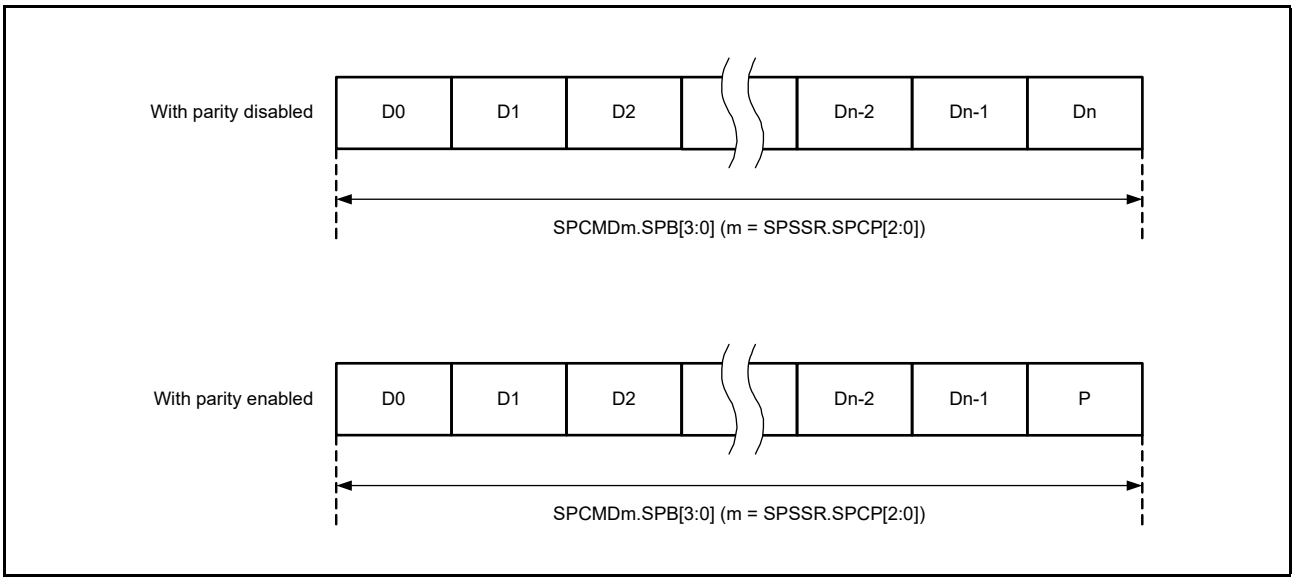

Figure 36.13 Outline of the Data Format (with Parity Disabled/Enabled)

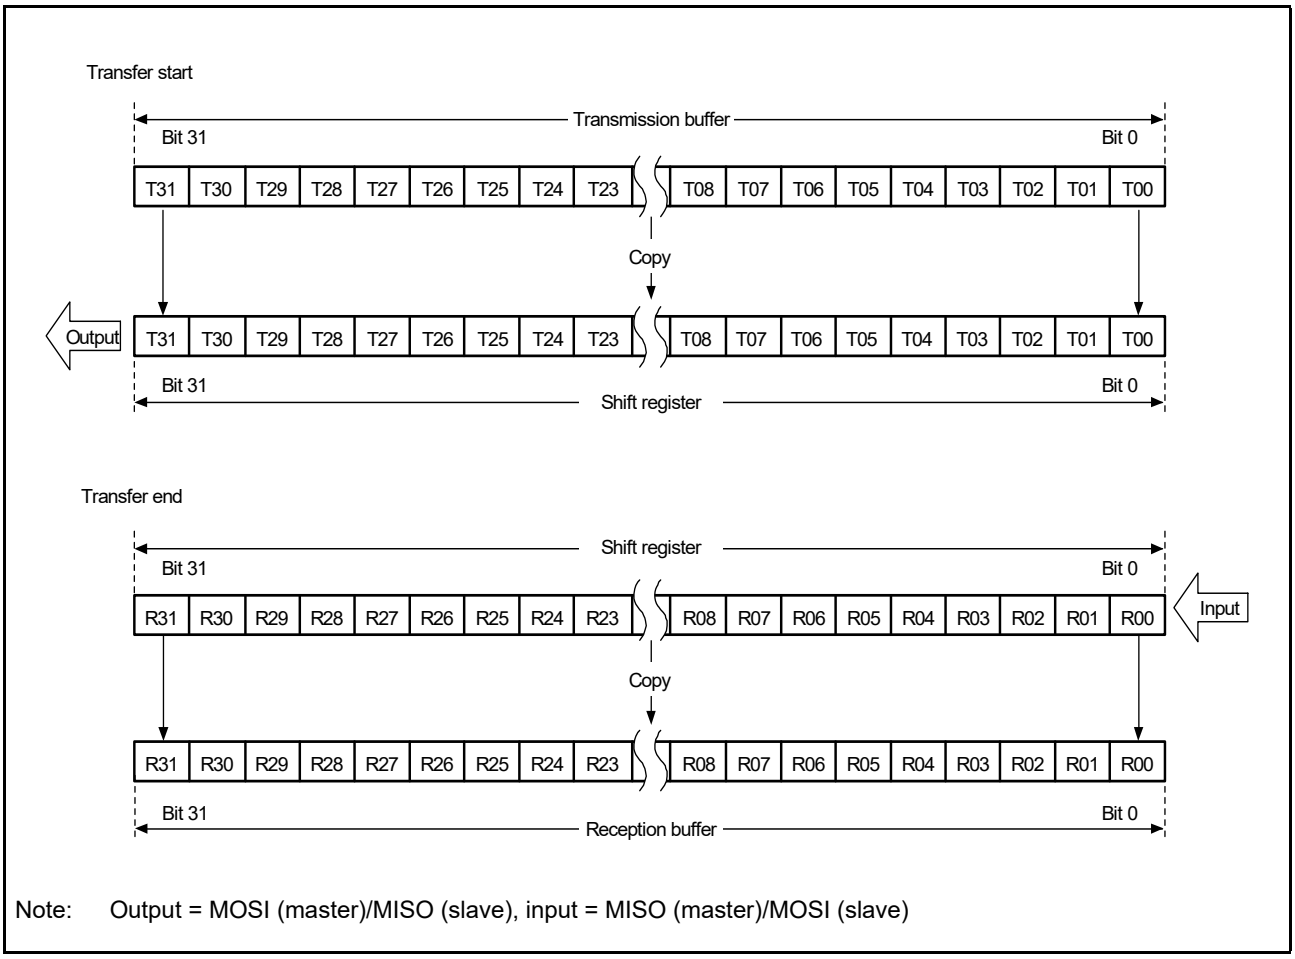
36.3.4.1 When Parity is Disabled (SPCR2.SPPE = 0)

When parity is disabled, data for transmission are copied to the shift register with no prior processing. A description of the connection between the RSPI data register (SPDR) and the shift register in terms of the combination of MSB or LSB first and data length is given below.

(1) MSB First Transfer (32-Bit Data)

Figure 36.14 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, bits T31 to T00 from the current stage of the transmission buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T31, through T30, and so on to T00.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

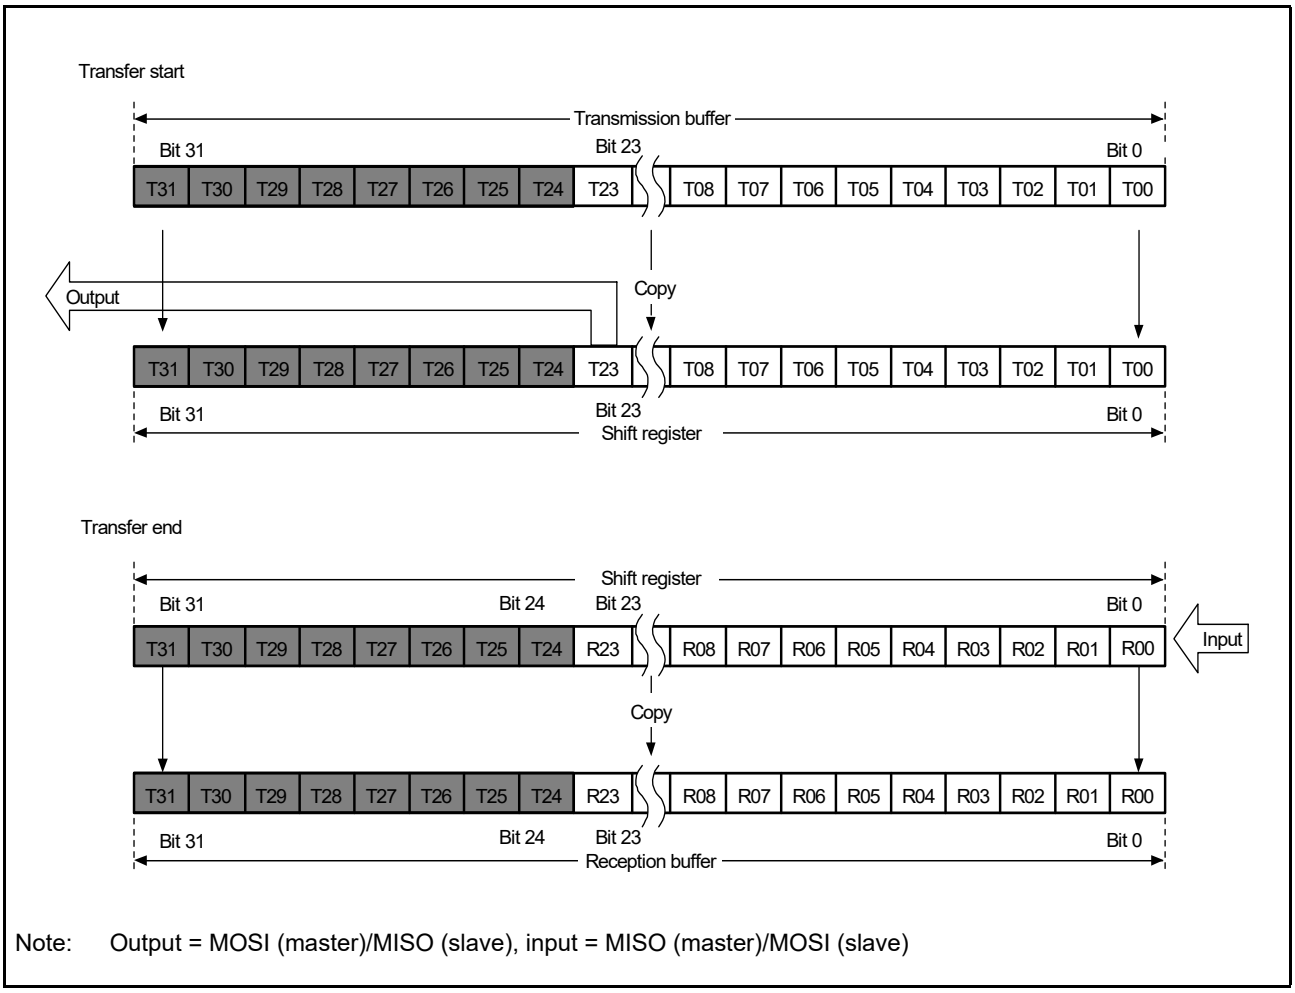
Figure 36.14 MSB First Transfer (32-Bit Data, Parity Disabled)

(2) MSB First Transfer (24-Bit Data)

Figure 36.15 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmission buffer are copied to the shift register. Data for transmission are shifted out from the shift register in order from T23, through T22, and so on to T00.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to R00 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer. At this time, the higher-order 8 bits of the transmission buffer are stored in the higher-order 8 bits of the reception buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the reception buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

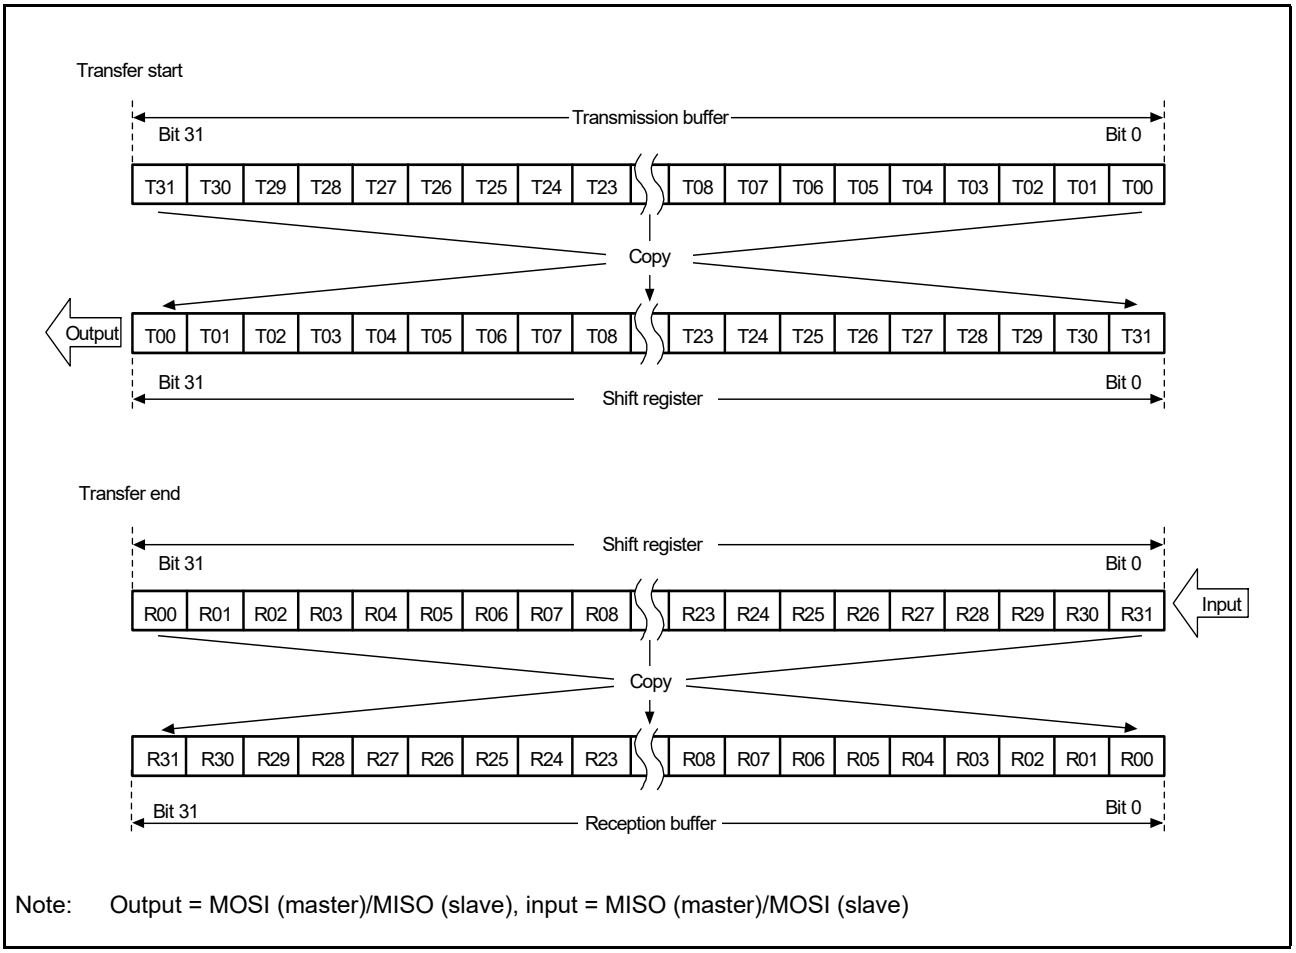
Figure 36.15 MSB First Transfer (24-Bit Data, Parity Disabled)

(3) LSB First Transfer (32-Bit Data)

Figure 36.16 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, bits T31 to T00 from the current stage of the transmission buffer are reordered bit by bit to obtain the order T00 to T31 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T31.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to R31 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.16 LSB First Transfer (32-Bit Data, Parity Disabled)

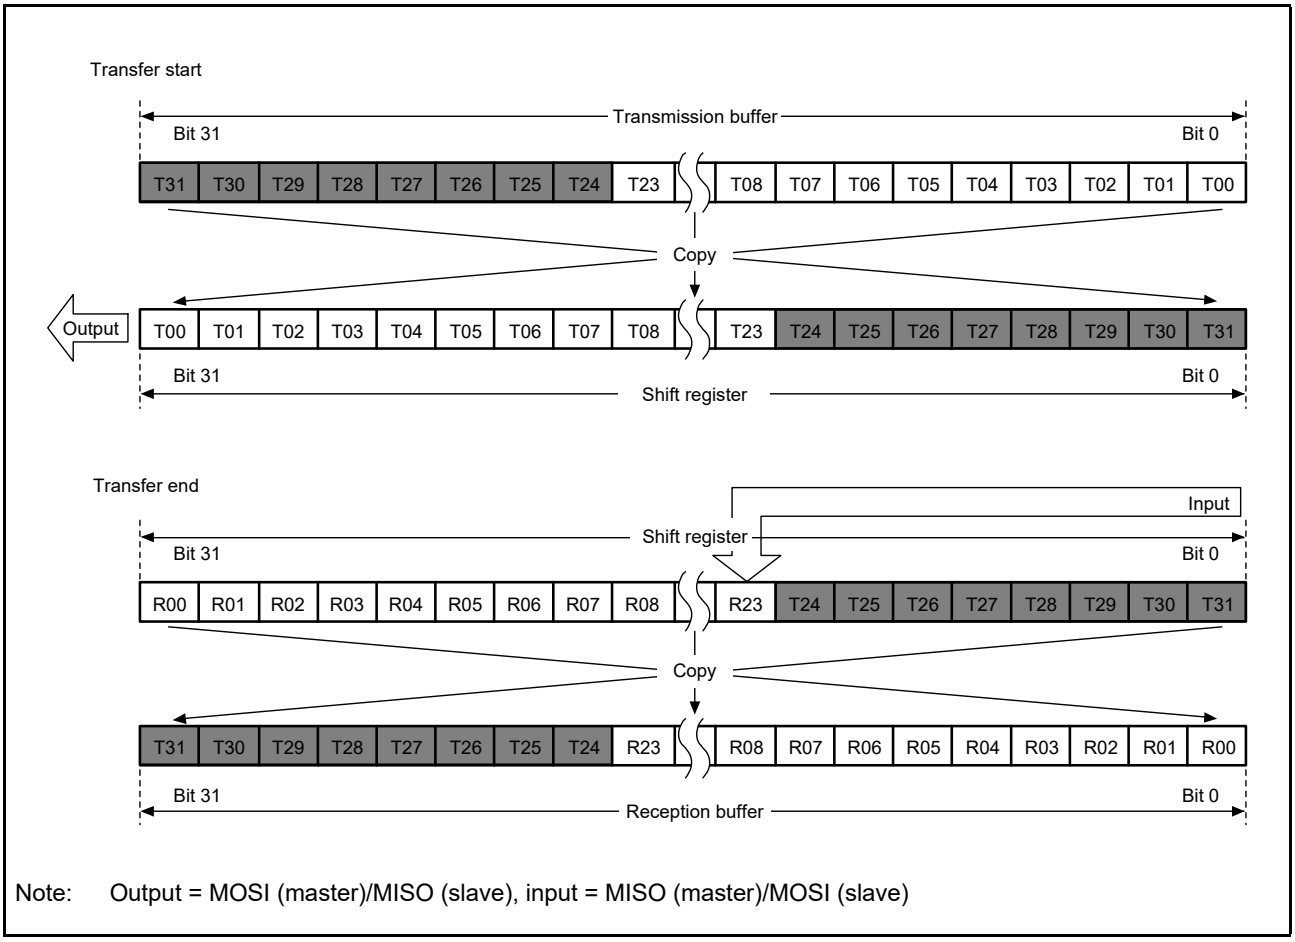
(4) LSB First Transfer (24-Bit Data)

Figure 36.17 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity disabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.

In transmission, the lower-order 24 bits (T23 to T00) from the current stage of the transmission buffer are reordered bit by bit to obtain the order T00 to T23 for copying to the shift register. Data for transmission are shifted out from the shift register in order from T00, through T01, and so on to T23.

In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to R23 have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer.

At this time, the higher-order 8 bits of the transmission buffer are stored in the higher-order 8 bits of the reception buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the reception buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

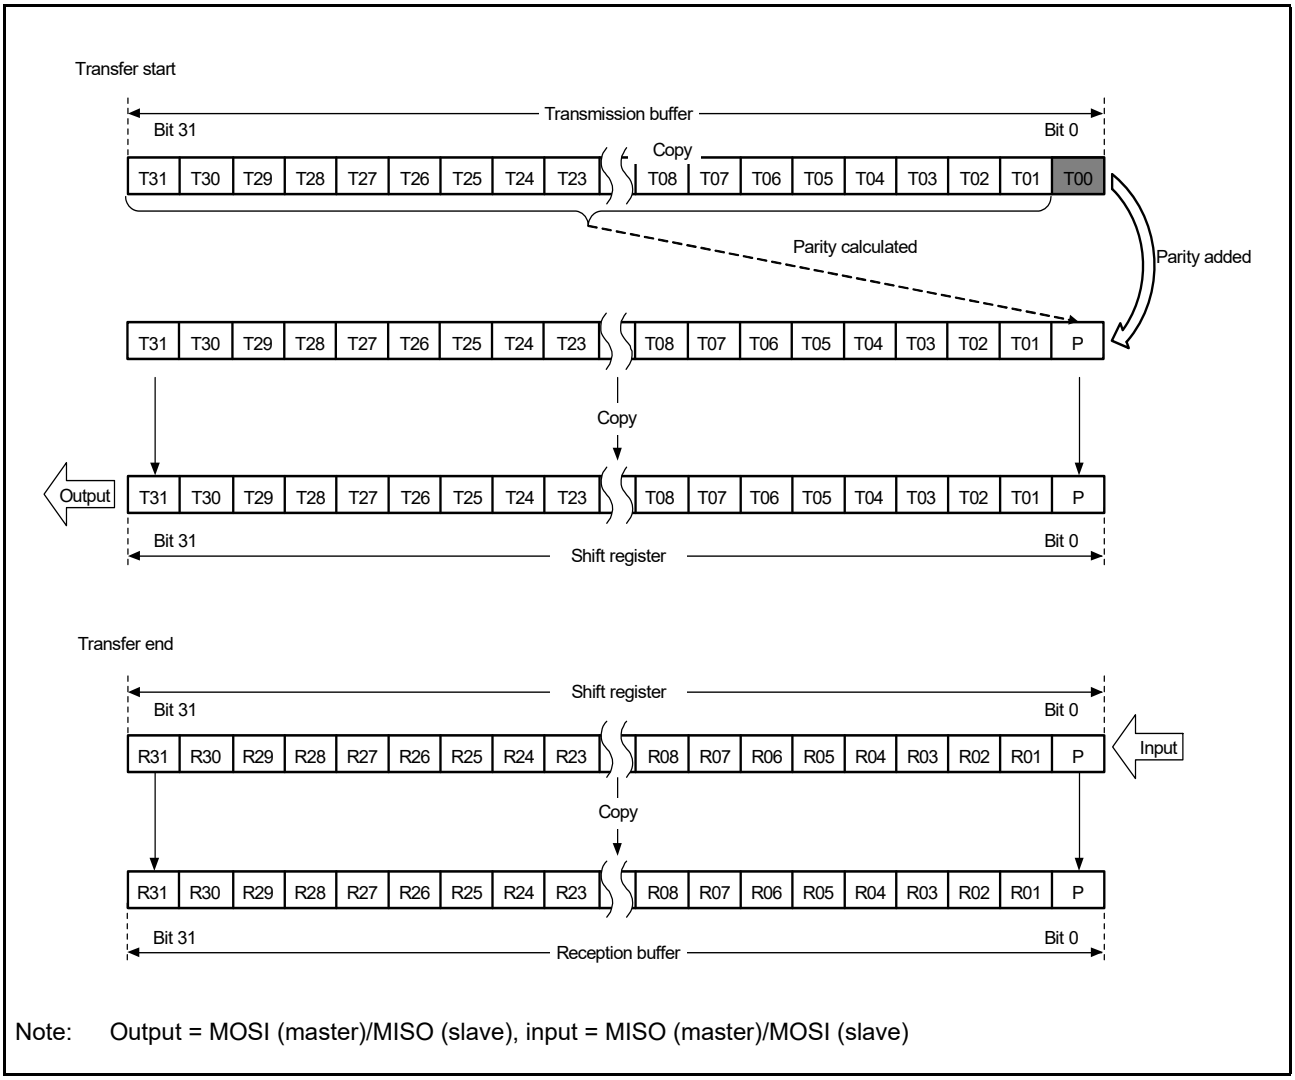
Figure 36.17 LSB First Transfer (24-Bit Data, Parity Disabled)

36.3.4.2 When Parity is Enabled (SPCR2.SPPE = 1)

When parity is enabled, the lowest-order bit of the data for transmission becomes a parity bit. Hardware calculates the value of the parity bit.

(1) MSB First Transfer (32-Bit Data)

Figure 36.18 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T31 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T31, T30, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R31 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer. On copying of data to the shift register, the data from R31 to P are checked by judging the parity.

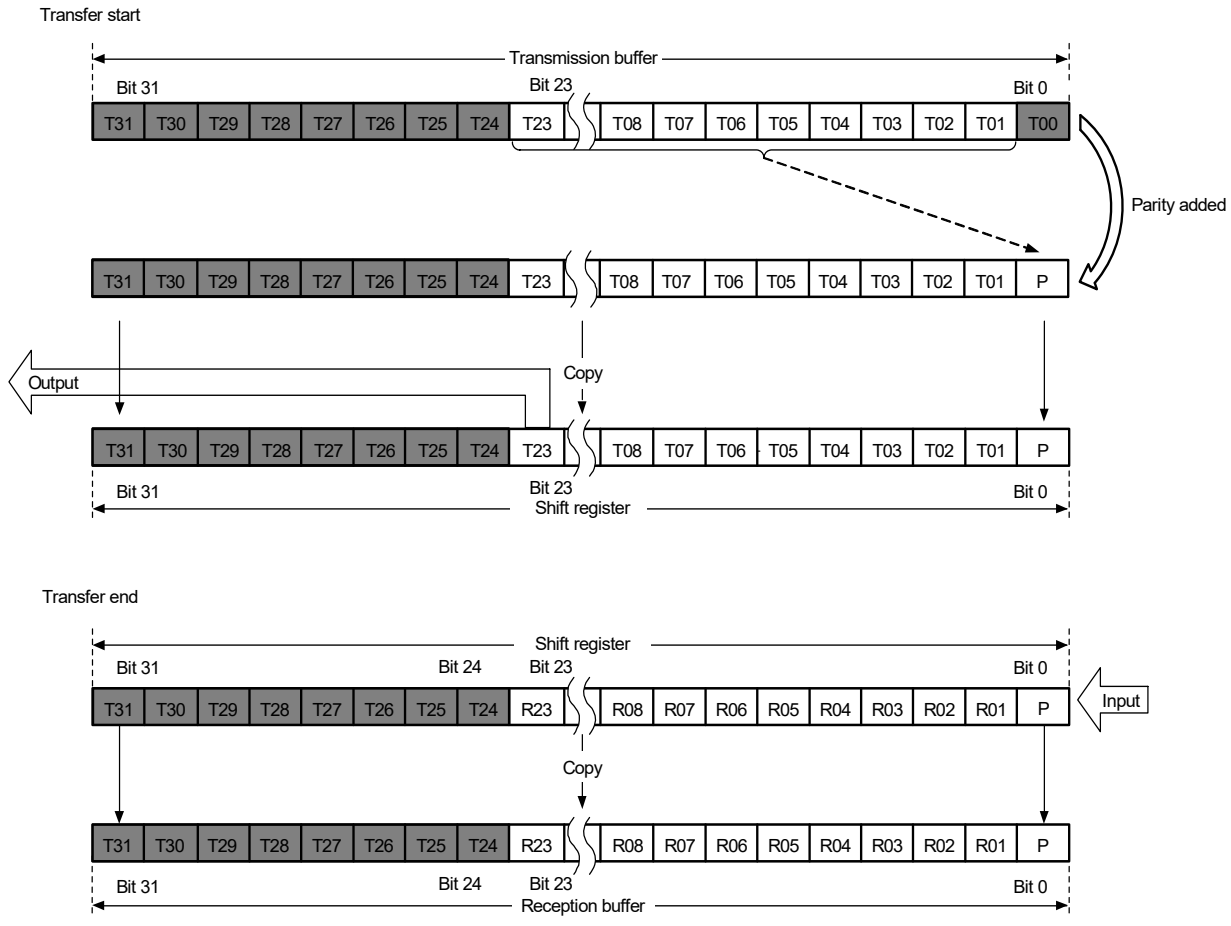


Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.18 MSB First Transfer (32-Bit Data, Parity Enabled)

(2) MSB First Transfer (24-Bit Data)

Figure 36.19 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and MSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T23 to T01. This replaces the final bit, T00, and the whole is copied to the shift register. Data are transmitted in the order T23, T22, …, T01, and P.
In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R23 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer. On copying of data to the shift register, the data from R23 to P are checked by judging the parity. At this time, the higher-order 8 bits of the transmission buffer are stored in the higher-order 8 bits of the reception buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the reception buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

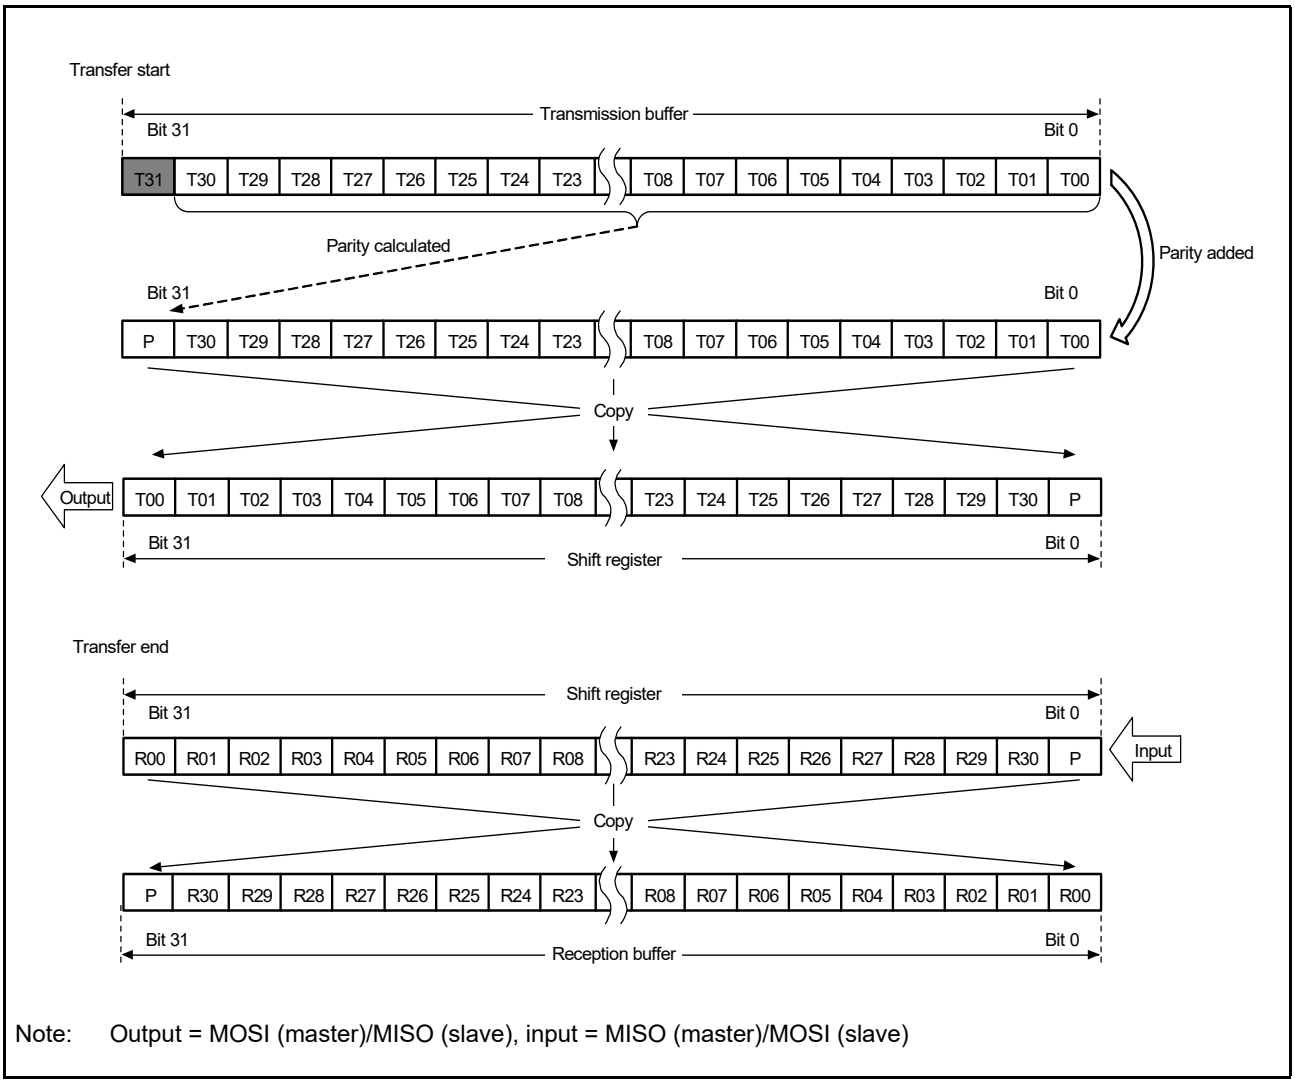
Figure 36.19 MSB First Transfer (24-Bit Data, Parity Enabled)

(3) LSB First Transfer (32-Bit Data)

Figure 36.20 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, an RSPI data length of 32 bits, and LSB first selected.

In transmission, the value of the parity bit (P) is calculated from bits T30 to T00. This replaces the final bit, T31, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T30, and P.

In reception, received data are shifted in bit by bit through bit 0 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity.

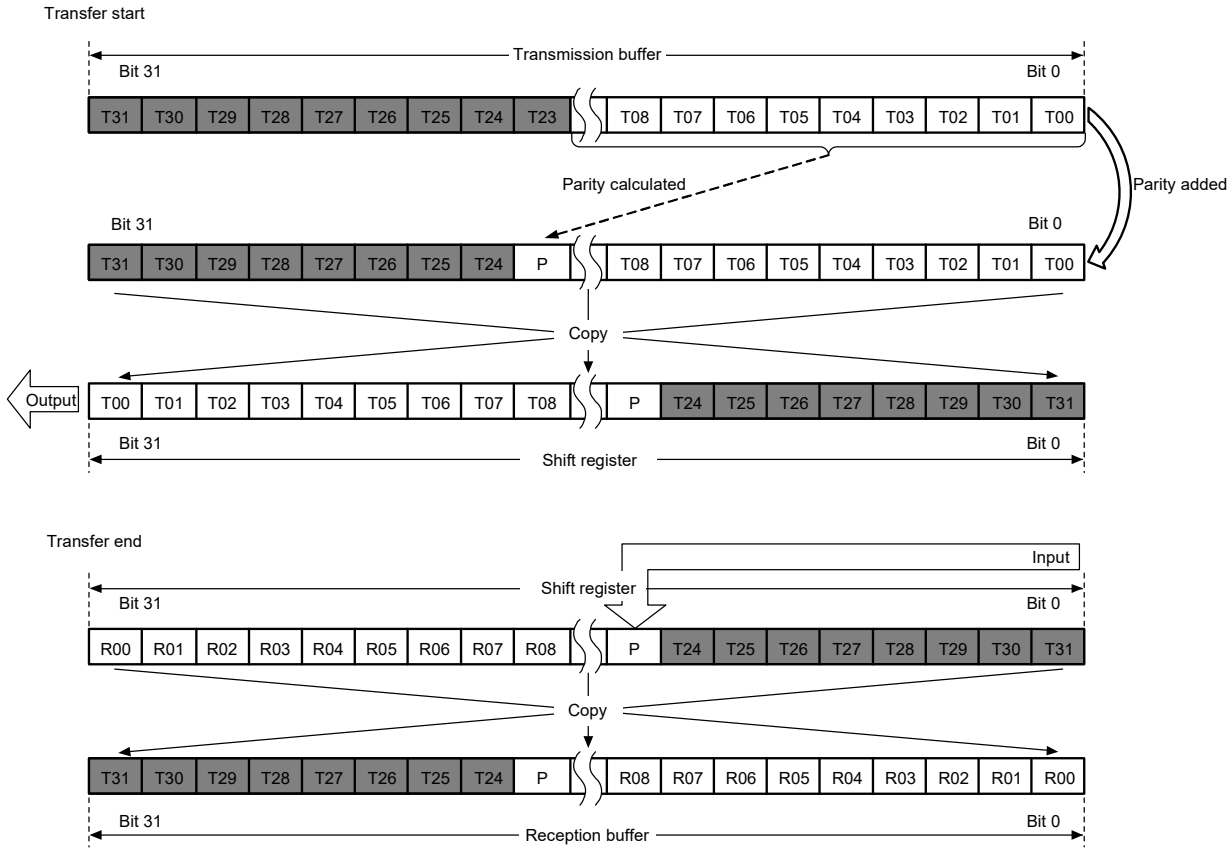


Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.20 LSB First Transfer (32-Bit Data, Parity Enabled)

(4) LSB First Transfer (24-Bit Data)

Figure 36.21 shows details of operations by the RSPI data register (SPDR) and the shift register in transfer with parity enabled, 24 bits as the RSPI data length for an example that is not 32 bits, and LSB first selected.
In transmission, the value of the parity bit (P) is calculated from bits T22 to T00. This replaces the final bit, T23, and the whole is copied to the shift register. Data are transmitted in the order T00, T01, …, T22, and P.
In reception, received data are shifted in bit by bit through bit 8 of the shift register. When bits R00 to P have been collected after input of the required number of cycles of RSPCK, the value in the shift register is copied to the reception buffer. On copying of data to the shift register, the data from R00 to P are checked by judging the parity. At this time, the higher-order 8 bits of the transmission buffer are stored in the higher-order 8 bits of the reception buffer. Writing 0 to bits T31 to T24 at the time of transmission leads to 0 being inserted in the higher-order 8 bits of the reception buffer.



Note: Output = MOSI (master)/MISO (slave), input = MISO (master)/MOSI (slave)

Figure 36.21 LSB First Transfer (24-Bit Data, Parity Enabled)

36.3.5 Transfer Format

36.3.5.1 CPHA = 0

Figure 36.22 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 0. Note that clock synchronous operation (the SPCR.SPMS bit is 1) should not be set when the RSPI operates in slave mode (SPCR.MSTR = 0) and the CPHA bit is 0. In Figure 36.22, RSPCKy (CPOL = 0) indicates the RSPCKy signal waveform when the SPCMDm.CPOL bit is 0; RSPCKy (CPOL = 1) indicates the RSPCKy signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI settings. For details, refer to section 36.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 0, the driving of valid data to the MOSIy and MISOy signals commences at an SSLyi signal assertion timing. The first RSPCKy signal change timing that occurs after the SSLyi signal assertion becomes the first transfer data fetch timing. After this timing, data is sampled at every 1 RSPCK cycle. The change timing for MOSIy and MISOy signals is always 1/2 RSPCK cycles after the transfer data fetch timing. The CPOL bit setting does not affect the RSPCK signal operation timing; it only affects the signal polarity.

t1 denotes a period from an SSLyi signal assertion to RSPCKy oscillation (RSPCK delay). t2 denotes a period from the termination of RSPCKy oscillation to an SSLyi signal negation (SSL negation delay). t3 denotes a period in which SSLyi signal assertion is suppressed for the next transfer after the end of serial transfer (next-access delay). t1, t2, and t3 are controlled by a master device running on the RSPI system. For a description of t1, t2, and t3 when the RSPI of this LSI is in master mode, refer to section 36.3.10.1, Master Mode Operation.

(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

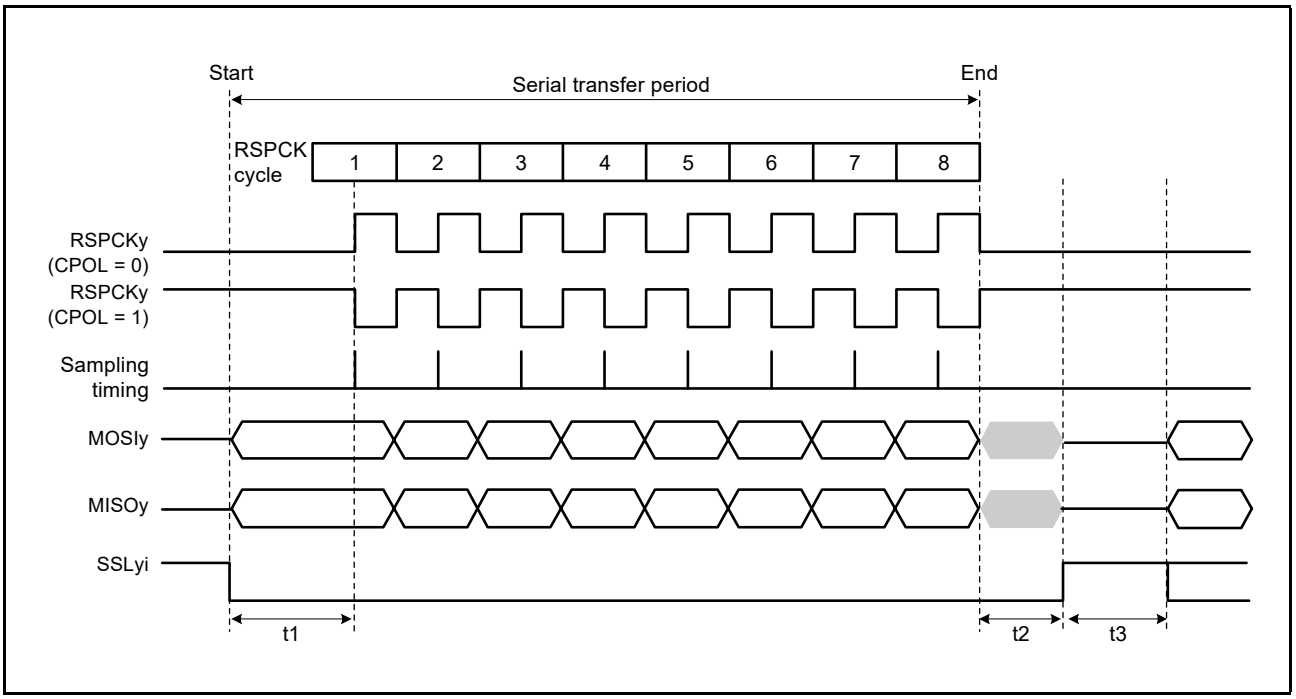


Figure 36.22 RSPI Transfer Format (CPHA = 0)

36.3.5.2 CPHA = 1

Figure 36.23 shows a sample transfer format for the serial transfer of 8-bit data when the SPCMDm.CPHA bit is 1. However, when the SPCR.SPMS bit is 1, the SSLyi signals are not used, and only the three signals RSPCKy, MOSIy, and MISOy handle communications. In Figure 36.23, RSPCK (CPOL = 0) indicates the RSPCKy signal waveform when the SPCMDm.CPOL bit is 0; RSPCK (CPOL = 1) indicates the RSPCKy signal waveform when the CPOL bit is 1. The sampling timing represents the timing at which the RSPI fetches serial transfer data into the shift register. The I/O directions of the signals depend on the RSPI mode (master or slave). For details, refer to section 36.3.2, Controlling RSPI Pins.

When the SPCMDm.CPHA bit is 1, the driving of invalid data to the MISOy signal commences at an SSLyi signal assertion timing. The output of valid data to the MOSIy and MISOy signals commences at the first RSPCKy signal change timing that occurs after the SSLyi signal assertion. After this timing, data is updated at every 1 RSPCK cycle. The transfer data fetch timing is always 1/2 RSPCK cycles after the data update timing. The SPCMDm.CPOL bit setting does not affect the RSPCKy signal operation timing; it only affects the signal polarity.

t1, t2, and t3 are the same as those in the case of CPHA = 0. For a description of t1, t2, and t3 when the RSPI of this LSI is in master mode, refer to section 36.3.10.1, Master Mode Operation.

(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

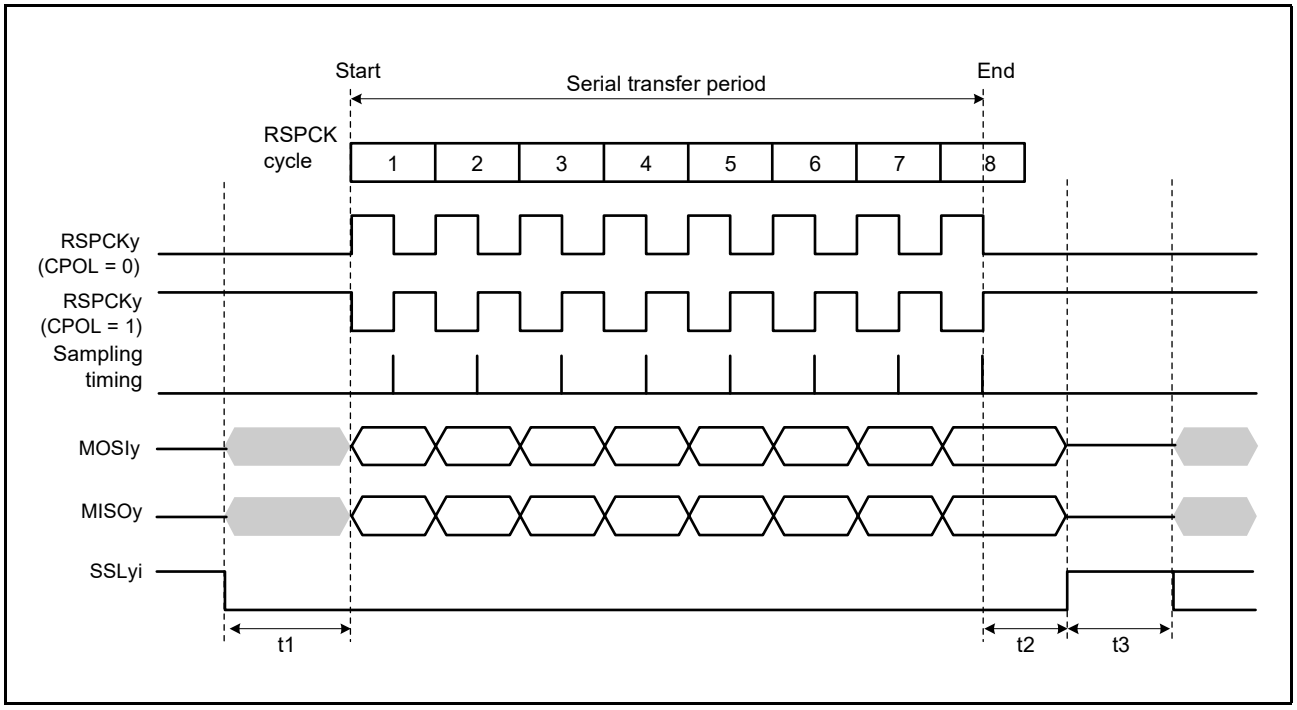

Figure 36.23 RSPI Transfer Format (CPHA = 1)

36.3.6 Communications Operating Mode

Full-duplex synchronous serial communications or transmit operations only can be selected by the communications operating mode select bit (SPCR.TXMD). The SPDR access shown in Figure 36.24 and Figure 36.25 indicates the condition of access to the SPDR register, where W denotes a write cycle.

36.3.6.1 Full-Duplex Synchronous Serial Communications (SPCR.TXMD = 0)

Figure 36.24 shows an example of operation when the communications operating mode select bit (SPCR.TXMD) is set to 0. In the example in Figure 36.24, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKy waveform represent the number of RSPCK cycles (i.e., the number of transferred bits) (m = 0 to 7; y = 0, 1, 2, 3 (for all channels)).

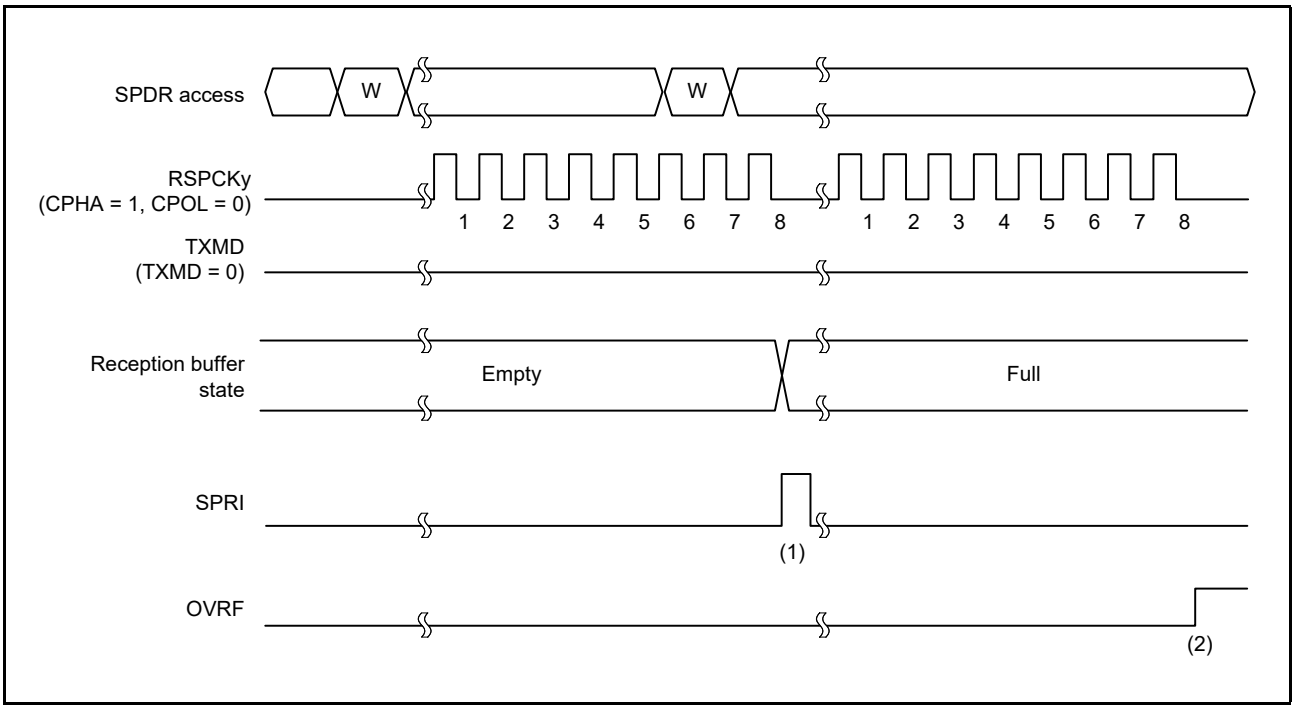

Figure 36.24 Operation Example of SPCR.TXMD = 0

The operation of the flags at timings shown in steps (1) and (2) in the figure is described below.

(1) When a serial transfer ends with the reception buffer of SPDR empty, the RSPI generates a reception buffer full interrupt request (SPRI) and copies the received data in the shift register to the reception buffer.

(2) When a serial transfer ends with the reception buffer of SPDR holding data that was received in the previous serial transfer, the RSPI sets the SPSR.OVRF flag to 1 and discards the received data in the shift register.

36.3.6.2 Transmit Operations Only (SPCR.TXMD = 1)

Figure 36.25 shows an example of operation when the communications operating mode select bit (SPCR.TXMD) is set to 1. In the example in Figure 36.25, the RSPI performs an 8-bit serial transfer in which the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKy waveform represent the number of RSPCK cycles (i.e., the number of transferred bits) (m = 0 to 7; y = 0, 1, 2, 3 (for all channels)).

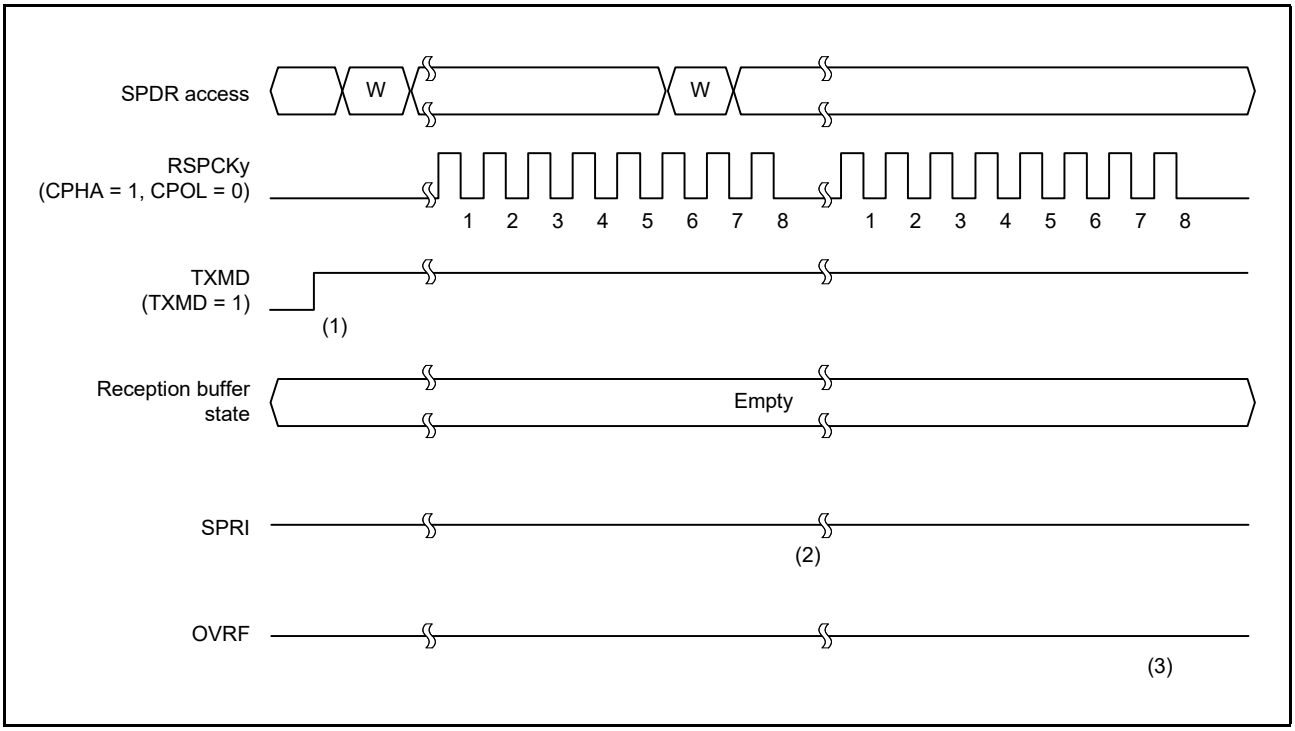

Figure 36.25 Operation Example of SPCR.TXMD = 1

The operation of the flags at timings shown in steps (1) to (3) in the figure is described below.

(1) Make sure there is no data left in the reception buffer and the SPSR.OVRF flag is 0 before entering the mode of transmit operations only (SPCR.TXMD = 1).

(2) When a serial transfer ends with the reception buffer of SPDR empty, if the mode of transmit operations only is selected (SPCR.TXMD = 1), the RSPI does not copy the data in the shift register to the reception buffer.

(3) Since the reception buffer of SPDR does not hold data that was received in the previous serial transfer, even when a serial transfer ends, the SPSR.OVRF flag retains the value of 0, and the data in the shift register is not copied to the reception buffer.

When performing transmit operations only (SPCR.TXMD = 1), the RSPI transmits transmit data but does not receive received data. Therefore, the SPSR.OVRF flag remains 0 at the timings of (1) to (3).

36.3.7 Transmission Buffer Empty/Reception Buffer Full Interrupts

Figure 36.26 shows an example of operation of the transmission buffer empty interrupt (SPTI) and the reception buffer full interrupt (SPRI). The SPDR register access shown in Figure 36.26 indicates the condition of access to the SPDR register, where W denotes a write cycle, and R a read cycle. In the example in Figure 36.26, the RSPI performs an 8-bit serial transfer in which the SPCR.TXMD bit is 0, the SPDCR.SPFC[1:0] bits are 00b, the SPCMDm.CPHA bit is 1, and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKy waveform represent the number of RSPCK cycles (i.e., the number of transferred bits) (m = 0 to 7; y = 0, 1, 2, 3 (for all channels)).

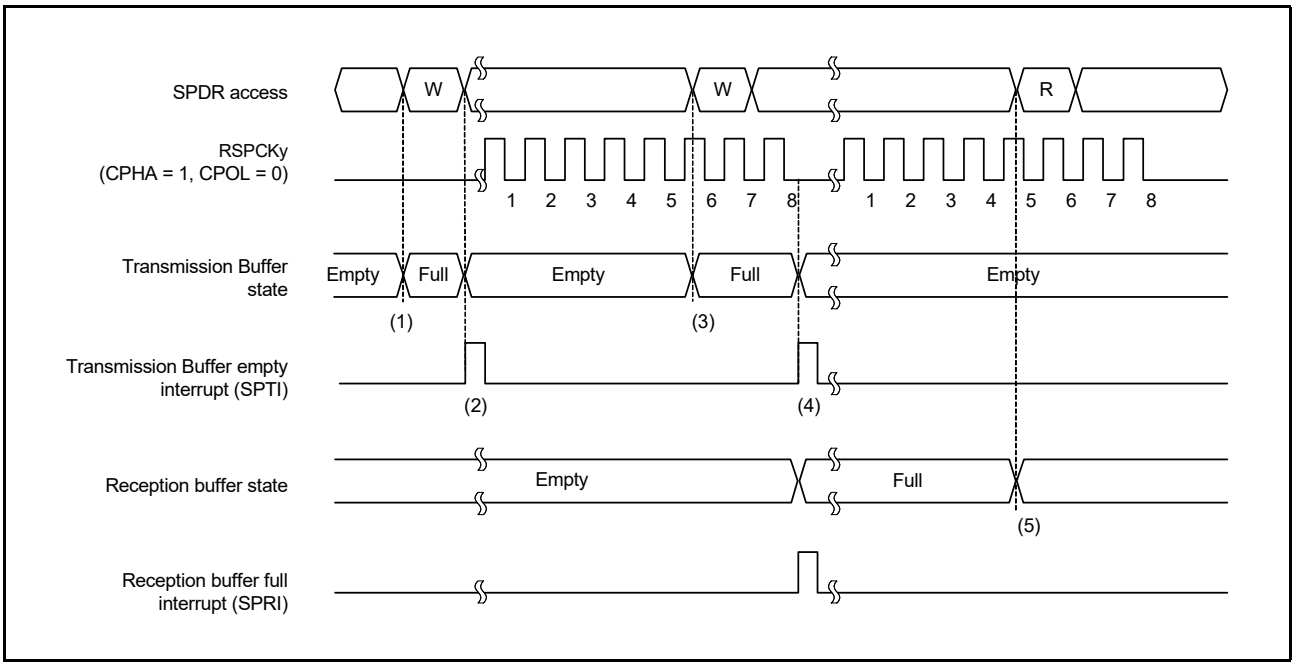

Figure 36.26 Operation Example of Transmission Buffer Empty Interrupt (SPTI) and Reception Buffer Full Interrupt (SPRI)

The operation of the interrupts at timings shown in steps (1) to (5) in the figure is described below.

1. When transmit data is written to SPDR when the transmission buffer of SPDR is empty (data for the next transfer is not set), the RSPI writes data to the transmission buffer.
2. If the shift register is empty, the RSPI copies the data in the transmission buffer to the shift register and generates a transmission buffer empty interrupt request (SPTI). How a serial transfer is started depends on the mode of the RSPI. For details, refer to section 36.3.10, SPI Operation, and section 36.3.11, Clock Synchronous Operation.
3. When transmit data is written to SPDR by the transmission buffer empty interrupt routine, the data is transferred to the transmission buffer. Because the data being transferred serially is stored in the shift register, the RSPI does not copy the data in the transmission buffer to the shift register.
4. When the serial transfer ends with the reception buffer of SPDR being empty, the RSPI copies the receive data in the shift register to the reception buffer and generates a reception buffer full interrupt request (SPRI). Since the shift register becomes empty upon completion of serial transfer, when the transmission buffer had been full before the serial transfer ended, the RSPI copies the data in the transmission buffer to the shift register. Even when received data is not copied from the shift register to the reception buffer in an overrun error status, upon completion of the serial transfer, the RSPI determines that the shift register is empty, thus data transfer from the transmission buffer to the shift register is enabled.
5. When SPDR is read by the reception buffer full interrupt routine, the receive data can be read.

If SPDR is written to when the transmission buffer holds data that has not yet been transmitted, the RSPI does not update the data in the transmission buffer. When writing to SPDR, make sure to use a transmission buffer empty interrupt request. To use a transmission buffer empty interrupt, set the SPTIE bit in SPCR to 1.
If the RSPI function is disabled (the SPCR.SPE bit being 0), set the SPTIE bit to 0.
When serial transfer ends with the reception buffer being full, the RSPI does not copy data from the shift register to the reception buffer, and detects an overrun error (refer to section 36.3.8, Error Detection). To prevent a receive data overrun error, read the received data using a reception buffer full interrupt request before the next serial transfer ends. To use an RSPI reception buffer full interrupt, set the SPCR.SPRIE bit to 1.
For the states of the transmit and reception buffers, transmission buffer empty and reception buffer interrupts or the corresponding IRQ status register (IRQSn) can be used to confirm the generation of interrupt requests. For the IRQ status register (IRQSn), see section 12.4.2.1, IRQ Status Register n (IRQSn) (n = 0 to 9).

36.3.8 Error Detection

In the normal RSPI serial transfer, the data written to the transmission buffer of SPDR is transmitted, and the received data can be read from the reception buffer of SPDR. If access is made to SPDR, depending on the status of the transmission/reception buffer or the status of the RSPI at the beginning or end of serial transfer, in some cases non-normal transfers can be executed.
If a non-normal transfer operation occurs, the RSPI detects the event as an overrun error, parity error, or mode fault error. Table 36.8 lists the relationship between non-normal transfer operations and the RSPI's error detection function.

Table 36.8 Relationship between Non-Normal Transfer Operations and RSPI Error Detection Function

	Occurrence Condition	RSPI Operation	Error Detection
1	SPDR is written when the transmission buffer is full.	• The contents of the transmission buffer are kept. • Missing write data.	None
2	Serial transfer is started in slave mode when transmit data is still not loaded on the shift register.	Data received in previous serial transfer is transmitted.	None
3	SPDR is read when the reception buffer is empty.	Previously received data is output.	None
4	Serial transfer terminates when the reception buffer is full.	• The contents of the reception buffer are kept. • Missing receive data.	Overrun error
5	An incorrect parity bit is received when performing full-duplex synchronous serial communications with the parity function enabled.	The parity error flag is asserted.	Parity error
6	The SSLy0 input signal is asserted when the serial transfer is idle in multi-master mode.	• Driving of the RSPCKy, MOSIy, SSLy1 to SSLy3 output signals is stopped. • RSPI function is disabled.	Mode fault error
7	The SSLy0 input signal is asserted during serial transfer in multi-master mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the RSPCKy, MOSIy, SSLy1 to SSLy3 output signals is stopped. • RSPI function is disabled.	Mode fault error
8	The SSLy0 input signal is negated during serial transfer in slave mode.	• Serial transfer is suspended. • Missing transmit/receive data. • Driving of the MISOy output signal is stopped. • RSPI function is disabled.	Mode fault error

y = 0, 1, 2, 3 (for all channels)

On operation 1 described in Table 36.8, the RSPI does not detect an error. To prevent data omission during the writing to SPDR, write operations to SPDR should be executed using a transmission buffer empty interrupt request.
Likewise, the RSPI does not detect an error on operation 2. In a serial transfer that was started before the shift register was updated, the RSPI sends the data that was received in the previous serial transfer, and does not treat the operation indicated in 2 as an error. Note that the received data from the previous serial transfer is retained in the reception buffer of SPDR, thus it can be correctly read (if SPDR is not read before the end of the serial transfer, an overrun error may occur).
Similarly, the RSPI does not detect an error on operation 3. To prevent extraneous data from being read, SPDR read operation should be executed using an RSPI reception buffer full interrupt request.
An overrun error shown in 4 is described in section 36.3.8.1, Overrun Error. A parity error shown in 5 is described in section 36.3.8.2, Parity Error. A mode fault error shown in 6 to 8 is described in section 36.3.8.3, Mode Fault Error. For the transmit and receive interrupts, refer to section 36.3.7, Transmission Buffer Empty/Reception Buffer Full Interrupts.

36.3.8.1 Overrun Error

If a serial transfer ends when the reception buffer of SPDR is full, the RSPI detects an overrun error, and sets the OVRF flag in SPSR to 1. When the OVRF flag is 1, the RSPI does not copy data from the shift register to the reception buffer so that the data prior to the occurrence of the error is retained in the reception buffer. To set the OVRF flag to 0, write 0 to the OVRF flag after the CPU has read SPSR with the OVRF flag set to 1.

Figure 36.27 shows an example of operation of the OVRF flag. The SPSR and SPDR accesses shown in Figure 36.27 indicate the condition of accesses to SPSR and SPDR, respectively, where W denotes a write cycle, and R a read cycle. In the example in Figure 36.27, the RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKy waveform represent the number of RSPCK cycles (i.e., the number of transferred bits) (m = 0 to 7; y = 0, 1, 2, 3 (for all channels)).

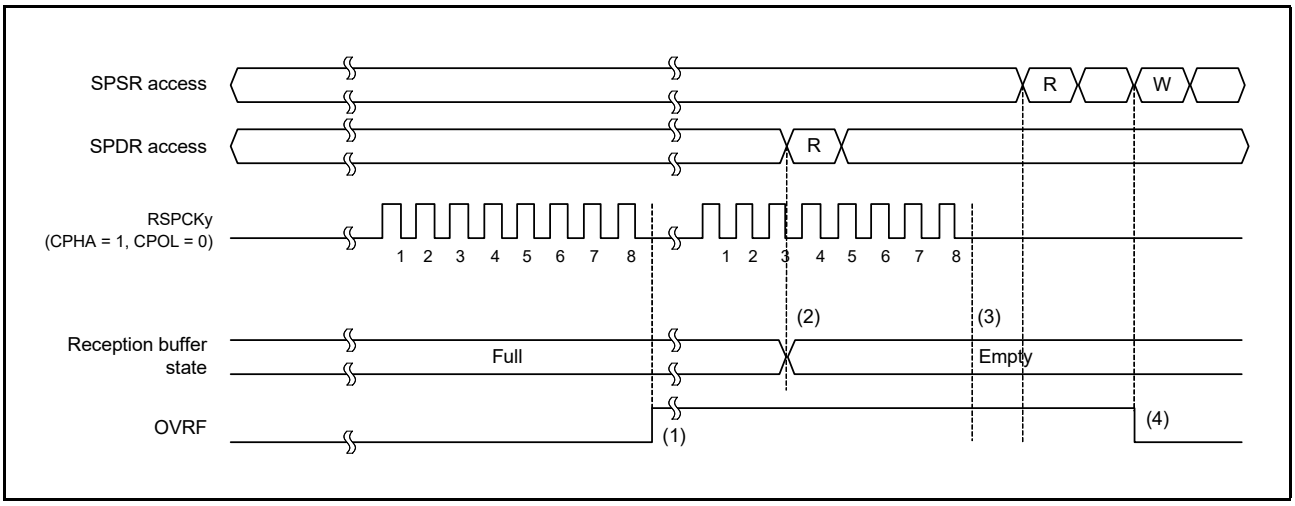

Figure 36.27 Operation Example of OVRF Flag

The operation of the flags at the timing shown in steps (1) to (4) in the figure is described below.

1. If a serial transfer terminates with the reception buffer full, the RSPI detects an overrun error, and sets the OVRF flag to 1. The RSPI does not copy the data in the shift register to the reception buffer. Even if the SPPE bit is 1, parity errors are not detected. In master mode, the RSPI copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.
2. When SPDR is read, the RSPI can read the data in the reception buffer. The reception buffer becoming empty does not set the OVRF flag to 0.
3. If the serial transfer ends with the OVRF flag being 1 (an overrun error occurs), the RSPI does not copy the data in the shift register to the reception buffer. A reception-buffer interrupt is not generated. Even if the SPPE bit is 1, parity errors are not detected. When in master mode, the RSPI does not update the SPSSR.SPECM[2:0] bits. When in an overrun error state and the RSPI does not copy the received data from the shift register to the reception buffer, upon termination of the serial transfer, the RSPI determines that the shift register is empty; in this manner, data transfer from the transmission buffer to the shift register is enabled.
4. If the value 0 is written to the OVRF flag after SPSR is read when the OVRF flag is 1, the OVRF flag is set to 0.

The occurrence of an overrun can be checked either by reading SPSR or by using an RSPI error interrupt and reading SPSR. When executing a serial transfer, measures should be taken to ensure the early detection of overrun errors, such as reading SPSR immediately after SPDR is read. When the RSPI is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

If an overrun error occurs and the OVRF flag is set to 1, normal reception operations cannot be performed until the OVRF flag is set to 0.

When the RSPCK auto-stop function is enabled in master mode, an overrun error does not occur. Figure 36.28 and Figure 36.29 show the clock stop waveform when a serial transfer continues while the reception buffer is full in master mode.

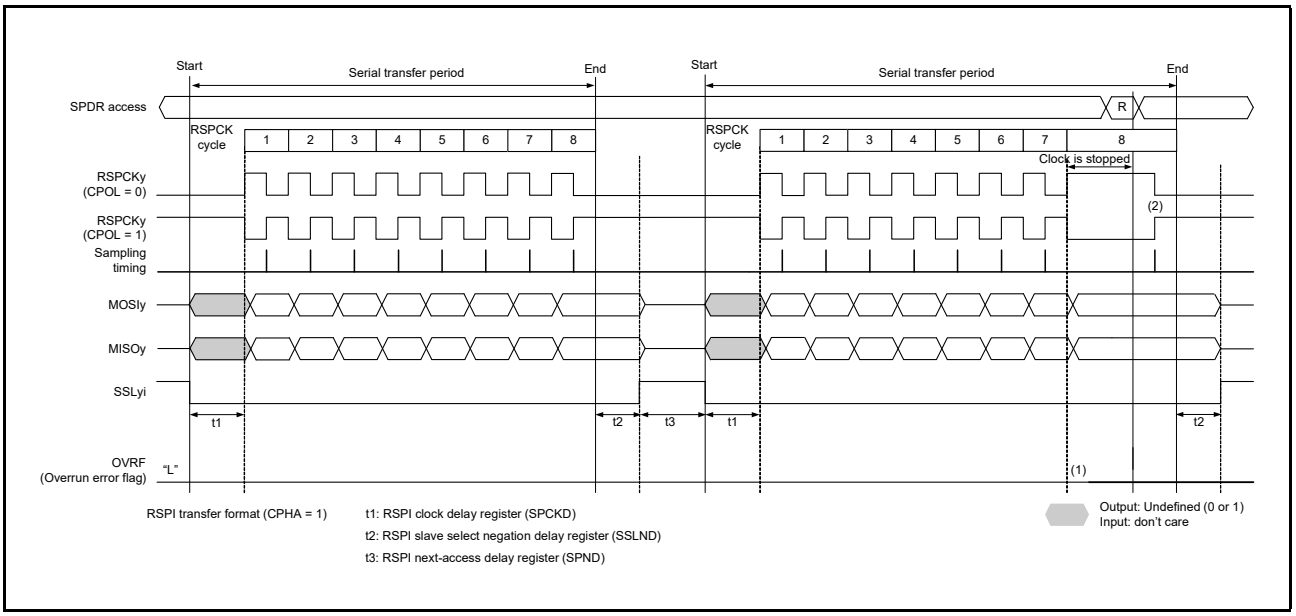

Figure 36.28 Clock Stop Waveform When a Serial Transfer Continues While the Reception Buffer is Full in Master Mode (CPHA = 1)

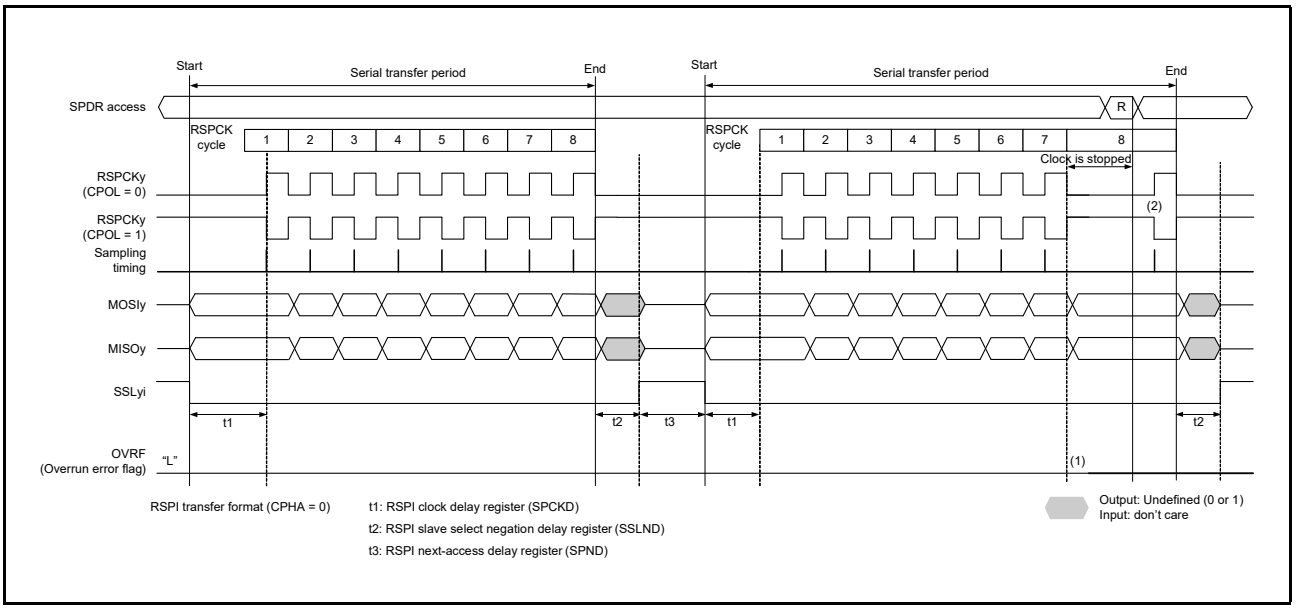

Figure 36.29 Clock Stop Waveform When a Serial Transfer Continues While the Reception Buffer is Full in Master Mode (CPHA = 0)

The operation of the flags at the timings shown in steps (1) and (2) in the figure is described below.

(1) When the reception buffer is full, an overrun error to stop the reception buffer does not occur.

(2) If SPDR is read while the clock is stopped, data in the reception buffer can be read. The RSPCK clock restarts after reading the reception buffer.

36.3.8.2 Parity Error

If full-duplex synchronous serial communications is performed with the SPCR.TXMD bit set to 0 and the SPCR2.SPPE bit set to 1, when serial transfer ends, the RSPI checks whether there are parity errors. Upon detecting a parity error in the received data, the RSPI sets the SPSR.PERF flag to 1. Since the RSPI does not copy the data in the shift register to the reception buffer when the SPSR.OVRF flag is set to 1, parity error detection is not performed for the received data. To set the PERF flag to 0, write 0 to the PERF flag after SPSR register is read with the PERF flag set to 1.
Figure 36.30 shows an example of operation of the OVRF and PERF flags. The SPSR access shown in Figure 36.30 indicates the condition of access to SPSR register, where W denotes a write cycle, and R a read cycle. In the example of Figure 36.30, full-duplex synchronous serial communications is performed while the SPCR.TXMD bit is 0 and the SPCR2.SPPE bit is 1. The RSPI performs an 8-bit serial transfer in which the SPCMDm.CPHA bit is 1 and the SPCMDm.CPOL bit is 0. The numbers given under the RSPCKy waveform represent the number of RSPCK cycles (i.e., the number of transferred bits) (m = 0 to 7; y = 0, 1, 2, 3 (for all channels)).

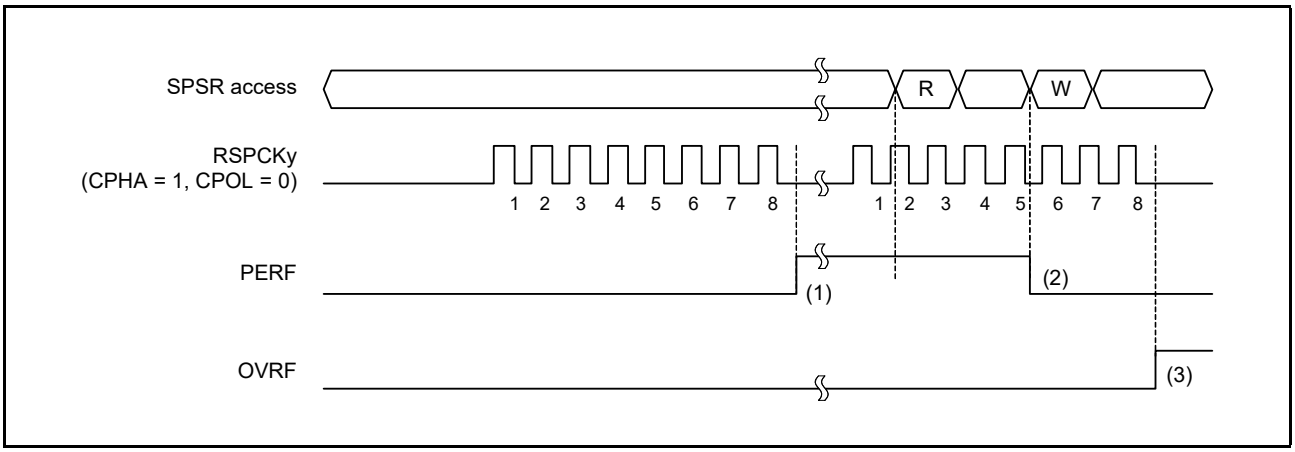

Figure 36.30 Operation Example of PERF Flag

The operation of the flags at the timing shown in steps (1) to (3) in the figure is described below.

1. If a serial transfer terminates with the RSPI not detecting an overrun error, the RSPI copies the data in the shift register to the reception buffer. The RSPI judges the received data at this timing, and sets the PERF flag to 1 if a parity error is detected. In master mode, the RSPI copies the pointer value to SPCMDm register to the SPSSR.SPECM[2:0] bits.
2. If the value 0 is written to the PERF flag after SPSR register is read when the PERF flag is 1, the PERF flag is set to 0.
3. When the RSPI detects an overrun error and serial transfer is terminated, the data in the shift register is not copied to the reception buffer. The RSPI does not perform parity error detection at this timing.

The occurrence of a parity error can be checked either by reading SPSR register or by using an RSPI error interrupt and reading SPSR register. When executing a serial transfer, measures should be taken to ensure the early detection of parity errors, such as reading SPSR. When the RSPI is used in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

36.3.8.3 Mode Fault Error

The RSPI operates in multi-master mode when the SPCR.MSTR bit is 1, the SPCR.SPMS bit is 0, and the SPCR.MODFEN bit is 1. If the active level is input with respect to the SSLy0 input signal of the RSPI in multi-master mode, the RSPI detects a mode fault error irrespective of the status of the serial transfer, and sets the MODF bit in the RSPI status register (SPSR) to 1. Upon detecting the mode fault error, the RSPI copies the value of the pointer to SPCMDm to the SPSSR.SPECM[2:0] bits. The active level of the SSLy0 signal is determined by the SSL0P bit in the RSPI slave select polarity register (SSLP).

When the MSTR bit is 0, the RSPI operates in slave mode. The RSPI detects a mode fault error if the MODFEN bit in the RSPI in slave mode is 1, and the SPMS bit is 0, and if the SSLy0 input signal is negated during the serial transfer period (from the time the driving of valid data is started to the time the final valid data is fetched).

Upon detecting a mode fault error, the RSPI stops driving of the output signals and clears the SPCR.SPE bit to 0 (refer to section 36.3.9, Initializing RSPI). In the case of multi-master configuration, detection of a mode fault error is used to stop driving of the output signals and the RSPI function, which allows the master right to be released.

The occurrence of a mode fault error can be checked either by reading SPSR or by using an RSPI error interrupt and reading SPSR. Detecting mode-fault errors without utilizing the RSPI error interrupt requires polling of SPSR. When using the RSPI in master mode, the pointer value to SPCMDm register at the occurrence of the error can be checked by reading the SPSSR.SPECM[2:0] bits.

When the MODF bit is 1, writing of the value 1 to the SPE bit is ignored by the RSPI. To enable the RSPI function after the detection of a mode fault error, the MODF bit must be set to 0 (m = 0 to 7; y = 0, 1, 2, 3 (for all channels)).

36.3.9 Initializing RSPI

If the value 0 is written to the SPCR.SPE bit or the RSPI sets the SPE bit to 0 because of the detection of a mode fault error, the RSPI disables the RSPI function, and initializes some of the module functions. When a system reset is generated, the RSPI initializes all of the module functions. The following describes initialization by the clearing of the SPCR.SPE bit and initialization by a system reset.

36.3.9.1 Initialization by Clearing the SPE Bit

When the SPCR.SPE bit is set to 0, the RSPI performs the following initialization:

- Suspending any serial transfer that is being executed
- Stopping the driving of output signals (Hi-Z) in slave mode
- Initializing the internal state of the RSPI
- Initializing the transmission buffer of the RSPI

Initialization by the clearing of the SPE bit does not initialize the control bits of the RSPI. For this reason, the RSPI can be started in the same transfer mode as prior to the initialization if the SPE bit is set to 1 again.
The SPSR.OVRF and SPSR.MODF flags are not initialized, nor is the value of the RSPI sequence status register (SPSSR) initialized. For this reason, even after the RSPI is initialized, data from the reception buffer can be read in order to check the status of error occurrence during an RSPI transfer.
The transmission buffer is initialized to an empty state. Therefore, if the SPCR.SPTIE bit is set to 1 after RSPI initialization, a transmission buffer empty interrupt is generated. When the RSPI is initialized, in order to disable any transmission buffer empty interrupt, the value 0 should be written to the SPTIE bit simultaneously with the writing of the value 0 to the SPE bit. To disable any transmission buffer empty interrupt after a mode fault error is detected, use an error handling routine to write the value 0 to the SPTIE bit.

36.3.9.2 System Reset

The initialization by a system reset completely initializes the RSPI through the initialization of all bits for controlling the RSPI, initialization of the status bits, and initialization of data registers, in addition to the requirements described in section 36.3.9.1, Initialization by Clearing the SPE Bit. For details, see section 6, Reset.

36.3.10 SPI Operation

36.3.10.1 Master Mode Operation

The only difference between single-master mode operation and multi-master mode operation lies in mode fault error detection (refer to section 36.3.8, Error Detection). When operating in single-master mode, the RSPI does not detect mode fault errors whereas the RSPI running in multi-master mode does detect mode fault errors. This section explains operations that are common to single-master mode and multi-master mode.

(1) Starting a Serial Transfer

The RSPI updates the data in the transmission buffer (SPTX) when data is written to the RSPI data register (SPDR) with the RSPI transmission buffer being empty (data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the RSPI copies data from the transmission buffer to the shift register and starts serial transfer. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format. The polarity of the SSLyi output pins depends on the SSLP register settings (i = 0 to 3; y = 0, 1, 2, 3 (for all channels)).

(2) Terminating a Serial Transfer

Irrespective of the SPCMDm.CPHA bit the RSPI terminates the serial transfer after transmitting an RSPCKy edge corresponding to the final sampling timing. If free space is available in the reception buffer (SPRX), upon termination of serial transfer, the RSPI copies data from the shift register to the reception buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting. The polarity of the SSLyi output pin depends on the SSLP register settings. For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format.
(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

(3) Sequence Control

The transfer format that is employed in master mode is determined by SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers.

SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in SPCMDm register: SSLyi pin output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCK polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, an RSPI clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.

According to the sequence length that is assigned to SPSCR, the RSPI makes up a sequence comprised of a part or all of SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in SPCMD0, and incorporates the SPCMD0 settings into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in SPCMD0, and in this manner the sequence is executed repeatedly.

(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

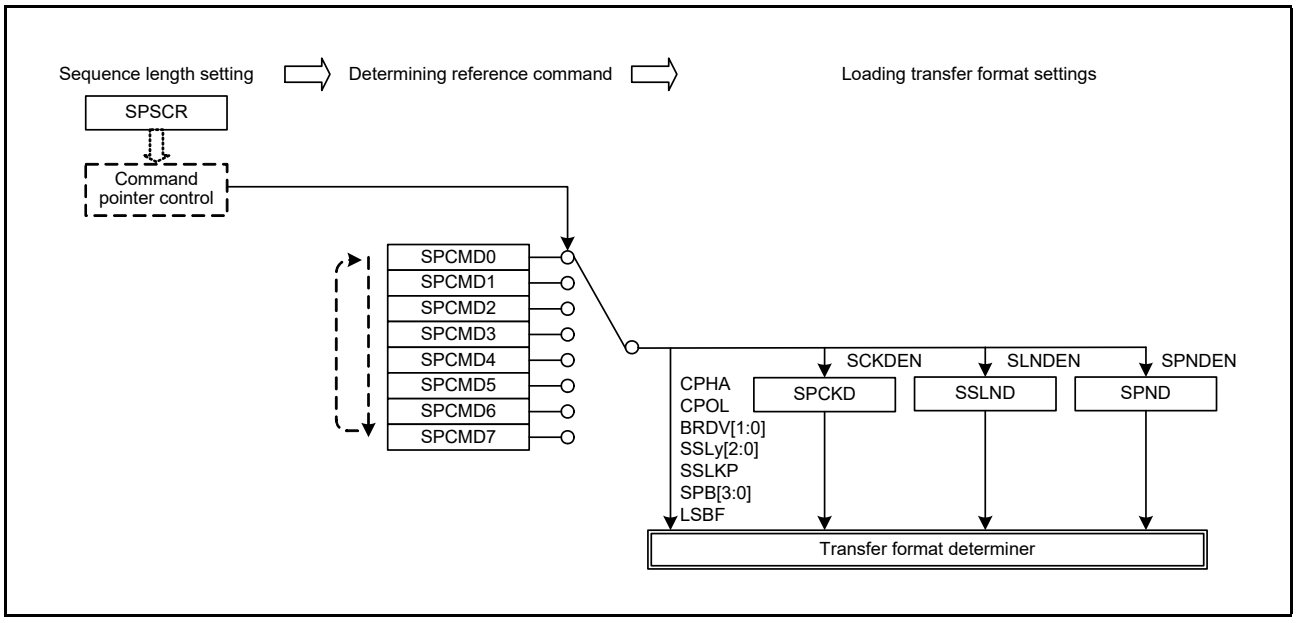

Figure 36.31 Procedure for Determining the Form of Serial Transfer in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm).

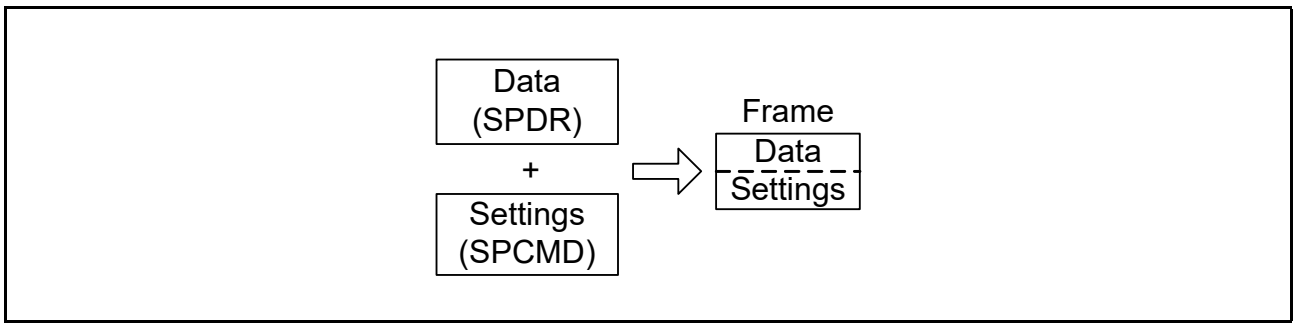

Figure 36.32 Concept of a Frame

Figure 36.33 shows the relationship between the command and the transmit and reception buffers in the sequence of operations specified by the settings in Table 36.4.

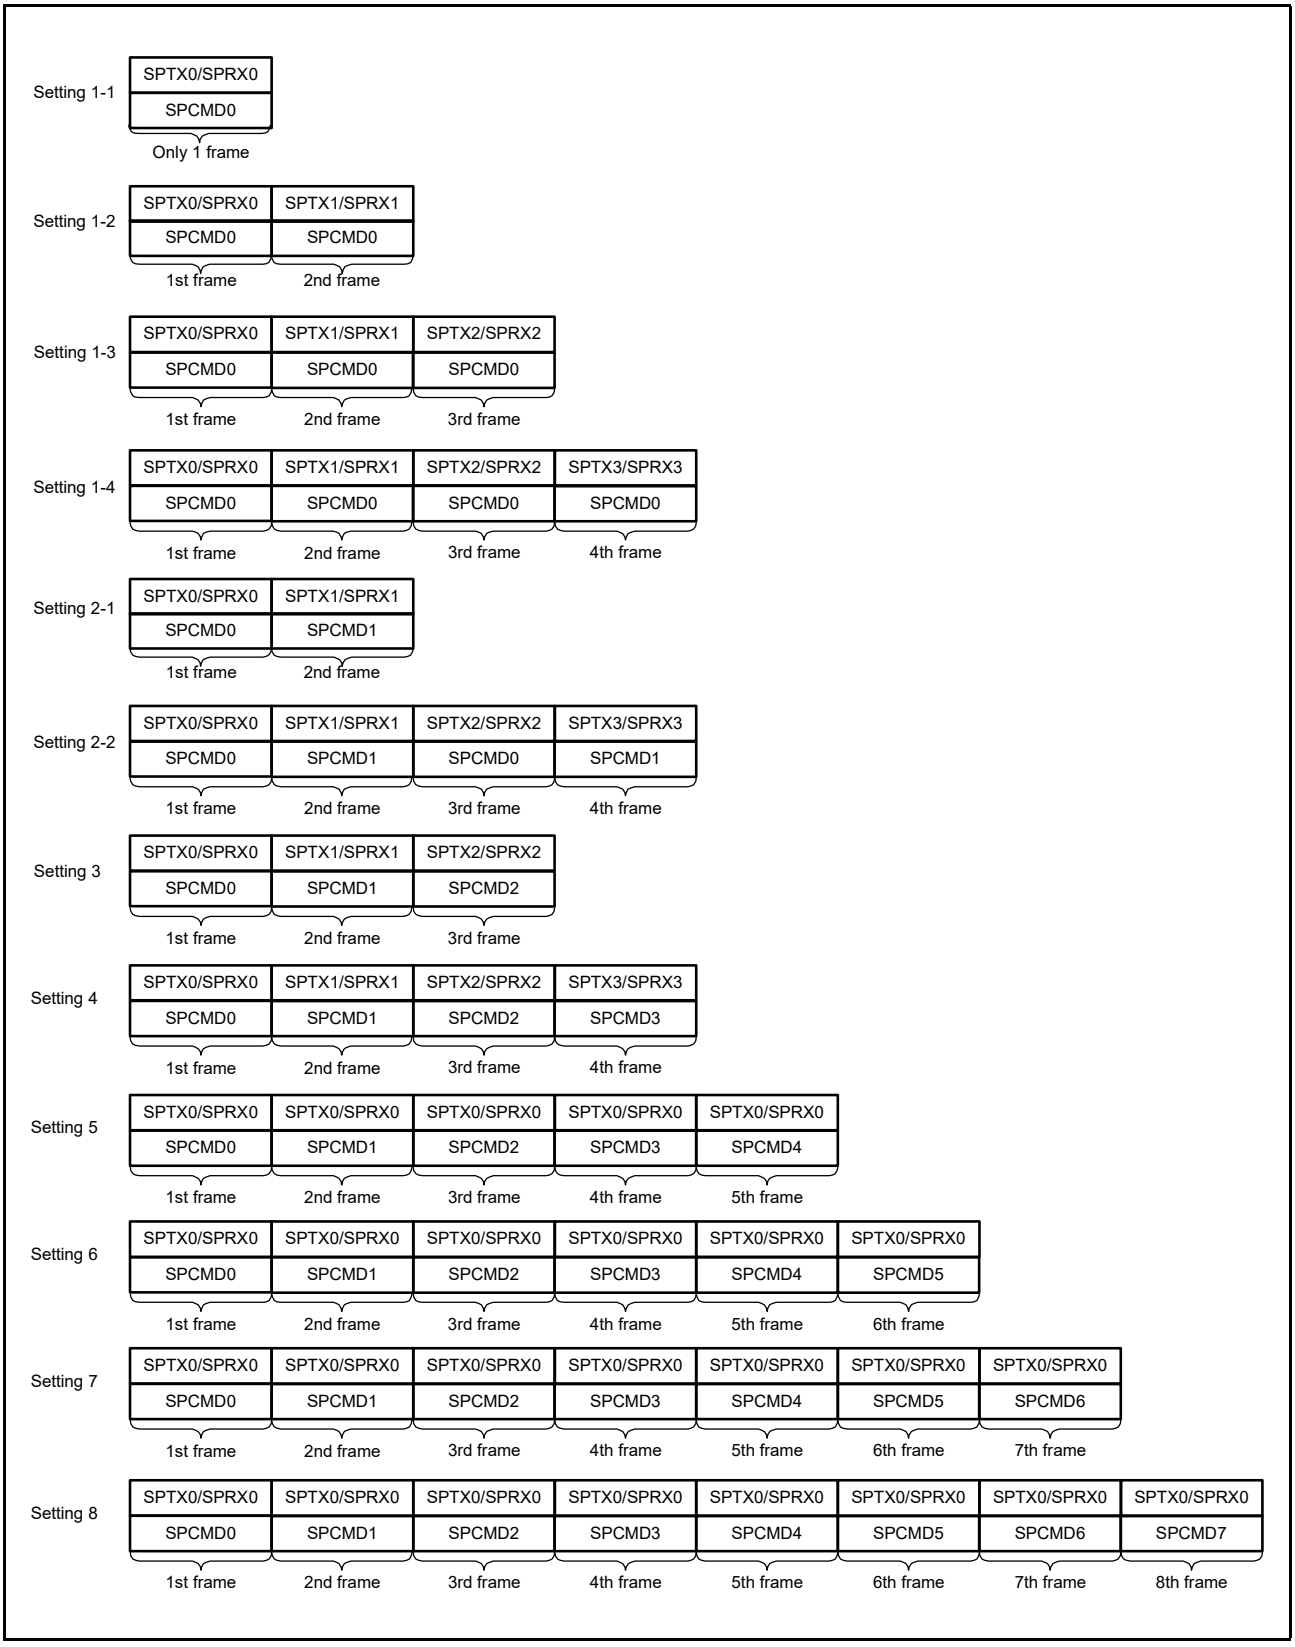

Figure 36.33 Correspondence between the RSPI Command Register and Transmission/Reception Buffers in Sequence Operations

(4) Burst Transfer

If the SPCMDm.SSLKP bit that the RSPI references during the current serial transfer is 1, the RSPI keeps the SSLyi signal level during the serial transfer until the beginning of the SSLyi signal assertion for the next serial transfer. If the SSLyi signal level for the next serial transfer is the same as the SSLyi signal level for the current serial transfer, the RSPI can execute continuous serial transfers while keeping the SSLyi signal assertion status (burst transfer).
Figure 36.34 shows an example of an SSLyi signal operation for the case where a burst transfer is implemented using SPCMD0 and SPCMD1 register settings. The text below explains the RSPI operations (1) to (7) as shown in Figure 36.34. It should be noted that the polarity of the SSLyi output signal depends on the SSLP register settings.

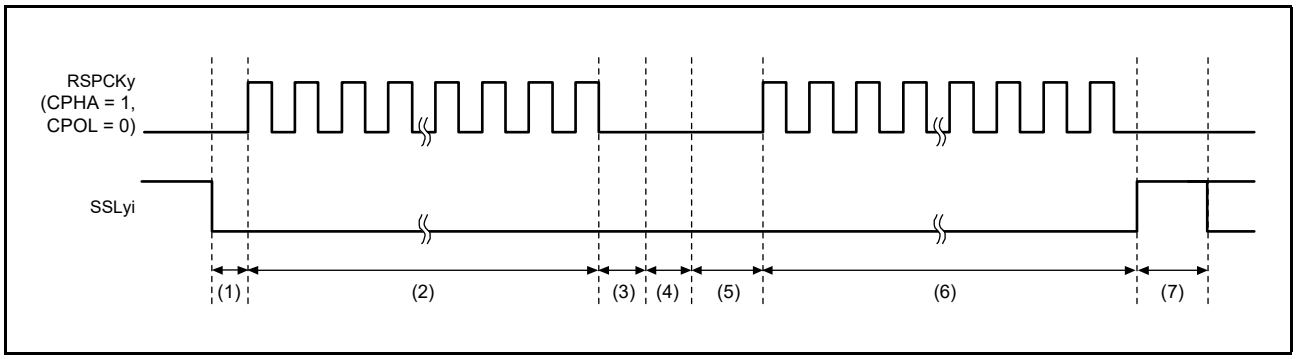

Figure 36.34 Example of Burst Transfer Operation Using SSLKP Bit

(1) Based on SPCMD0, the RSPI asserts the SSLyi signal and inserts RSPCK delays.
(2) The RSPI executes serial transfers according to SPCMD0.
(3) The RSPI inserts SSL negation delays.
(4) Since the SPCMD0.SSLKP bit is 1, the RSPI keeps the SSLyi signal value on SPCMD0. This period is sustained, at the shortest, for a period equal to the next-access delay of SPCMD0. If the shift register is empty after the passage of a minimum period, this period is sustained until the transmit data is stored in the shift register for the next transfer.
(5) Based on SPCMD1, the RSPI asserts the SSLyi signal and inserts RSPCK delays.
(6) The RSPI executes serial transfers according to SPCMD1.
(7) Because the SPCMD1.SSLKP bit is 0, the RSPI negates the SSLyi signal. In addition, a next-access delay is inserted according to SPCMD1.

If the SSLyi signal output settings in the SPCMDm register in which 1 is assigned to the SSLKP bit are different from the SSLyi signal output settings in the SPCMDm register to be used in the next transfer, the RSPI switches the SSLyi signal status to SSLyi signal assertion ((5) in Figure 36.34) corresponding to the command for the next transfer. Note that if such an SSLyi signal switching occurs, the slaves that drive the MISOy signal compete, and collision of signal levels may occur.
The RSPI in master mode references the SSLyi signal operation within the module for the case where the SSLKP bit is not used. Even when the SPCMDm.CPHA bit is 0, the RSPI can accurately start serial transfers by using the SSLyi signal assertion for the next transfer that is detected internally.
(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

(5) RSPCK Delay (t1)

The RSPCK delay value of the RSPI in master mode depends on the SPCMDm.SCKDEN bit setting and the SPCKD register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an RSPCK delay value during serial transfer by using the SPCMDm.SCKDEN bit and SPCKD, as listed in Table 36.9. For a definition of RSPCK delay, refer to section 36.3.5, Transfer Format.

Table 36.9 Relationship among SCKDEN Bit, SPCKD, and RSPCK Delay Value

SPCMDm.SCKDEN Bit	SPCKD.SCKDL[2:0] Bits	RSPCK Delay Value
0	000 to 111	1 RSPCK
1	000	1 RSPCK
	001	2 RSPCK
	010	3 RSPCK
	011	4 RSPCK
	100	5 RSPCK
	101	6 RSPCK
	110	7 RSPCK
	111	8 RSPCK

(6) SSL Negation Delay (t2)

The SSL negation delay value of the RSPI in master mode depends on the SPCMDm.SLNDEN bit setting and the SSLND register setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines an SSL negation delay value during serial transfer by using the SPCMDm.SLNDEN bit and SSLND, as listed in Table 36.10. For a definition of SSL negation delay, refer to section 36.3.5, Transfer Format.

Table 36.10 Relationship among SLNDEN Bit, SSLND, and SSL Negation Delay Value

SPCMDm.SLNDEN Bit	SSLND.SLNDL[2:0] Bits	SSL Negation Delay Value
0	000 to 111	1 RSPCK
1	000	1 RSPCK
	001	2 RSPCK
	010	3 RSPCK
	011	4 RSPCK
	100	5 RSPCK
	101	6 RSPCK
	110	7 RSPCK
	111	8 RSPCK

(7) Next-Access Delay (t3)

The next-access delay value of the RSPI in master mode depends on the SPCMDm.SPNDEN bit setting and the SPND setting. The RSPI determines the SPCMDm register to be referenced during serial transfer by pointer control, and determines a next-access delay value during serial transfer by using the SPCMDm.SPNDEN bit and SPND, as listed in Table 36.11. For a definition of next-access delay, refer to section 36.3.5, Transfer Format.

Table 36.11 Relationship among SPNDEN Bit, SPND, and Next-Access Delay Value

SPCMDm.SPNDEN Bit	SPND.SPNDL[2:0] Bits	Next-Access Delay Value
0	000 to 111	1 RSPCK + 2 SERICLK
1	000	1 RSPCK + 2 SERICLK
	001	2 RSPCK + 2 SERICLK
	010	3 RSPCK + 2 SERICLK
	011	4 RSPCK + 2 SERICLK
	100	5 RSPCK + 2 SERICLK
	101	6 RSPCK + 2 SERICLK
	110	7 RSPCK + 2 SERICLK
	111	8 RSPCK + 2 SERICLK

(8) Initialization Flowchart

Figure 36.35 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

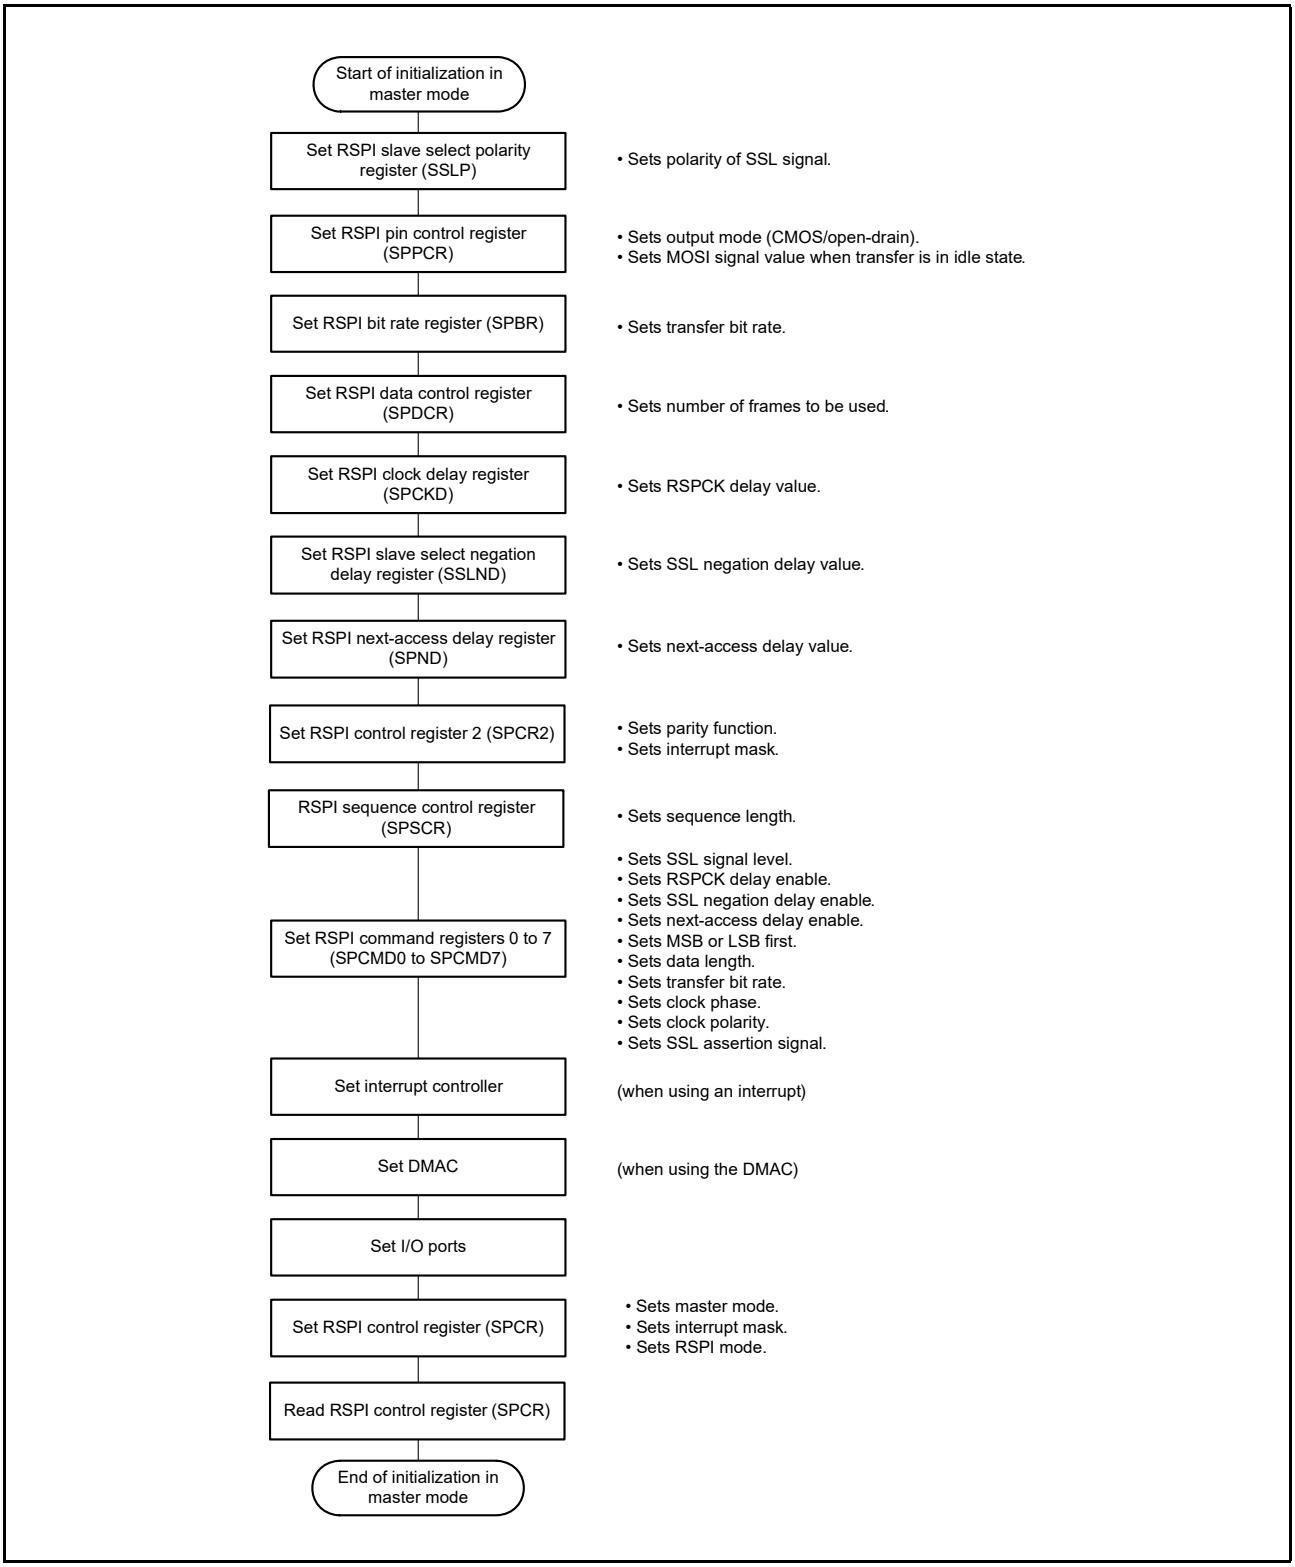

Figure 36.35 Example of Initialization Flowchart in Master Mode (SPI Operation)

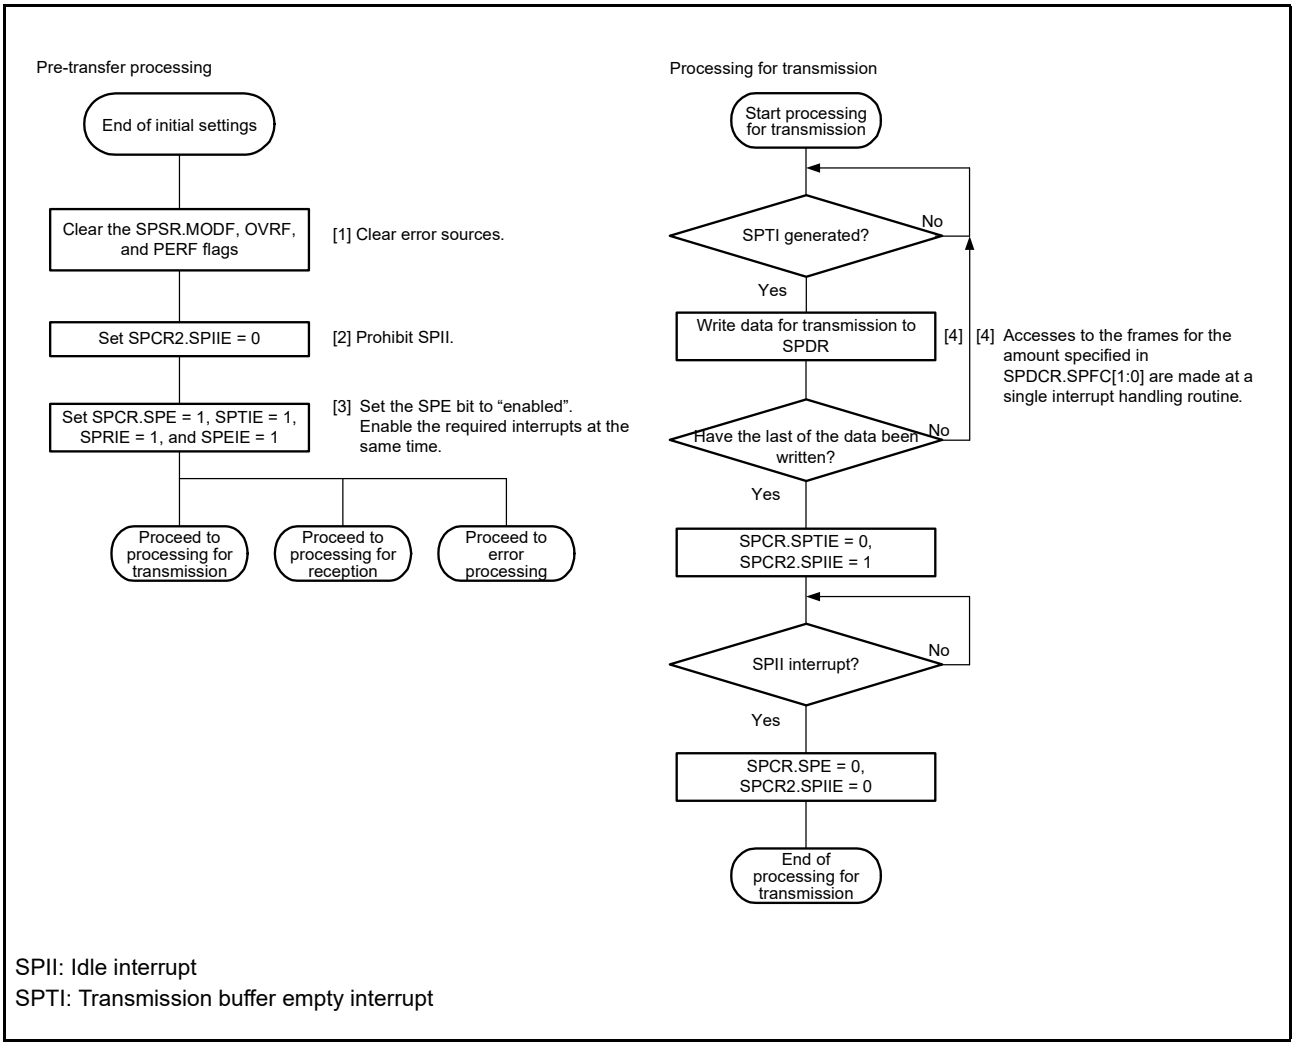
(9) Software Processing Flow

Figure 36.36 to Figure 36.38 show examples of the flow of software processing.

(a) Transmit Processing Flow

When transmitting data, the CPU will be notified of the completion of data transmission after the last writing of data for transmission if the idle interrupt (SPII) is enabled.



SPII: Idle interrupt
SPTI: Transmission buffer empty interrupt

Figure 36.36 Flowchart in Master Mode (Transmission)

(b) Receive Processing Flow

The RSPI does not handle receive-only operation, so processing for transmission is required if reception is to proceed.

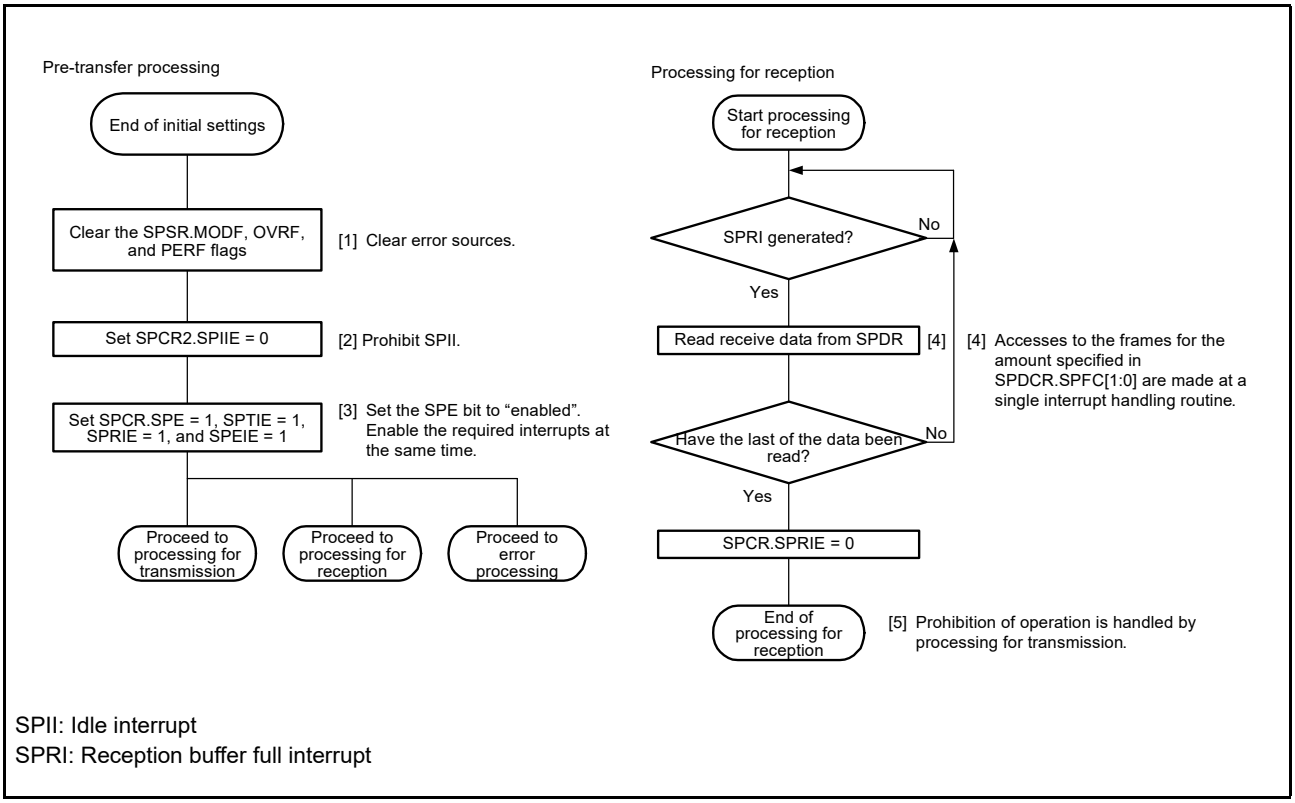


Figure 36.37 Flowchart in Master Mode (Reception)

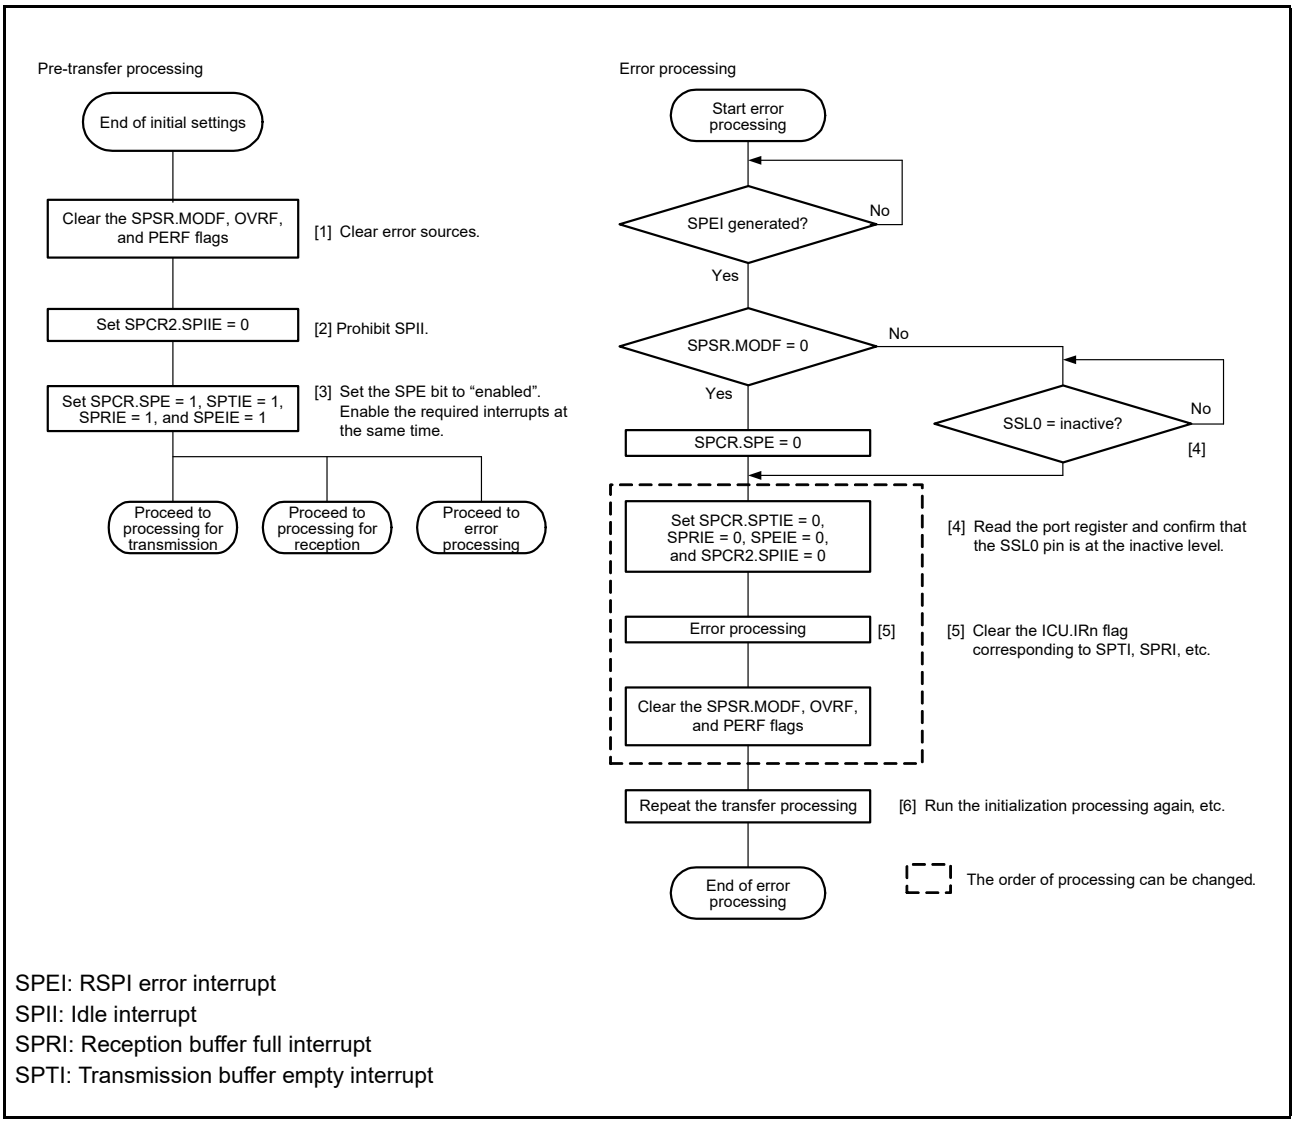
(c) Flow of error processing

The RSPI has three types of error. When a mode fault error is generated, the SPCR.SPE bit is automatically cleared, stopping operations for transmission and reception. For errors from other sources, however, the SPCR.SPE bit is not cleared and operations for transmission and reception continue; accordingly, we recommend clearing of the SPCR.SPE bit to stop operations in the case of errors other than mode-fault errors. Not doing so will lead to updating of the SPSSR.SPECM[2:0] bits.

When an error occurs, clear the corresponding flag of the IRQ status register from within the error processing routine. If this is not done, the corresponding interrupt request flag in the IRQ status register may continue to indicate a transmission buffer empty interrupt (SPTI) or reception buffer full interrupt (SPRI) request. If the reception buffer full interrupt (SPRI) request is indicated, read the reception buffer and initialize the sequencer in the RSPI.



SPEI: RSPI error interrupt
SPII: Idle interrupt
SPRI: Reception buffer full interrupt
SPTI: Transmission buffer empty interrupt

Figure 36.38 Flowchart for Master Mode (Error Processing)

36.3.10.2 Slave Mode Operation

(1) Starting a Serial Transfer

If the SPCMD0.CPHA bit is 0, when detecting an SSLy0 input signal assertion, the RSPI needs to start driving valid data to the MISOy output signal. For this reason, when the CPHA bit is 0, the assertion of the SSLy0 input signal triggers the start of a serial transfer.
If the CPHA bit is 1, when detecting the first RSPCKy edge in an SSLy0 signal asserted condition, the RSPI needs to start driving valid data to the MISOy output signal. For this reason, when the CPHA bit is 1, the first RSPCKy edge in an SSLy0 signal asserted condition triggers the start of a serial transfer.
When detecting the start of a serial transfer in a condition in which the shift register is empty, the RSPI changes the status of the shift register to “full”, so that data cannot be copied from the transmission buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, the RSPI leaves the status of the shift register unchanged, in the full state.
Irrespective of CPHA bit setting, the timing at which the RSPI starts driving of the MISOy output signal is the SSLy0 signal assertion timing. The data which is output by the RSPI is either valid or invalid, depending on the CPHA bit setting.
For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format. The polarity of the SSLy0 input signal depends on the setting of the SSLP.SSL0P bit.
(y = 0, 1, 2, 3 (for all channels))

(2) Terminating a Serial Transfer

Irrespective of the SPCMD0.CPHA bit, the RSPI terminates the serial transfer after detecting an RSPCKy edge corresponding to the final sampling timing. When free space is available in the reception buffer, upon termination of serial transfer the RSPI copies received data from the shift register to the reception buffer of the RSPI data register (SPDR). Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty”, regardless of the reception buffer state. A mode fault error occurs if the RSPI detects an SSLy0 input signal negation from the beginning of serial transfer to the end of serial transfer (refer to section 36.3.8, Error Detection).
The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting. The polarity of the SSLy0 input signal depends on the SSLP.SSL0P bit setting.
For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format.
(y = 0, 1, 2, 3 (for all channels))

(3) Notes on Single-Slave Operations

If the SPCMD0.CPHA bit is 0, the RSPI starts serial transfers when it detects the assertion edge for an SSLy0 input signal. In the type of configuration shown in Figure 36.7 as an example, if the RSPI is used in single-slave mode, the SSLy0 signal is always fixed at the active state. Therefore, when the CPHA bit is set to 0, the RSPI cannot correctly start a serial transfer. To correctly execute transmit/receive operations by the RSPI in slave mode in a configuration in which the SSLy0 input signal is fixed at the active state, the CPHA bit should be set to 1. If there is a need for setting the CPHA bit to 0, the SSLy0 input signal should not be fixed.
(y = 0, 1, 2, 3 (for all channels))

(4) Burst Transfer

If the SPCMD0.CPHA bit is 1, continuous serial transfer (burst transfer) can be executed while retaining the assertion state for the SSLy0 input signal. If the CPHA bit is 1, the period from the first RSPCKy edge to the sampling timing for the reception of the final bit in an SSLy0 signal active state corresponds to a serial transfer period. Even when the SSLy0 input signal remains at the active level, the RSPI can accommodate burst transfers because it can detect the start of an access.

If the CPHA bit is 0, the second and subsequent serial transfers during burst transfer cannot be executed correctly.

(5) Initialization Flowchart

Figure 36.39 is a flowchart illustrating an example of initialization in SPI operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

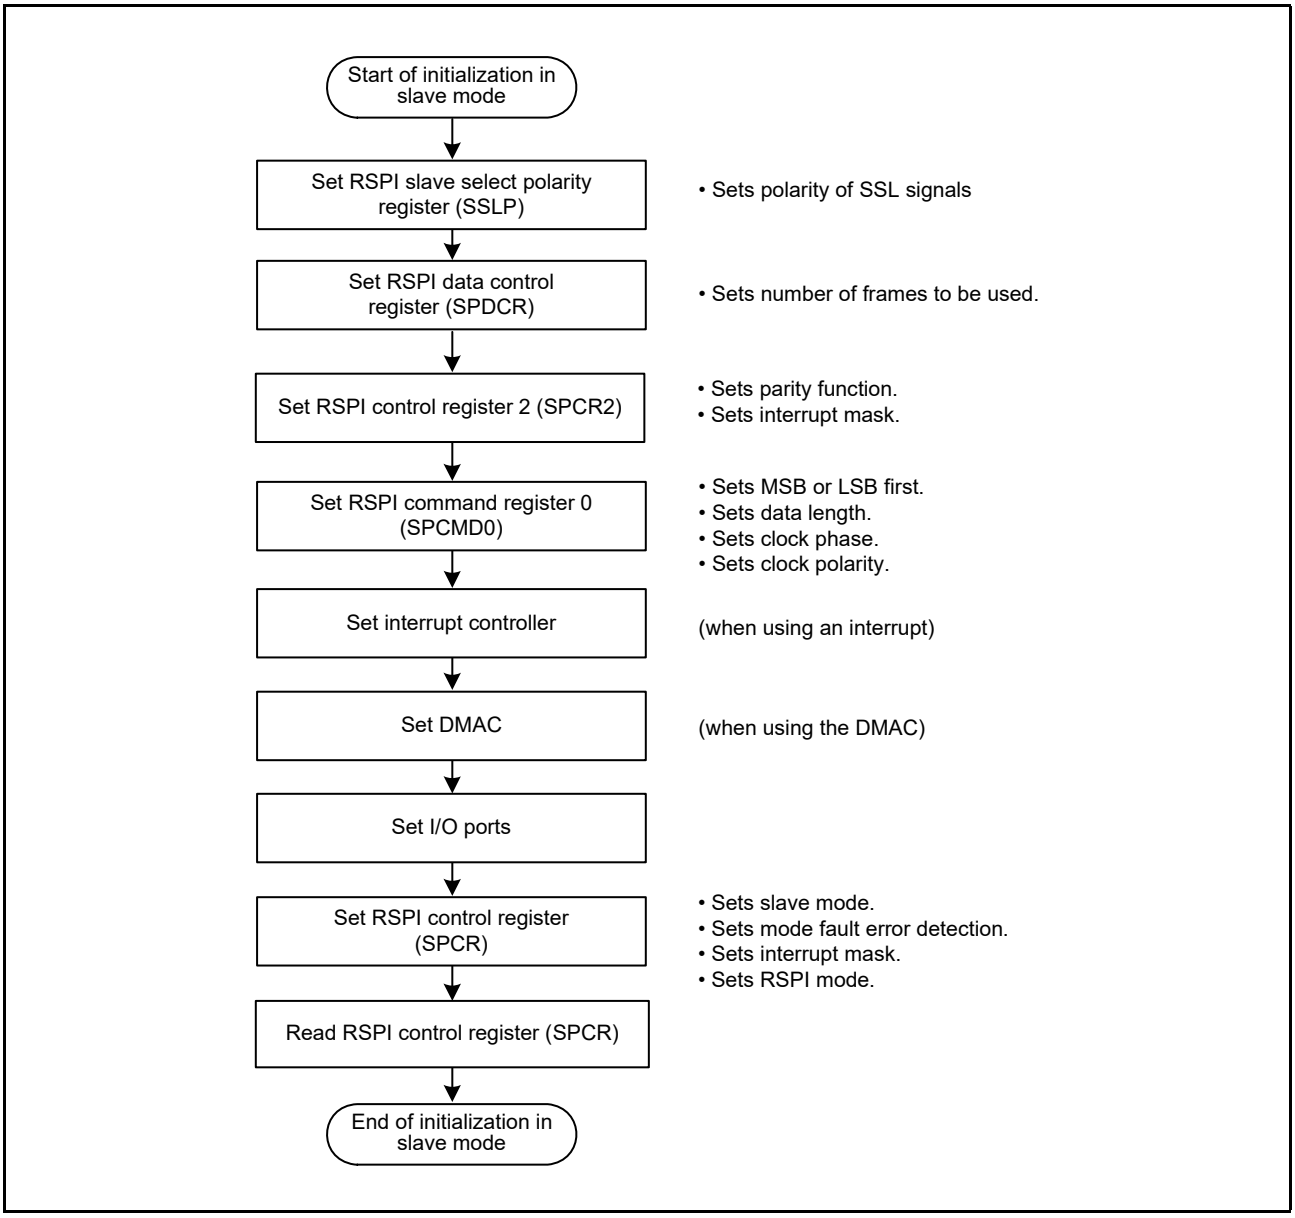


Figure 36.39 Example of Initialization Flowchart in Slave Mode (SPI Operation)

(6) Software Processing Flow

Figure 36.40 to Figure 36.42 show examples of the flow of software processing.

(a) Transmit Processing Flow

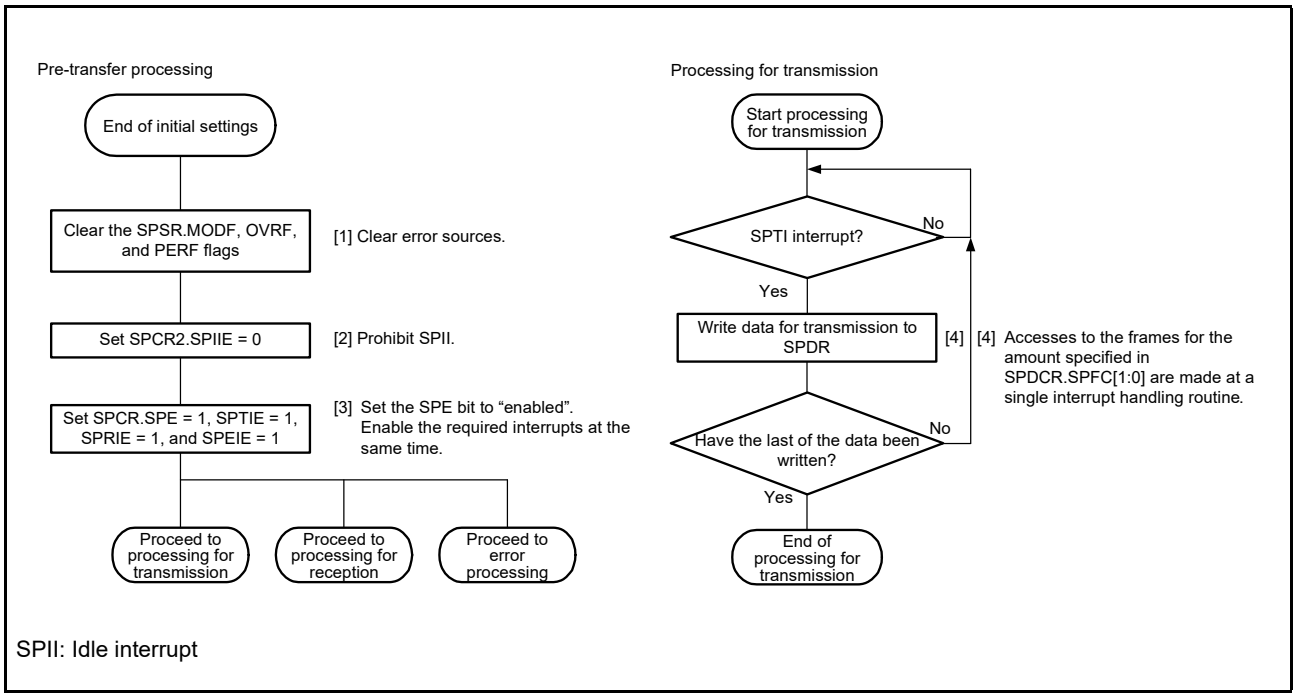

Figure 36.40 Flowchart in Slave Mode (Transmission)

(b) Receive Processing Flow

The RSPI does not handle receive-only operation, so processing for transmission is required if reception is to proceed.

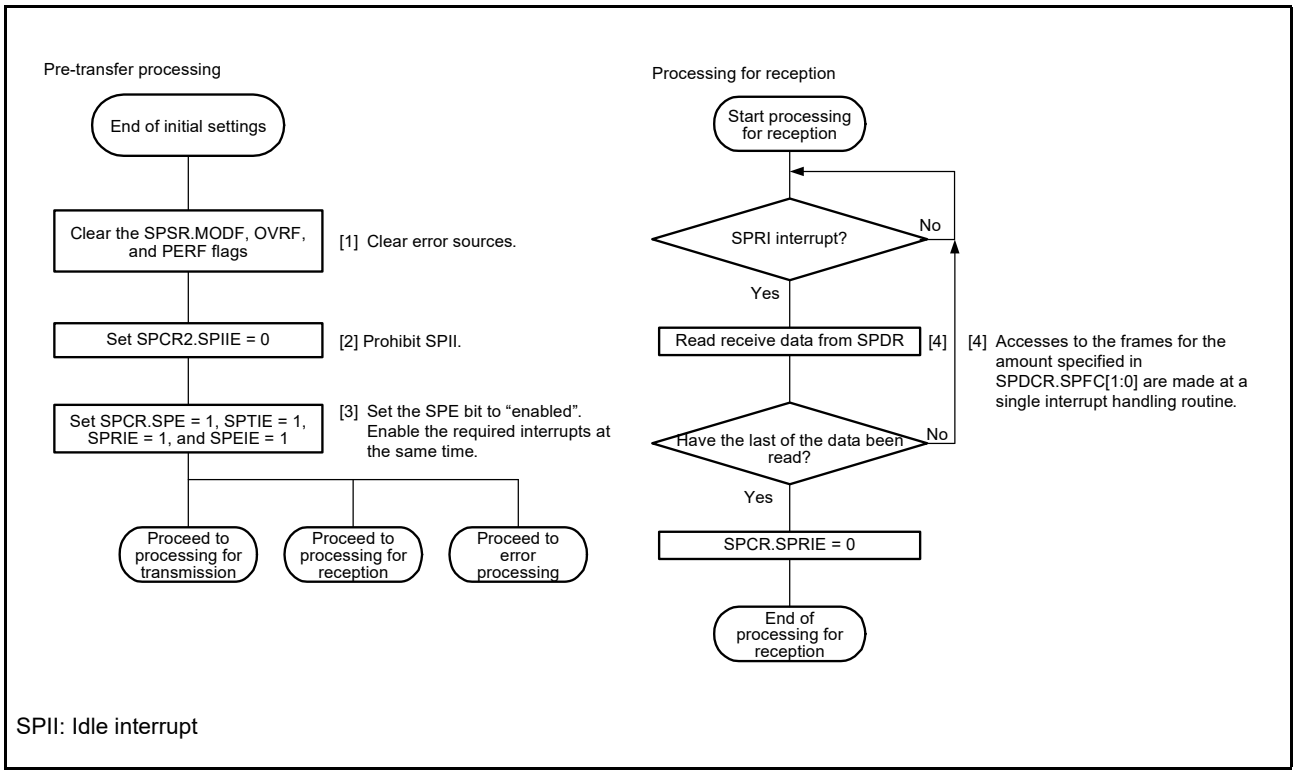

Figure 36.41 Flowchart in Slave Mode (Reception)

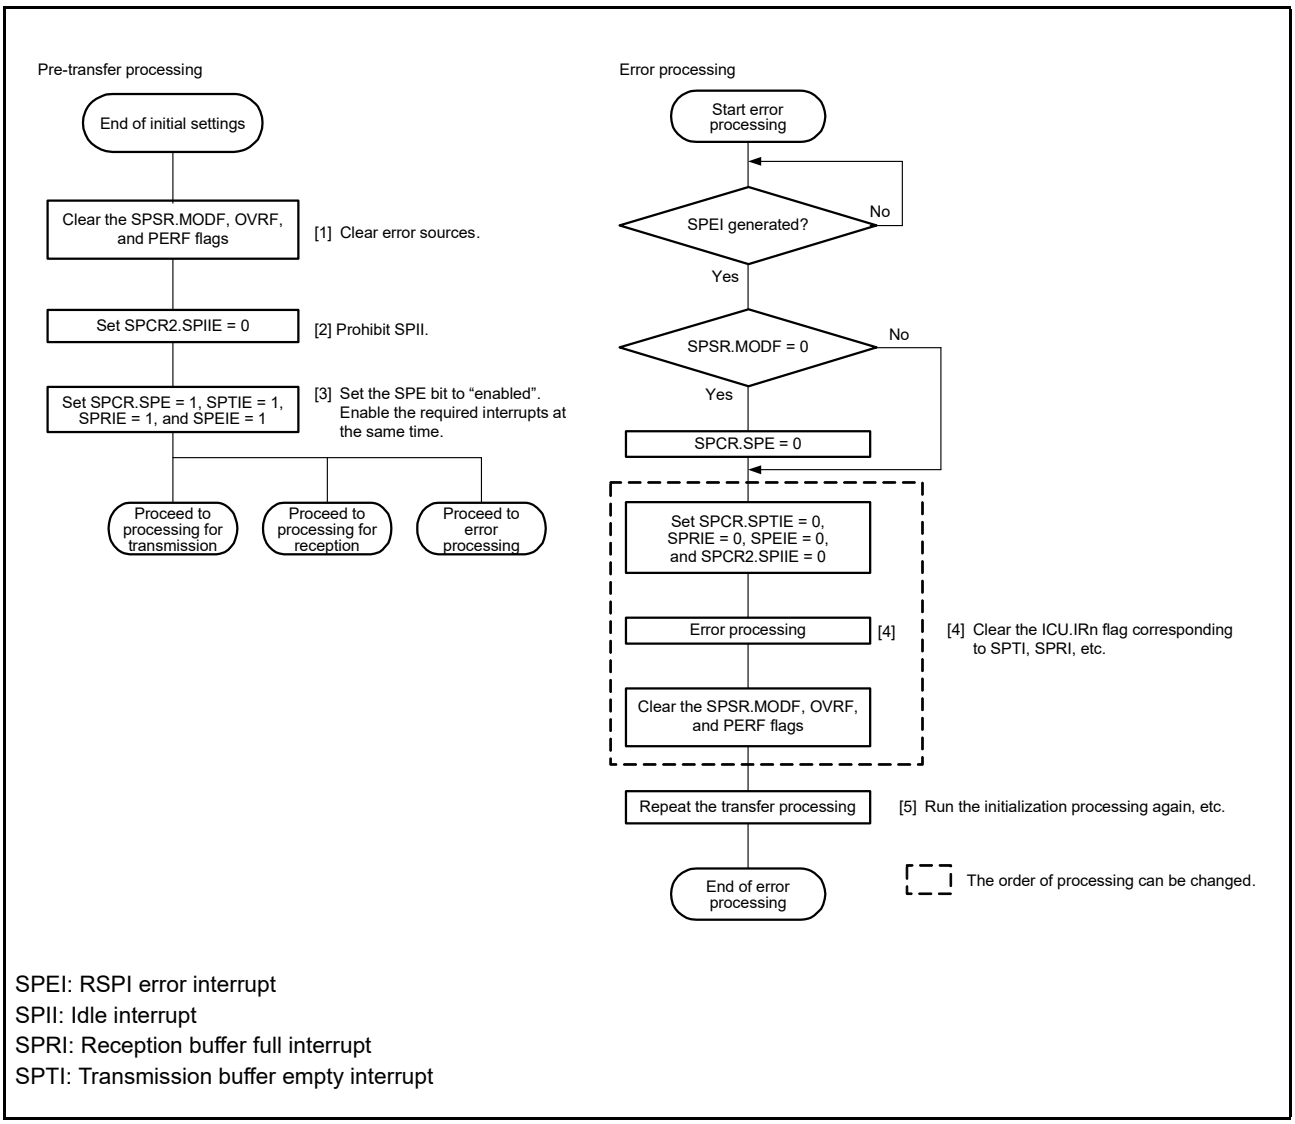
(c) Flow of error processing

In slave operation, even when a mode-fault error is generated, the SPSR.MODF flag can be cleared without de-asserting the pin.

When an error occurs, clear the corresponding flag of the IRQ status register (IRQSn) from within the error processing routine. If this is not done, the corresponding interrupt request flag in the IRQ status register (IRQSn) may continue to indicate a transmission buffer empty interrupt (SPTI) or reception buffer full interrupt (SPRI) request. If the reception buffer full interrupt (SPRI) request is indicated, read the reception buffer and initialize the sequencer in the RSPI.



SPEI: RSPI error interrupt
SPII: Idle interrupt
SPRI: Reception buffer full interrupt
SPTI: Transmission buffer empty interrupt

Figure 36.42 Flowchart for Slave Mode (Error Processing)

36.3.11 Clock Synchronous Operation

Setting the SPMS bit in the RSPI control register (SPCR) to 1 selects clock synchronous operation of the RSPI. In clock synchronous operation, the SSLyi pin is not used, and the three pins of RSPCKy, MOSIy, and MISOy handle communications. The SSLyi pin is available as I/O port pins.
Although clock synchronous operation does not require use of the SSLyi pin, operation of the module is the same as in SPI operation. That is, in both master and slave operations, communications can be performed with the same flow as in SPI operation. However, mode fault errors are not detected because the SSLyi pin is not used.
Furthermore, operation should not be performed if clock synchronous operation proceeds when the SPCMDm.CPHA bit is set to 0 in slave mode (SPCR.MSTR = 0).
(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

36.3.11.1 Master Mode Operation

(1) Starting a Serial Transfer

The RSPI updates the data in the transmission buffer (SPTX) of SPDR when data is written to the RSPI data register (SPDR) with the transmission buffer being empty (data for the next transfer is not set). When the shift register is empty after the number of frames set in the SPDCR.SPFC[1:0] bits are written to the SPDR, the RSPI copies data from the transmission buffer to the shift register and starts serial transmission. Upon copying transmit data to the shift register, the RSPI changes the status of the shift register to “full”, and upon termination of serial transfer, it changes the status of the shift register to “empty”. The status of the shift register cannot be referenced.
For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format.
However, transfer in clock synchronous operation is conducted without the SSLy0 output signal (y = 0, 1, 2, 3 (for all channels)).

(2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after transmitting an RSPCKy edge corresponding to the sampling timing. If free space is available in the reception buffer (SPRX), upon termination of serial transfer, the RSPI copies data from the shift register to the reception buffer of the RSPI data register (SPDR).
It should be noted that the final sampling timing varies depending on the bit length of transfer data. In master mode, the RSPI data length depends on the SPCMDm.SPB[3:0] bit setting.
For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format.
However, transfer in clock synchronous operation is conducted without the SSLy0 output signal (y = 0, 1, 2, 3 (for all channels)).

(3) Sequence Control

The transfer format employed in master mode is determined by SPSCR, SPCMDm, SPBR, SPCKD, SSLND, and SPND registers. Although the SSLyi signals are not output in clock synchronous operation, these settings are valid.
SPSCR is a register used to determine the sequence configuration for serial transfers that are executed by the RSPI in master mode. The following items are set in SPCMDm register: SSLyi output signal value, MSB/LSB first, data length, some of the bit rate settings, RSPCKy polarity/phase, whether SPCKD is to be referenced, whether SSLND is to be referenced, and whether SPND is to be referenced. SPBR holds some of the bit rate settings; SPCKD, an RSPI clock delay value; SSLND, an SSL negation delay; and SPND, a next-access delay value.
According to the sequence length that is assigned to SPSCR, the RSPI makes up a sequence comprised of a part or all of SPCMDm register. The RSPI contains a pointer to the SPCMDm register that makes up the sequence. The value of this pointer can be checked by reading the SPSSR.SPCP[2:0] bits. When the SPCR.SPE bit is set to 1 and the RSPI function is enabled, the RSPI loads the pointer to the commands in SPCMD0 register, and incorporates the SPCMD0 register setting into the transfer format at the beginning of serial transfer. The RSPI increments the pointer each time the next-access delay period for a data transfer ends. Upon completion of the serial transfer that corresponds to the final command comprising the sequence, the RSPI sets the pointer in SPCMD0 register, and in this manner the sequence is executed repeatedly.
(i = 0 to 3; m = 0 to 7; y = 0, 1, 2, 3 (for all channels))

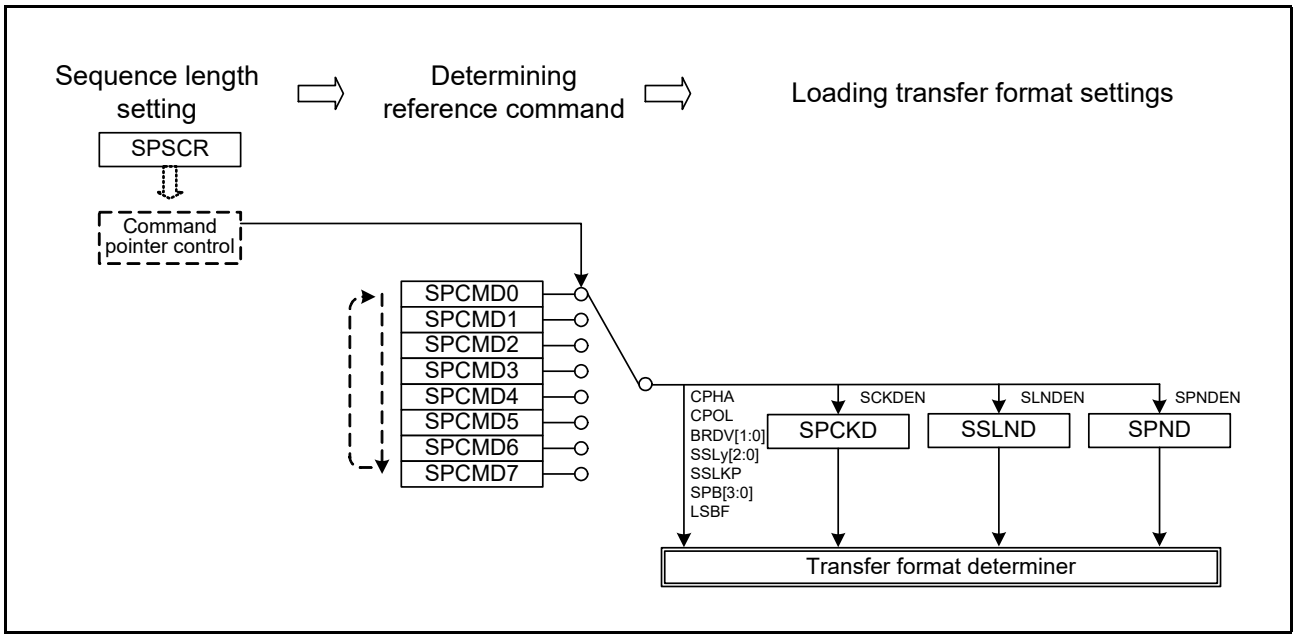


Figure 36.43 Procedure for Determining the Form of Serial Transmission in Master Mode

In this section, a frame is the combination of the data (SPDR) and the settings (SPCMDm) (m = 0 to 7).

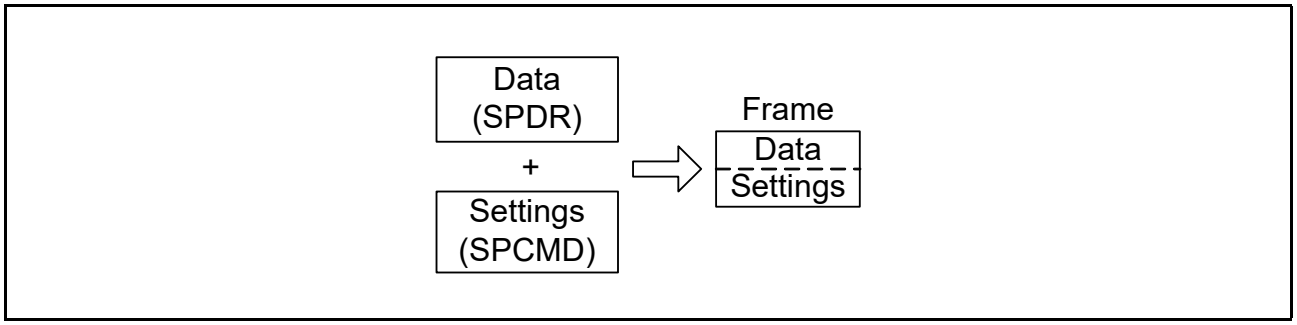

Figure 36.44 Concept of a Frame

Figure 36.45 shows the relationship between the command and the transmit and reception buffers in the sequence of operations specified by the settings in Table 36.4.

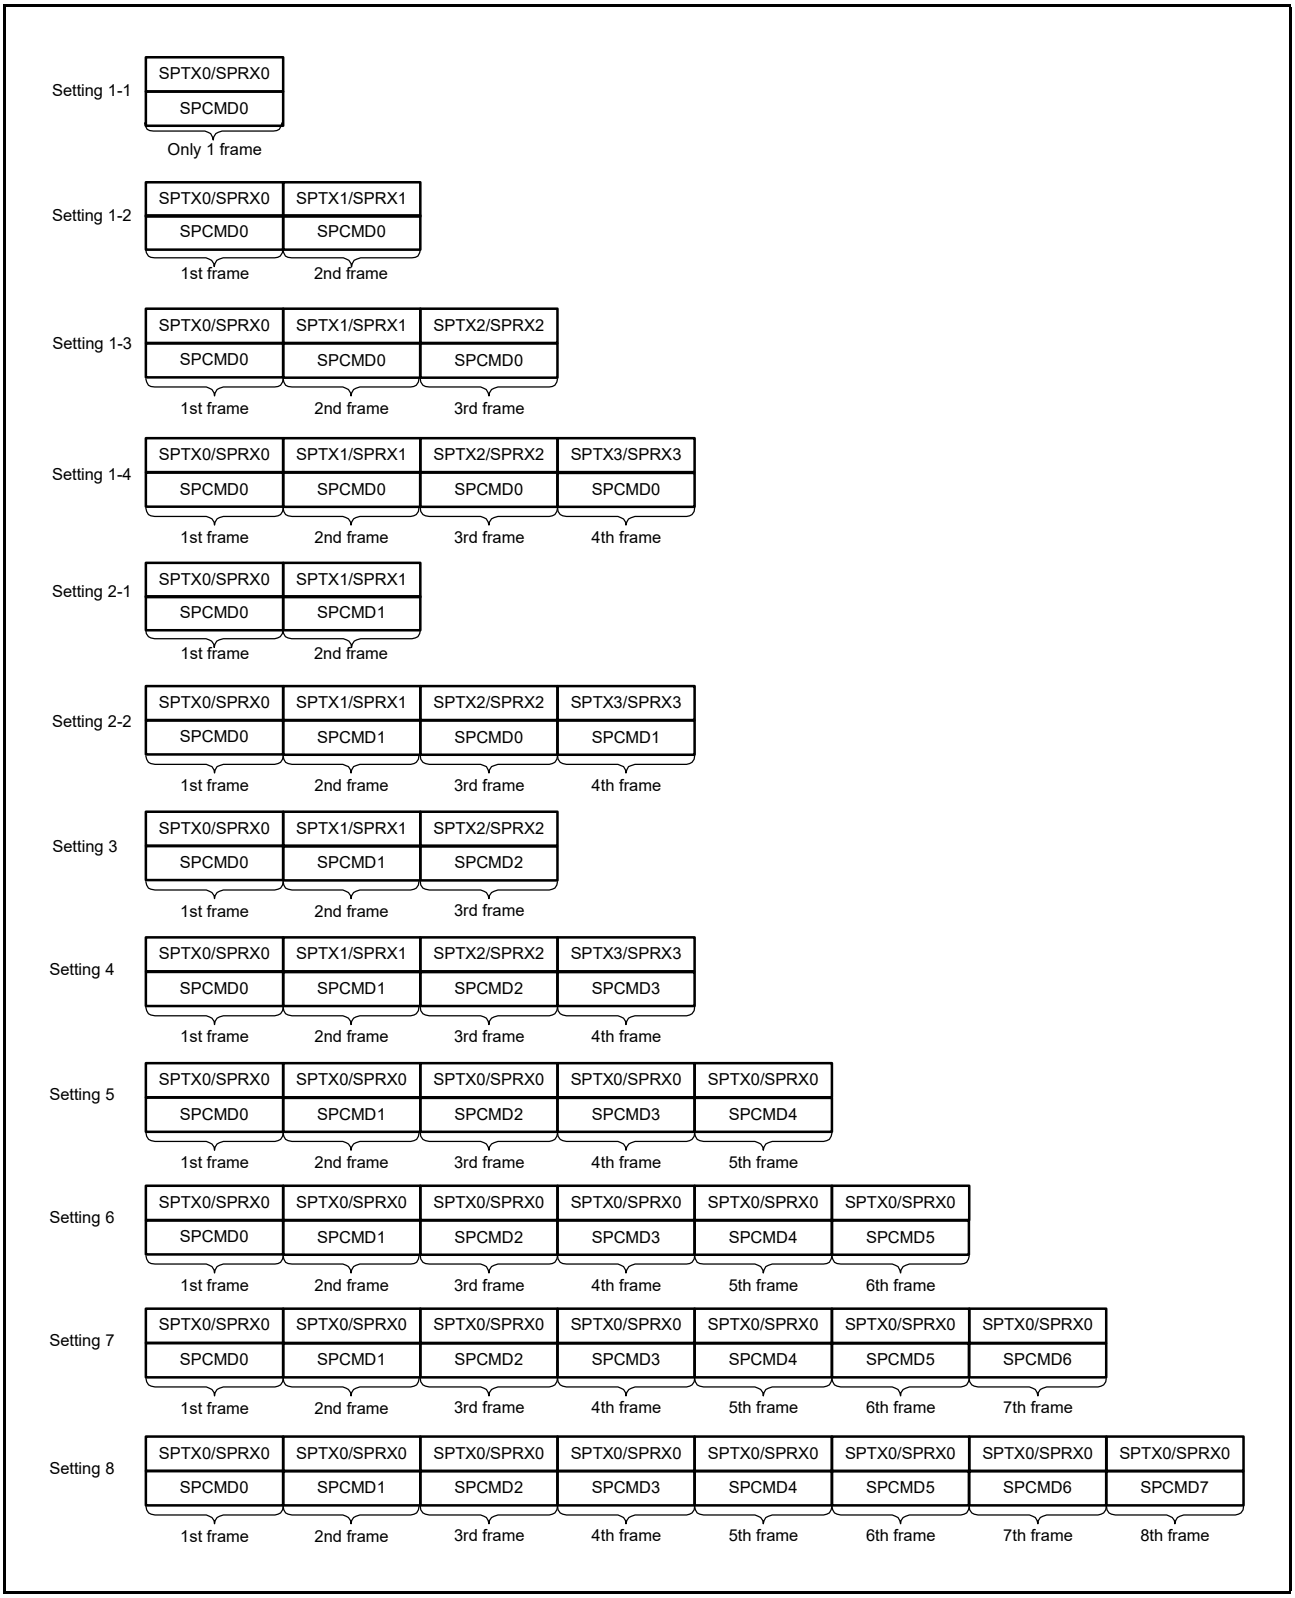

Figure 36.45 Correspondence between the RSPI Command Register and Transmission/Reception Buffers in Sequence Operations

(4) Initialization Flowchart

Figure 36.46 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in master mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

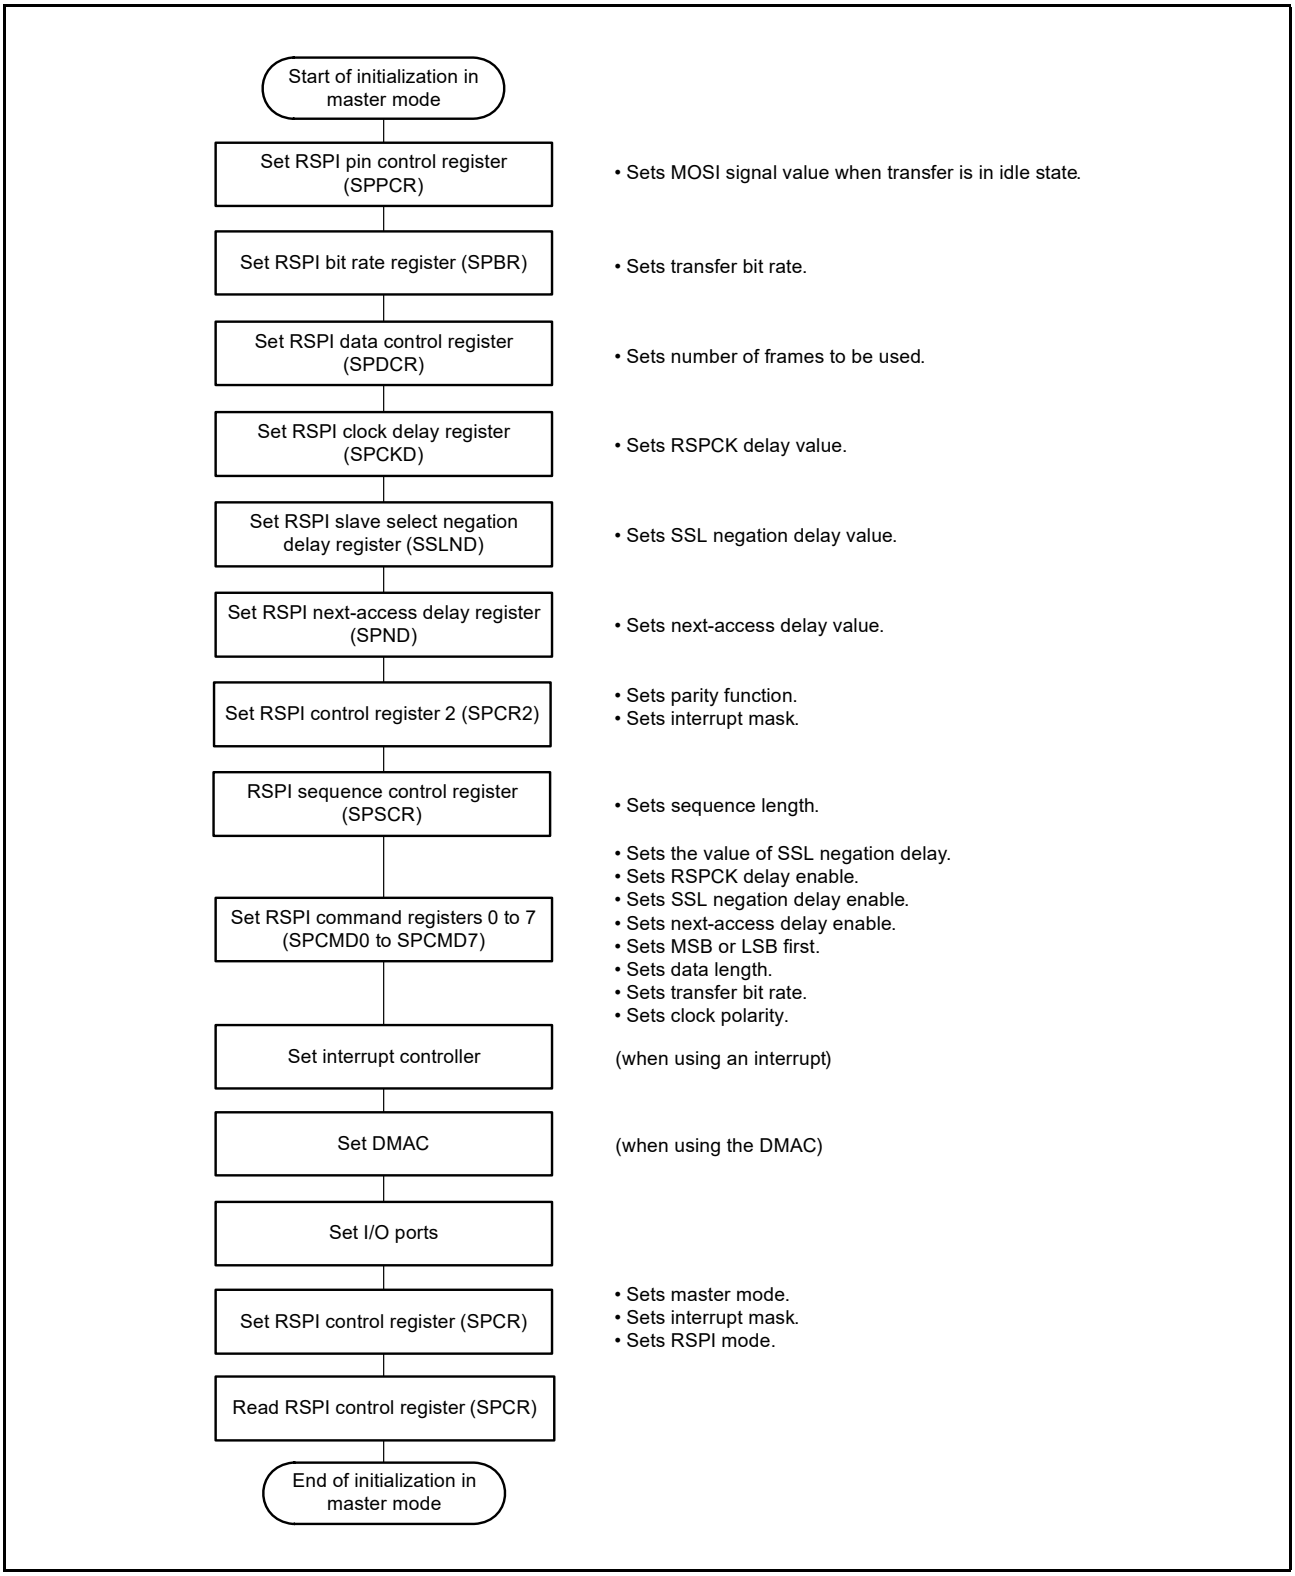

Figure 36.46 Example of Initialization Flowchart in Master Mode (Clock Synchronous Operation)

(5) Flow of Software Processing

Software processing during clock-synchronous master operation is the same as that for SPI master operation. For details, refer to section 36.3.10.1, (9) Software Processing Flow. Note that mode-fault errors will not occur.

36.3.11.2 Slave Mode Operation

(1) Starting a Serial Transfer

When the SPCR.SPMS bit is 1, the first RSPCKy edge triggers the start of a serial transfer in the RSPI.
When detecting the start of a serial transfer in a condition in which the shift register is empty, the RSPI changes the status of the shift register to “full”, so that data cannot be copied from the transmission buffer to the shift register when serial transfer is in progress. If the shift register was full before the serial transfer started, the RSPI keeps the status of the shift register unchanged, in the full state.
When the SPMS bit is 1, the RSPI always drives the MISOy output signal.
For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format.
It should be noted that the SSL0 input signal is not used in clock synchronous operation (y = 0, 1, 2, 3 (for all channels)).

(2) Terminating a Serial Transfer

The RSPI terminates the serial transfer after detecting an RSPCKy edge corresponding to the final sampling timing. When free space is available in the reception buffer, upon termination of serial transfer the RSPI copies received data from the shift register to the reception buffer of the RSPI data register (SPDR). Upon termination of a serial transfer the RSPI changes the status of the shift register to “empty”. The final sampling timing changes depending on the bit length of transfer data. In slave mode, the RSPI data length depends on the SPCMD0.SPB[3:0] bit setting. For details on the RSPI transfer format, refer to section 36.3.5, Transfer Format. (y = 0, 1, 2, 3 (for all channels))

(3) Initialization Flowchart

Figure 36.47 is a flowchart illustrating an example of initialization in clock synchronous operation when the RSPI is used in slave mode. For a description of how to set up the interrupt controller, DMAC, and I/O ports, refer to the descriptions given in the individual blocks.

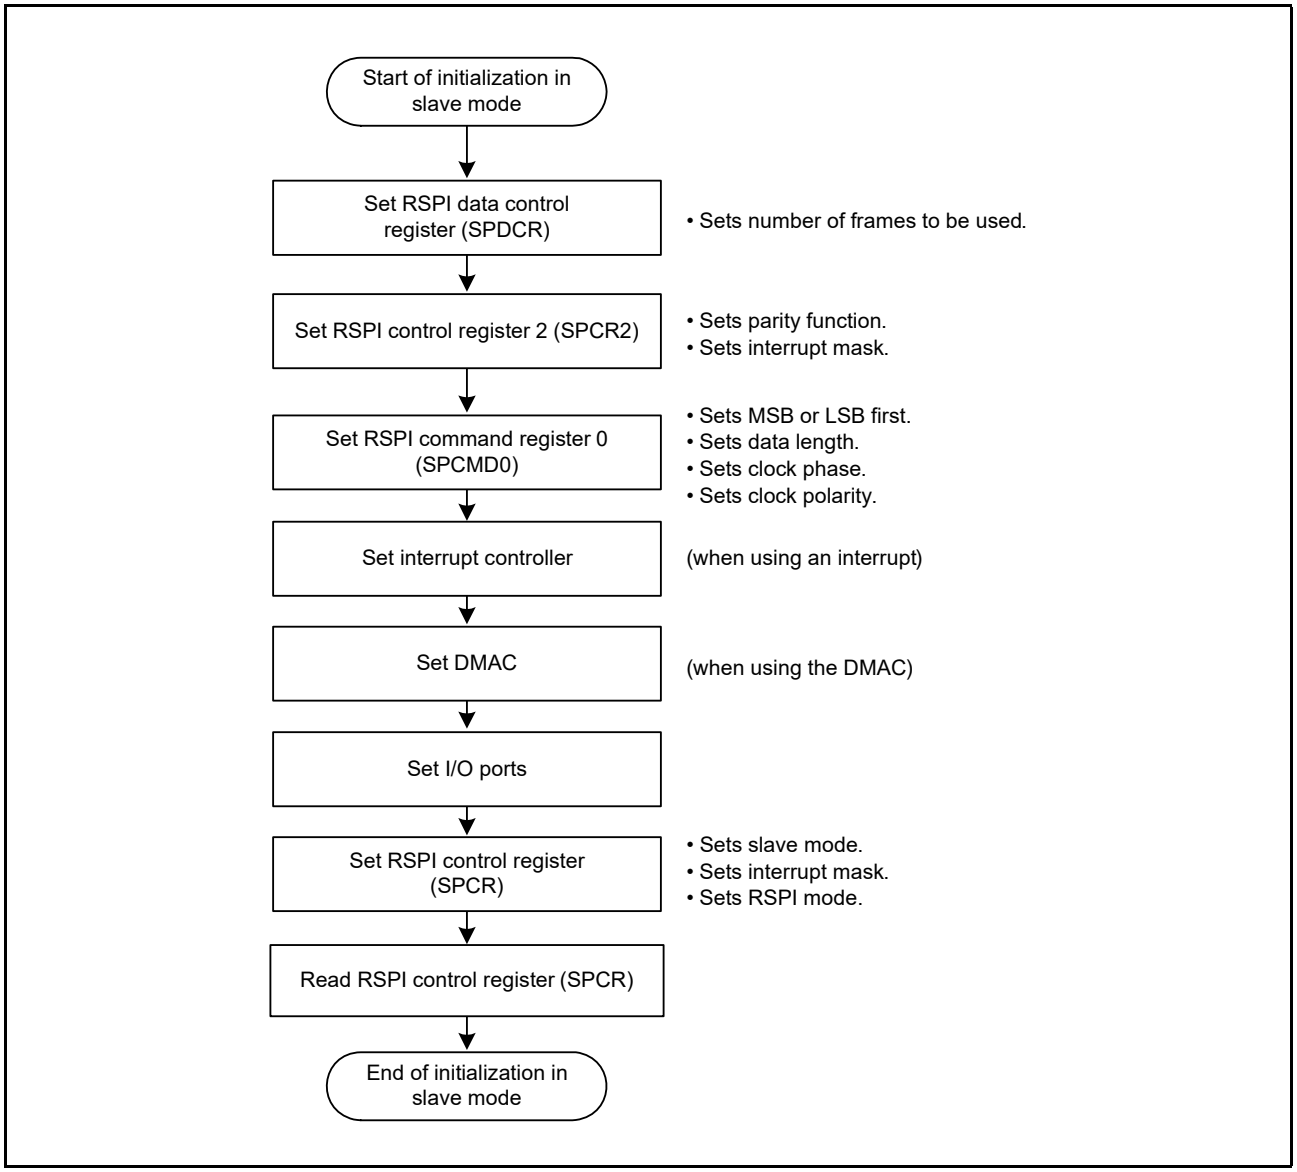

Figure 36.47 Example of Initialization Flowchart in Slave Mode (Clock Synchronous Operation)

(4) Flow of Software Processing

Software processing during clock-synchronous slave operation is the same as that for SPI slave operation. For details, refer to section 36.3.10.2, (6) Software Processing Flow. Note that mode-fault errors will not occur.

36.3.12 Loopback Mode

When 1 is written to the SPPCR.SPLP2 bit or SPPCR.SPLP bit, the RSPI shuts off the path between the MISOy pin and the shift register if the SPCR.MSTR bit is 1, and between the MOSIy pin and the shift register if the SPCR.MSTR bit is 0, and connects the input path and output path of the shift register. The RSPI does not shut off the path between the MOSIy pin and the shift register if the SPCR.MSTR bit is 1, and between the MISOy pin and the shift register if the SPCR.MSTR bit is 0. This is called loopback mode. When a serial transfer is executed in loopback mode, the transmit data for the RSPI or the inversed transmit data becomes the received data for the RSPI.
Table 36.12 lists the relationship among the SPLP2 and SPLP bits and the received data. Figure 36.48 shows the configuration of the shift register I/O paths for the case where the RSPI in master mode is set in loopback mode (SPPCR.SPLP2 = 0, SPPCR.SPLP = 1) (y = 0, 1, 2, 3 (for all channels)).

Table 36.12 SPLP2 and SPLP Bit Settings and Received Data

SPPCR.SPLP2 Bit	SPPCR.SPLP Bit	Received Data
0	0	Input data from the MOSIy pin or MISOy pin
0	1	Inversed transmit data
1	0	Transmit data
1	1	Transmit data

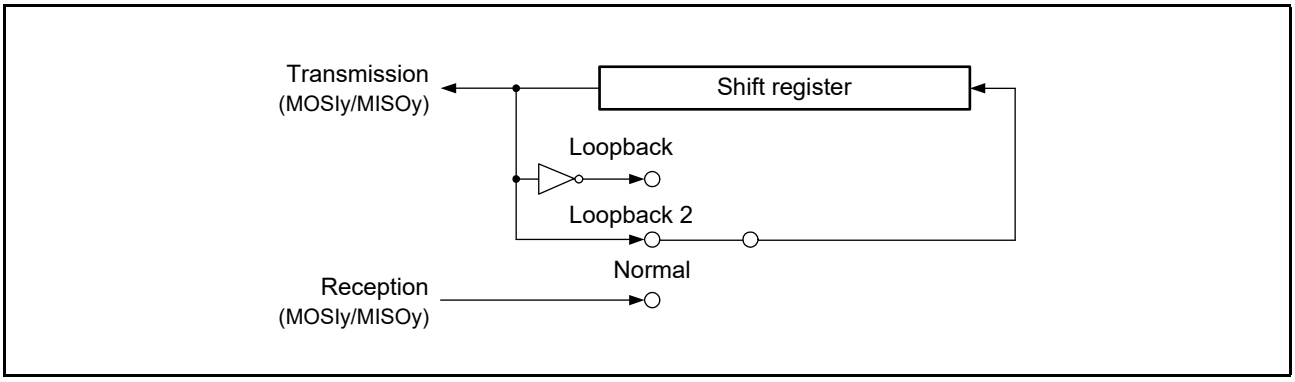

Figure 36.48 Configuration of Shift Register I/O Paths in Loopback Mode (Master Mode)

36.3.13 Self-Diagnosis of Parity Bit Function

The parity circuit consists of a parity bit adding unit used for transmit data and an error detecting unit used for received data. In order to detect defects in the parity bit adding unit and error detecting unit of the parity circuit, self-diagnosis is executed for the parity circuit following the flowchart shown in Figure 36.49.

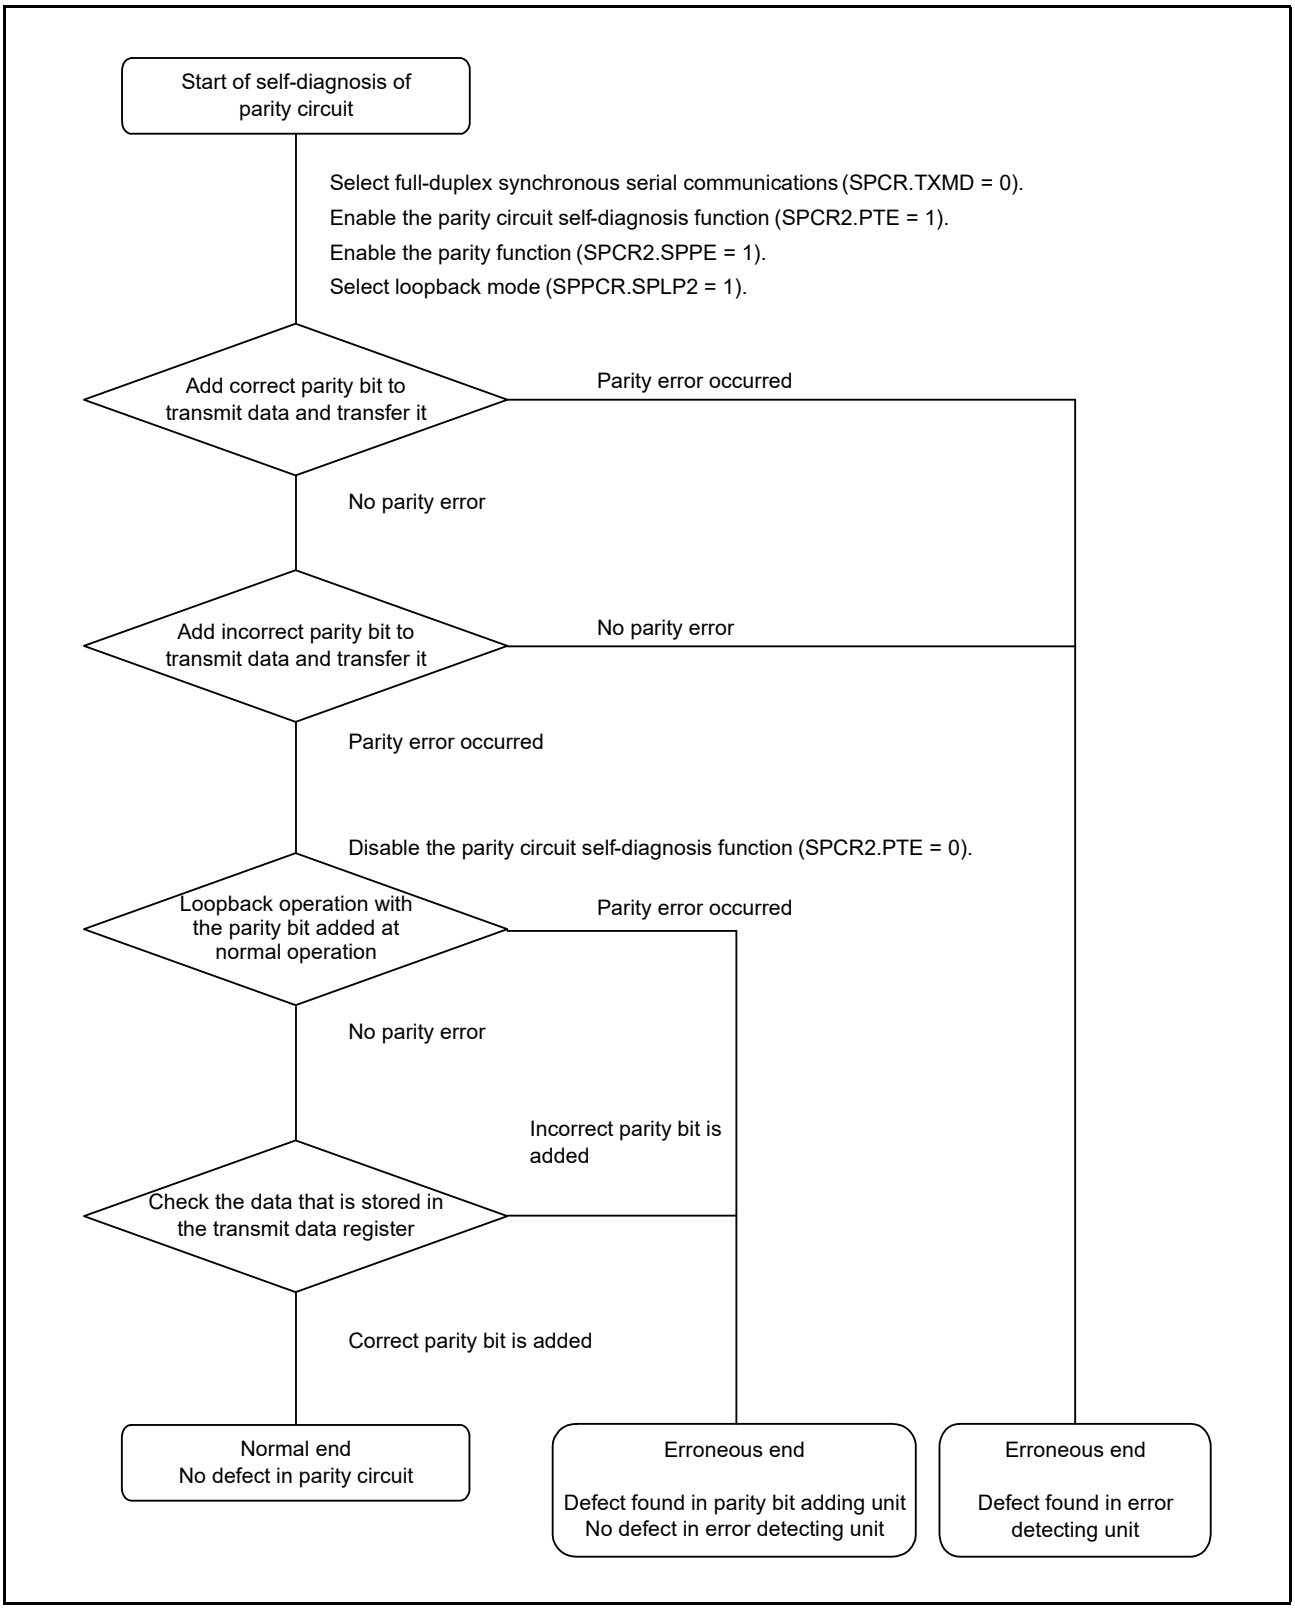

Figure 36.49 Flowchart for Self-Diagnosis of Parity Circuit

36.3.14 Interrupt Sources

The RSPI has interrupt sources of reception buffer full, transmission buffer empty, mode fault, overrun, parity error, and RSPI idle. In addition, the DMAC can be activated by the reception buffer full or transmission buffer empty interrupt to perform data transfer.

Since the common vector address is allocated to interrupt requests due to mode-fault, overrun, and parity errors, the actual interrupt source must be determined from the flags. Interrupt sources for the RSPI are listed in Table 36.13. An interrupt is generated on satisfaction of an interrupt condition in Table 36.13. Clear the reception buffer full and transmission buffer empty sources through data transfer.

When using the DMAC to perform data transmission/reception, the DMAC must be set up first to be in a status in which transfer is enabled before making the RSPI settings. For the method for setting the DMAC, refer to section 15, DMA Controller (DMACAa).

Table 36.13 Interrupt Sources of RSPI

Interrupt Source	Symbol	Interrupt Condition	DMAC/DTC Activation
Reception buffer full	SPRI	The reception buffer becomes full while the SPCR.SPRIE bit is 1.	Possible
Transmission buffer empty	SPTI	The transmission buffer becomes empty while the SPCR.SPTIE bit is 1.	Possible
RSPI errors (mode fault, overrun and parity error)	SPEI	The SPSR.MODF, OVRF, or PERF flag is set to 1 while the SPCR.SPEIE bit is 1.	Impossible
RSPI idle	SPII	The SPSR.IDLNF flag is set to 0 while the SPCR2.SPIIE bit is 1.	Impossible

36.4 Link Operation by Event Linking (only for RSPI channel 0)

The event link controller (ELC) is capable of producing the following event output signals. The event link output signal is output regardless of the setting of the corresponding interrupt enable bit (SPCR.SPEIE, SPCR.SPTIE or SPCR.SPRIE).

36.4.1 Reception Buffer Full Event Output

This event signal is output when received data have been transferred from the shift register to the SPDR on completion of serial transfer.

36.4.2 Transmission Buffer Empty Event Output

This event signal is output when data for transmission have been transferred from the transmission buffer to the shift register and when the value of the SPE bit has changed from 0 to 1.

36.4.3 Mode Fault, Overrun, or Parity Error Event Output

(1) Mode Fault

Table 36.14 lists the occurrence conditions of a mode fault event.

Table 36.14 Occurrence Conditions of Mode Fault Event

	SPCR.MODFEN Bit	SSLy0 Pin (y = 0, 1, 2, 3)	Remarks
Master (SPCR.MSTR bit = 1)	1	Active	When the setting of the SPCR.SPMS bit is 0 while the MSTR and SPCR.MODFEN bits are 1, mode fault error, overrun error, and parity error event output cannot be used. Do not set the ELSRn register to 52h.
Slave (SPCR.MSTR bit = 0)	1	Not active	Event is output only when the pin is deactivated during transmission.

(2) Overrun

The condition for this event signal being output in response to an overrun is completion of serial transfer while the reception buffer contains data that have not been read and the value of the SPCR.TXMD bit is 0, in which case the OVRF flag is set to 1.

(3) Parity Error

The condition for this event signal being output in response to a parity error is detection of a parity error on completion of serial transfer while the value of the TXMD bit in SPCR is 0 and the value of the SPPE bit in SPCR2 is 1.

36.4.4 RSPI Idle Event Output

(1) In Master Mode

In master mode, an event is output when the condition for setting the IDLNF flag (RSPI idle flag) to 0 is satisfied.

(2) In Slave Mode

In slave mode, an event is output when the SPE bit in the SPCR is set to 0 (RSPI is initialized).

36.4.5 Transmission-Completed Event Output

During both SPI operation and clock synchronous operation in master mode, an event is output under the condition for setting the IDLNF flag (RSPI idle flag) from 1 to 0.

Table 36.15 Conditions for Generation of a Transmission-Completed Event (Slave)

	Transmission Buffer State	Shift Register State	Others
SPI operation (SPCR.SPMS = 0)	Empty	Empty	Negation of SSL0 input
Clock synchronous operation (SPCR.SPMS = 1)	Empty	Empty	Edge detection of the last RSPCK

Regardless of whether the operation is in master mode or slave mode, an event is not output if 0 is written to the SPCR.SPE bit in transmission or the SPCR.SPE bit is cleared because of a mode fault error.

36.5 Usage Notes

36.5.1 Setting Module Stop Function

Module stop control register B (MSTPCRB) is used to enable or disable operation of the RSPI. The RSPI is stopped after a reset. The registers become accessible on release from the module-stop state. For details, refer to section 9, Low-Power Consumption Function.

36.5.2 Note on Low-Power Consumption Functions

Set the SPCR.SPE bit to 0 and terminate communications prior to entering module-stop state.

36.5.3 Notes on Starting Transfer

If the corresponding interrupt request flag in the IRQ status register (IRQSn) is 1 at the time transfer is to be started, the next interrupt request is generated after the start of transfer and an interrupt request is retained in the module. This can lead to unanticipated behavior of the interrupt request flag.
When the request flag for the RSPI interrupt request is 1 at the time transfer is to start, follow the procedure below to clear interrupt requests in the module or the IRQ status register (IRQSn) before enabling operations (by setting the SPCR.SPE bit to 1).

1. Confirm that transfer has stopped (i.e. that the SPCR.SPE bit is 0).
2. Set the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) to 0.
3. Read the relevant interrupt enable bit (the SPCR.SPTIE or SPCR.SPRIE bit) and confirm that its value is 0.
4. Set the relevant interrupt request flag in the IRQ status register (IRQSn) to 0.

37. SPI Multi I/O Bus Controller (SPIBSC)

The SPI multi I/O bus controller outputs control signals to the serial flash memory connected to the SPI multi I/O bus space, thus enabling direct connection of the serial flash memory.
This LSI incorporates one channel of SPI multi I/O bus controller.

37.1 Overview

This module allows using direct reading or SPI operating mode to transmit and receive data with the serial flash memory connected to the SPI multi I/O bus space. The specification of the SPIBSC is listed in Table 37.1.

Table 37.1 SPIBSC Specifications

Item	Description
Serial flash interface	• One serial flash memory can be connected. • A data bus size of 1 bit, 2 bits, or 4 bits can be selected.
External address space read mode	• A maximum of 4 Gbytes of address space is supported. • The SPBSSL pin can be automatically controlled by access address monitoring. • Efficient data reception is possible due to the internal read cache (line size: 64 bits × 16 entries).
SPI operating mode	• Any read and write operations are available for a serial flash memory.
Bit rate	• The internal baud rate generator divides the frequency of PCLKA to generate SPBCLK. • The frequency division ratio of SPBCLK can be set in the range from 2 to 4080.
SPBSSL pin control	• The delay from the time the SPBSSL signal is activated to the time SPBCLK starts operating (clock delay) can be set. Setting range: 1 to 8 SPBCLK; Unit of the setting: 1 SPBCLK • The delay from the time SPBCLK stops to the time the SPBSSL output is inactivated (SPBSSL negation delay) can be set. Setting range: 1.5 to 8.5 SPBCLK; Unit of the setting: 1 SPBCLK • The wait of the SPBSSL output for the next access (next access delay) can be set. Setting range: 1 to 8 SPBCLK; Unit of the setting: 1 SPBCLK • The polarity of the SPBSSL signal can be changed.

Figure 37.1 is a block diagram of this module.

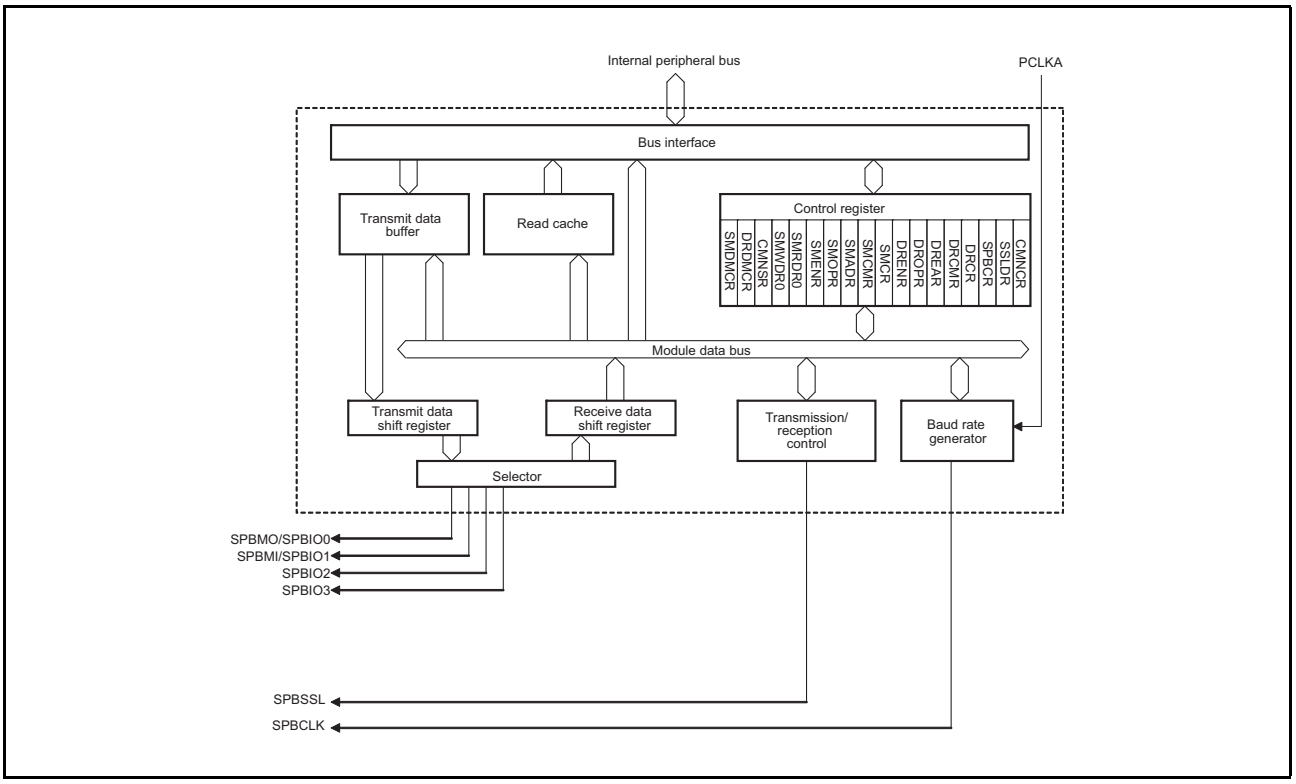

Figure 37.1 Block Diagram of SPIBSC

Table 37.2 lists the input/output pins of this module.

Table 37.2 Pin Configuration of the SPIBSC

Pin Name	Symbol	I/O	Function
Clock pin	SPBCLK	Output	Clock output
Slave select pin	SPBSSL	Output	Slave selection
Port data 0 pin	SPBMO/SPBIO0	I/O	Port master transmit data/data 0
Port data 1 pin	SPBMI/SPBIO1	I/O	Port master input data/data 1
Port data 2 pin	SPBIO2	I/O	Port data 2
Port data 3 pin	SPBIO3	I/O	Port data 3

37.2 Register Descriptions

37.2.1 Common Control Register (CMNCR)

The CMNCR register is a 32-bit register that controls the SPI multi I/O bus controller. The settings of this register are reflected both in external address space read mode and SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Value after reset:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	BSZ[1:0]	Data Bus Size	Specifies the number of serial flash memories to be connected. This bit must be set to 00b because only one memory can connect to this product. If another value is set, the operation cannot be guaranteed. b1 b0 0 0: 1 memory 0 1: Setting prohibited 1 X: Setting prohibited	R/W
b2	—	Reserved	This bit is always read as 0. The write value should always be 0.	R/W
b3	CPOL	SPBSSL Negation Period SPBCLK Output Direction	Sets the output level of the SPBCLK pin during inactive period of the SPBSSL signal. 0: The output of the SPBCLK pin is 0 during inactive period of the SPBSSL signal. 1: The output of the SPBCLK pin is 1 during inactive period of the SPBSSL signal.	R/W
b4	SSLP	SPBSSL Signal Polarity	Sets the polarity of SPBSSL signal. 0: Active low SPBSSL signal 1: Active high SPBSSL signal	R/W
b5	CPHAR	Input Latch	Sets the edge of the SPBCLK signal for the reception data. The CPHAT bit and this bit should be set according to the following table. 0: Data reception at odd edge 1: Data reception at even edge Settings of the CPHAT and CPHAR Bits CPHAT / CPHAR: 0/0 Setting enabled; 0/1 Setting enabled; 1/0 Setting prohibited; 1/1 Setting enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b6	CPHAT	Output Shift	Sets the edge of the SPBCLK signal for data transmission. This bit and the CPHAR bit should be set according to the description of the CPHAR bit. 0: Data transmission at even edge 1: Data transmission at odd edge	R/W
b7	—	Reserved	This bit is always read as 0. The write value should always be 0.	R/W
b9, b8	IO0FV[1:0]	SPBIO0 Fixed Value for 1-bit Size Input	Fixes the output value of the SPBIO0 pins for 1-bit size input. b9 b8 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W
b11, b10	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b13, b12	IO2FV[1:0]	SPBIO2 Fixed Value for 1-bit/2-bit Size	Fixes the output value of the SPBIO2 pins for 1-bit/2-bit size. b13 b12 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W
b15, b14	IO3FV[1:0]	SPBIO3 Fixed Value for 1-bit/2-bit Size	Fixes the output value of the SPBIO3 pins for 1-bit/2-bit size. b15 b14 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W
b17, b16	MOIIO0[1:0]	SPBIO0 Fixed Value for SPBSSL Idle	Fixes output values of the SPBIO0 pins during inactive period of the SPBSSL signal. b17 b16 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W
b19, b18	MOIIO1[1:0]	SPBIO1 Fixed Value for SPBSSL Idle	Fixes output values of the SPBIO1 pins during inactive period of the SPBSSL signal. b19 b18 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W
b21, b20	MOIIO2[1:0]	SPBIO2 Fixed Value for SPBSSL Idle	Fixes output values of the SPBIO2 pins during inactive period of the SPBSSL signal. b21 b20 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W

Bit	Symbol	Bit Name	Description	R/W
b23, b22	MOIIO3[1:0]	SPBIO3 Fixed Value for SPBSSL Idle	Fixes output values of the SPBIO3 pins during inactive period of the SPBSSL signal. b23 b22 0 0: Output value 0 0 1: Output value 1 1 0: Output value is the last bit value of the previous transfer (or the state is Hi-Z, if Hi-Z was the state in the last bit period of the previous transfer). 1 1: Output value Hi-Z	R/W
b24	SFDE	Data Swap Setting for Serial Flash Memory	Specifies whether or not swapping of data in serial flash memory is performed. 0: Swapping is not performed. 1: Swapping is performed in 8-bit units. For details, see section 37.3.4, Data Alignment.	R/W
b30 to b25	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b31	MD	Operating Mode Switch	Switches the operating modes. 0: External address space read mode 1: SPI operating mode	R/W

37.2.2 SSL Delay Register (SSLDR)

The SSLDR register is a 32-bit register that adjusts the timing between the SPBSSL signal and the SPBCLK signal. The settings of this register are reflected both in external address space read mode and SPI operating mode.
The settings of this register should be changed when the TEND flag in the CMNSR register is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5004h

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	SCKDL[2:0]	Clock Delay	Sets the period from the time the SPBSSL signal is activated to the time the clock is output from the SPBCLK signal (clock delay). b2 b0 000: 1 SPBCLK cycle 001: 2 SPBCLK cycles 010: 3 SPBCLK cycles 011: 4 SPBCLK cycles 100: 5 SPBCLK cycles 101: 6 SPBCLK cycles 110: 7 SPBCLK cycles 111: 8 SPBCLK cycles	R/W
b7 to b3	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b10 to b8	SLNDL[2:0]	SPBSSL Negation Delay	Sets the period from the time the last edge of the SPBCLK signal is transferred to the time the SPBSSL signal is inactivated (SPBSSL negation delay). b10 b8 000: 1.5 SPBCLK cycles 001: 2.5 SPBCLK cycles 010: 3.5 SPBCLK cycles 011: 4.5 SPBCLK cycles 100: 5.5 SPBCLK cycles 101: 6.5 SPBCLK cycles 110: 7.5 SPBCLK cycles 111: 8.5 SPBCLK cycles	R/W
b15 to b11	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b18 to b16	SPNDL[2:0]	Next Access Delay	Sets the period from transfer end to next transfer start (next access). b18 b16 000: 1 SPBCLK cycle 001: 2 SPBCLK cycles 010: 3 SPBCLK cycles 011: 4 SPBCLK cycles 100: 5 SPBCLK cycles 101: 6 SPBCLK cycles 110: 7 SPBCLK cycles 111: 8 SPBCLK cycles	R/W
b31 to b19	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.3 Bit Rate Register (SPBCR)

The SPBCR register is a 32-bit register that sets the bit rate.
The settings of this register are reflected both in external address space read mode and SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5008h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	SPBR[7:0]								—	—	—	—	—	—	BRDV[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1

Bit	Symbol	Bit Name	Description	R/W
b1, b0	BRDV[1:0]	Bit Rate Frequency Division	Sets the bit rate. The bit rate is determined by a combination of these bits with the SPBR[7:0] bits. The setting value of the SPBR bit determines the base bit rate. This bit is used to select a division ratio of the base bit rate from among no division, 2, 4, and 8. b1 b0 0 0: Base bit rate 0 1: Base bit rate divided by 2 1 0: Base bit rate divided by 4 1 1: Base bit rate divided by 8	R/W
b7 to b2	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b15 to b8	SPBR[7:0]	Bit Rate	Sets the bit rate. The bit rate is determined by a combination of these bits with the BRDV[1:0] bits. For details, see Table 37.3, Relationship between SPBR[7:0] and BRDV[1:0] Settings.	R/W
b31 to b16	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

(1) Bit Rate

The SPBR[7:0] and BRDV[1:0] bits are used for setting the bit rate.
The following formula is used to calculate the bit rate when SPBR[7:0] ≠ 0:

Bit rate = PCLKA / $(2 \times n \times 2^N)$

n: SPBR[7:0] setting (1, …, 255)
N: BRDV[1:0] setting (0 to 3)

The following formula is used to calculate the bit rate when SPBR[7:0] = 0:

Bit rate = PCLKA / 2^N

Setting both the SPBR[7:0] and BRDV[1:0] bits to 0 is prohibited.

Table 37.3 Relationship between SPBR[7:0] and BRDV[1:0] Settings

SPBR[7:0] (n)	BRDV[1:0] (N)	Division Ratio	Bit Rate PCLKA = 150 MHz
0	0	1	Setting prohibited
0	1	2	75 Mbps
0	2	4	37.5 Mbps
0	3	8	18.75 Mbps
1	0	2	75 Mbps
2	0	4	37.5 Mbps
3	0	6	25 Mbps
4	0	8	18.75 Mbps
5	0	10	15 Mbps
6	0	12	12.5 Mbps
6	1	24	6.25 Mbps
6	2	48	3.13 Mbps
6	3	96	1.56 Mbps
255	3	4080	36.76 Kbps

Note: The bit rate should be set so that it will satisfy the AC characteristics of this module.

37.2.4 Data Read Control Register (DRCR)

The DRCR register is a 32-bit register that sets the operation in external address space read mode.
The bits except the SSLN bit should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 500Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	SSLN	—	—	—	—	RBURST[3:0]			
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	RCF	RBE	—	—	—	—	—	—	—	SSLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SSLE	SPBSSL Negation	Sets the inactivation conditions for the SPBSSL signal during read burst. The SPBSSL signal is inactivated for each access during normal read. 0: The SPBSSL signal is inactivated after transfer of data set in burst length. 1: The SPBSSL signal is inactivated when the accessed address is not continuous with the previously transferred address.	R/W
b7 to b1	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b8	RBE	Read Burst	Turns burst read ON or OFF. 0: Data is read according to the access size. 1: Read cache is enabled, and as many data units as the burst count specified in RBURST[3:0] bits is read.	R/W
b9	RCF	Read Cache Flush	When 1 is written to this bit, all the entries in the read cache are cleared. This bit is always read as 0. Note: After flushing the read cache by writing 1 to this bit, read the DRCR register before proceeding to read from the external address space.	R/W
b15 to b10	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b19 to b16	RBURST [3:0]	Read Data Burst Length	Sets the burst length (data unit count) when reading. This bit is enabled when the RBE bit of this register is set to 1. b19 b16 0000: 1 data unit 0001: 2 continuous data units : 1110: 15 continuous data units 1111: 16 continuous data units One data unit is 64 bits long.	R/W
b23 to b20	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b24	SSLN	SPBSSL Negation	Writing 1 to this bit when both the RBE and SSLE bits of this register are 1 inactivates the active SPBSSL signal. This bit is always read as 0. Note: To start next access after the SPBSSL signal is inactivated by this bit, read the SSLF bit of the CMNSR register = 0 to confirm that the SPBSSL signal has been inactivated.	R/W

Bit	Symbol	Bit Name	Description	R/W
b31 to b25	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.5 Data Read Command Setting Register (DRCMR)

The DRCMR register is a 32-bit register that sets the commands issued in external address space read mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	OCMD[7:0]	Optional Command	Sets the optional command.	R/W
b15 to b8	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b23 to b16	CMD[7:0]	Command	Sets the command. For details, see the details about the serial flash memory to be used.	R/W
b31 to b24	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.6 Data Read Extended Address Setting Register (DREAR)

The DREAR register is an address setting register when the serial flash address is output in 32-bit mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	EAV[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	EAC[2:0]		
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b2 to b0	EAC[2:0]	32-Bit Extended External Address Valid Range	Sets the range of the external address to be used as serial flash address when the serial flash address is output in 32-bit mode. This setting is valid when the ADE[3] bit in DRENR is 1. b2 b0 000: External address bits [24:0] enabled 001: External address bits [25:0] enabled Other than above: Setting prohibited	R/W
b15 to b3	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b23 to b16	EAV[7:0]	32-Bit Extended Upper Address Fixed Value	The upper address of the external address specified by the EAC[2:0] bits of this register are set to these bits when the serial flash address is output in 32-bit mode. Bit 0 corresponds to the serial flash address bit [25], and bit 7 corresponds to the bit [32]. This setting is valid only when the ADE[3] bit in DRENR is 1. When EAC[2:0] are 000, serial flash address [32:25] are set to EAV[7:0]. When EAC[2:0] are 001, serial flash address [32:26] are set to EAV[7:1].	R/W
b31 to b24	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.7 Data Read Option Setting Register (DROPR)

The DROPR register is a 32-bit register that sets the option data in external address space read mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	OPD0[7:0]	Option Data 0	Sets the option data 0.	R/W
b15 to b8	OPD1[7:0]	Option Data 1	Sets the option data 1.	R/W
b23 to b16	OPD2[7:0]	Option Data 2	Sets the option data 2.	R/W
b31 to b24	OPD3[7:0]	Option Data 3	Sets the option data 3.	R/W

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

37.2.8 Data Read Enable Setting Register (DRENR)

The DRENR register is a 32-bit register that sets the bit size of the command, optional command, address, option data, and read data in external address space read mode and enables outputting them other than read data.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 501Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	1	0	0	0	1	1	1	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b7 to b4	OPDE[3:0]	Option Data Enable	Sets the option data to be output. Be sure to use the following setting; otherwise, the operation is not guaranteed. b7 b4 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited	R/W
b11 to b8	ADE[3:0]	Address Enable	Sets the address to be output. Be sure to use the following setting; otherwise, the operation is not guaranteed. b11 b8 0000: Output disabled 0111: Address[23:0] 1111: Address[31:0] Other than above: Setting prohibited	R/W
b12	OCDE	Optional Command Enable	Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled	R/W
b13	—	Reserved	This bit is always read as 0. The write value should always be 0.	R/W
b14	CDE	Command Enable	Sets the command to be output. 0: Command output disabled 1: Command output enabled	R/W
b15	DME	Dummy Cycle Enable	Enables insertion of the dummy cycle before the read data. Note: A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled	R/W
b17, b16	DRDB[1:0]	Data Read Bit Size	Sets the data read size in bit units. b17 b16 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W

Bit	Symbol	Bit Name	Description	R/W
b19, b18	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b21, b20	OPDB[1:0]	Option Data Bit Size	Sets the option data size in bit units. b21 b20 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b23, b22	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b25, b24	ADB[1:0]	Address Bit Size	Sets the address size in bit units. b25 b24 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b27, b26	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b29, b28	OCDB[1:0]	Optional Command Bit Size	Sets the optional command size in bit units. b29 b28 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b31, b30	CDB[1:0]	Command Bit Size	Sets the command size in bit units. For details, see the details about the serial flash memory to be used. b31 b30 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W

37.2.9 SPI Mode Control Register (SMCR)

The SMCR register is a 32-bit register that sets the operation in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	SSLKP	—	—	—	—	—	SPIRE	SPIWE	SPIE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	SPIE	SPI Data Transfer Enable	Data is transferred by setting this bit to 1. This bit is enabled only when the TEND bit in CMNSR is set to 1. The operation cannot be guaranteed when this bit is set to 1 with the TEND bit set to 0. This bit is always read as 0. Note: When the SPBSSL signal is inactive, the command, optional command, address, and option data that are set as the output by the DRENR register are output even if the SPIRE and SPIWE bits are set to 0. When the SPBSSL signal is active, follow the notes described in section 37.4.2, Notes on Starting Transfer from the SPBSSL Signal Retained State in SPI Operating Mode.	R/W
b1	SPIWE	Data Write Enable	Sets write operation in SPI operating mode. 0: Data writing disabled 1: Data writing enabled Note: When the transfer data bit size is set to 2 bits or 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.	R/W
b2	SPIRE	Data Read Enable	Sets read operation in SPI operating mode. 0: Data reading disabled 1: Data reading enabled Note: When the transfer data bit size is set to 2 bits or 4 bits with the SPIDB[1:0] bits, the SPIRE and SPIWE bits should not be set to 1 at the same time.	R/W
b7 to b3	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b8	SSLKP	SPBSSL Signal Level	Determines the status of the SPBSSL signal after the end of transfer. 0: SPBSSL signal is inactivated at the end of transfer. 1: SPBSSL signal level is maintained from the end of transfer to the start of next access.	R/W
b31 to b9	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.10 SPI Mode Command Setting Register (SMCMR)

The SMCMR register is a 32-bit register that sets the commands issued in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5024h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	CMD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	—	—	—	—	—	—	—	—	OCMD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	OCMD[7:0]	Optional Command	Sets the optional command.	R/W
b15 to b8	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b23 to b16	CMD[7:0]	Command	Sets the command. For details, see the details about the serial flash memory to be used.	R/W
b31 to b24	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.11 SPI Mode Address Setting Register (SMADR)

The SMADR register is a 32-bit register that sets the addresses of the serial flash memory in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5028h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	ADRE[7:0]								ADR[23:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADR[23:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b23 to b0	ADR[23:0]	Address	Sets the address of the serial flash memory.	R/W
b31 to b24	ADRE[7:0]	Address	Sets the value of bits 31 to 24 when the serial flash address is output in 32-bit units. This setting is valid when ADE[3] in SMENR is 1.	R/W

37.2.12 SPI Mode Option Setting Register (SMOPR)

The SMOPR register is a 32-bit register that sets the option data in SPI operating mode.
The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 502Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	OPD3[7:0]								OPD2[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OPD1[7:0]								OPD0[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	OPD0[7:0]	Option Data 0	Sets the option data 0.	R/W
b15 to b8	OPD1[7:0]	Option Data 1	Sets the option data 1.	R/W
b23 to b16	OPD2[7:0]	Option Data 2	Sets the option data 2.	R/W
b31 to b24	OPD3[7:0]	Option Data 3	Sets the option data 3.	R/W

Note: OPD3, OPD2, OPD1, and OPD0 are output in this order.

37.2.13 SPI Mode Enable Setting Register (SMENR)

The SMENR register is a 32-bit register that sets the bit size of the command, optional command, address, option data, and transfer data in SPI operating mode and enables various outputs. Disabling output of all of the command, optional command, address, option data, dummy cycle, and transfer data is prohibited. At least one of them except dummy cycle must be enabled.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

Address(es): A000 5030h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CDB[1:0]		OCDB[1:0]		—	—	ADB[1:0]		—	—	OPDB[1:0]		—	—	SPIDB[1:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	SPIDE[3:0]	Transfer Data Enable	Sets transfer data. The settings below must be used. Otherwise, the operation is not guaranteed. b3 b0 0000: Not transferred 1000: 8 bits transferred (enables data at address 0 of the SPI mode read/write data registers 0) 1100: 16 bits transferred (enables data at addresses 0 and 1 of the SPI mode read/write data registers 0) 1111: 32 bits transferred (enables data at addresses 0 to 3 of the SPI mode read/write data registers 0) Other than above: Setting prohibited	R/W
b7 to b4	OPDE[3:0]	Option Data Enable	Sets the option data to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. b7 b4 0000: Output disabled 1000: OPD3 1100: OPD3, OPD2 1110: OPD3, OPD2, OPD1 1111: OPD3, OPD2, OPD1, OPD0 Other than above: Setting prohibited	R/W
b11 to b8	ADE[3:0]	Address Enable	Sets the address to be output. Use only the settings given below. Otherwise, the operation cannot be guaranteed. b11 b8 0000: Output disabled 0100: ADR[23:16] 0110: ADR[23:8] 0111: ADR[23:0] 1111: ADR[31:0] Other than above: Setting prohibited	R/W
b12	OCDE	Optional Command Enable	Sets the optional command to be output. 0: Optional command output disabled 1: Optional command output enabled	R/W
b13	—	Reserved	This bit is always read as 0. The write value should always be 0.	R/W
b14	CDE	Command Enable	Sets the command to be output. 0: Command output disabled 1: Command output enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b15	DME	Dummy Cycle Enable	Enables insertion of the dummy cycle before the read data. Note 1. Dummy cycle insertion is prohibited for write in SPI operating mode including the case in which a transfer ends with a dummy cycle. Note 2. A setting is prohibited for a transfer starting with a dummy cycle. 0: Dummy cycle insertion disabled 1: Dummy cycle insertion enabled	R/W
b17, b16	SPIDB[1:0]	Transfer Data Bit Size	Sets the transfer data size in bit units. b17 b16 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b19, b18	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b21, b20	OPDB[1:0]	Option Data Bit Size	Sets the option data size in bit units. b21 b20 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b23, b22	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b25, b24	ADB[1:0]	Address Bit Size	Sets the address size in bit units. b25 b24 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b27, b26	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W
b29, b28	OCDB[1:0]	Optional Command Bit Size	Sets the optional command size in bit units. b29 b28 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b31, b30	CDB[1:0]	Command Bit Size	For details, see the details about the serial flash memory to be used. b31 b30 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W

37.2.14 SPI Mode Read Data Register 0 (SMRDR0)

The SMRDR0 register is a 32-bit register that stores the read data in SPI operating mode.
The setting of this register should be read when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.
The alignment of data depends on the access size. For details, see section 37.3.4, Data Alignment.
This register must be accessed in the same unit as the transfer size set in the SPIDE[3:0] bits in the SPI mode enable register (SMENR). It must also be accessed from its own address 0.

Address(es): A000 5038h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	RDATA0[31:0]															
Value after reset:	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x	x

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	RDATA0 [31:0]	Read Data	Holds the data read in SPI operating mode.	R

The contents of this register are modified upon completion of reception in SPI operating mode. Be sure to read data when reception in SPI operating mode is completed.

37.2.15 SPI Mode Write Data Register 0 (SMWDR0)

The SMWDR0 register is a 32-bit register that sets the write data in SPI operating mode.
The setting of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.
The alignment of data depends on the access size. For details, see section 37.3.4, Data Alignment.
This register must be accessed in the same unit as the transfer size set in the SPIDE[3:0] bits in the SPI mode enable register (SMENR). It must also be accessed from its own address 0.

Address(es): A000 5040h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	WDATA0 [31:0]	Write Data	Holds the data to be written in SPI operating mode.	R/W

37.2.16 Common Status Register (CMNSR)

The CMNSR register is a 32-bit register that holds flags indicating the operating state.
The settings of this register are reflected both in external address space read mode and SPI operating mode.

Address(es): A000 5048h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

Bit	Symbol	Bit Name	Description	R/W
b0	TEND	Transfer End Flag	Indicates whether the data transfer has ended. 0: Indicates that data transfer is in progress. 1: Indicates that data transfer has ended.	R
b1	SSLF	SPBSSL Pin Monitor	0: SPBSSL pin is inactive. 1: SPBSSL pin is active.	R
b31 to b2	—	Reserved	These bits are always read as 0.	R

37.2.17 Data Read Dummy Cycle Setting Register (DRDMCR)

The DRDMCR register is a 32-bit register that sets the size and number of dummy cycles to be inserted in external address space read mode.

The settings of this register are enabled when the DME bit in the data read enable setting register (DRENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

b17, b16	DMDB [1:0]	Dummy Cycle Bit Size	Sets the dummy cycle size in bit units. The setting of these bits is combined with the setting of the IO0FV, IO2FV, and IO3FV bits in the common control register (CMNCR) to determine the state of the unused pins during the dummy cycles. The state of the used pins is Hi-Z. b17 b16 0 0: 1 bit 0 1: 2 bits 1 0: 4 bits 1 1: Setting prohibited	R/W
b31 to b18	—	Reserved	These bits are always read as 0. The write value should always be 0.	R/W

37.2.18 SPI Mode Dummy Cycle Setting Register (SMDMCR)

The SMDMCR register is a 32-bit register that sets the size and number of dummy cycles to be inserted in SPI operating mode.

The settings of this register are enabled when the DME bit in the SPI mode enable setting register (SMENR) is 1.

The settings of this register should be changed when the TEND flag in CMNSR is 1; otherwise, the operation cannot be guaranteed.

37.3 Operation

37.3.1 System Configuration

With this module, one serial flash memory can be directly connected (data size of 1, 2, and 4 bits).
Figure 37.2 shows a system configuration example.

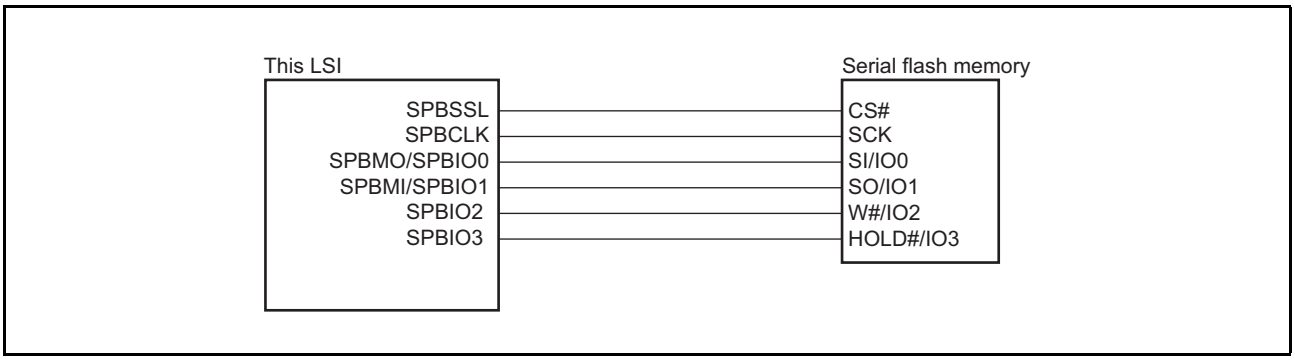

Figure 37.2 System Configuration Example with 4-Bit Data Size of a Serial Flash Memory Connected (BSZ[1:0] Bits in CMNCR = 00)

37.3.2 Address Map

In external address space read mode, the serial flash connected is assigned in the SPI multi I/O bus space. By the DREAR register setting, a maximum of 4 Gbytes can be accessed.

Table 37.4 Address Map

Number of Serial Flash Memories Connected	Internal Address	Max. Access Area
1	1000 0000h to 13FF FFFFh	4 Gbytes
	3000 0000h to 33FF FFFFh (mirror area)	

37.3.3 32-Bit Serial Flash Addresses

Since the SPI multi I/O bus space is 64 Mbytes, only a part of the 32-bit serial flash address area can be directly accessed. Here, the fixed value set in the DREAR register is used as the upper bit value of a 32-bit address.

To output serial flash addresses in 32 bits, set the ADE[3] bit in DRENR to 1, set the range of the external addresses used as the serial flash addresses to the EAC[2:0] bits in DREAR, and set the upper bit value of the 32-bit address as the fixed value to the EAV[7:0] bits in DREAR.

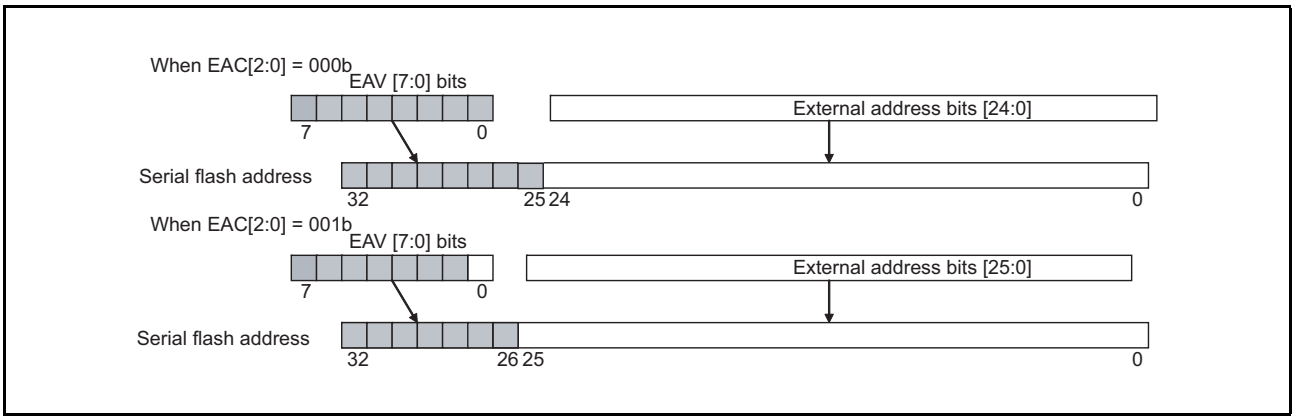

Figure 37.3 32-Bit Address Setting

Setting the ADE[3] bit in DRENR to 1 allows the serial flash address to be output using [31:0] bits.

When EAC[2:0] = 000b, external address bits [24:0] are valid; set the value for [32:25] bits to EAV[7:0].

When EAC[2:0] = 001b, external address bits [25:0] are valid; set the value for [32:26] bits to EAV[7:1].

When one serial flash memory is connected, address bits [31:0] are used.

37.3.4 Data Alignment

Data alignment can be set by using the SFDE bit in the common control register (CMNCR). Data alignment in data read mode and in SPI mode are shown in Figure 37.4 and Figure 37.5, respectively.

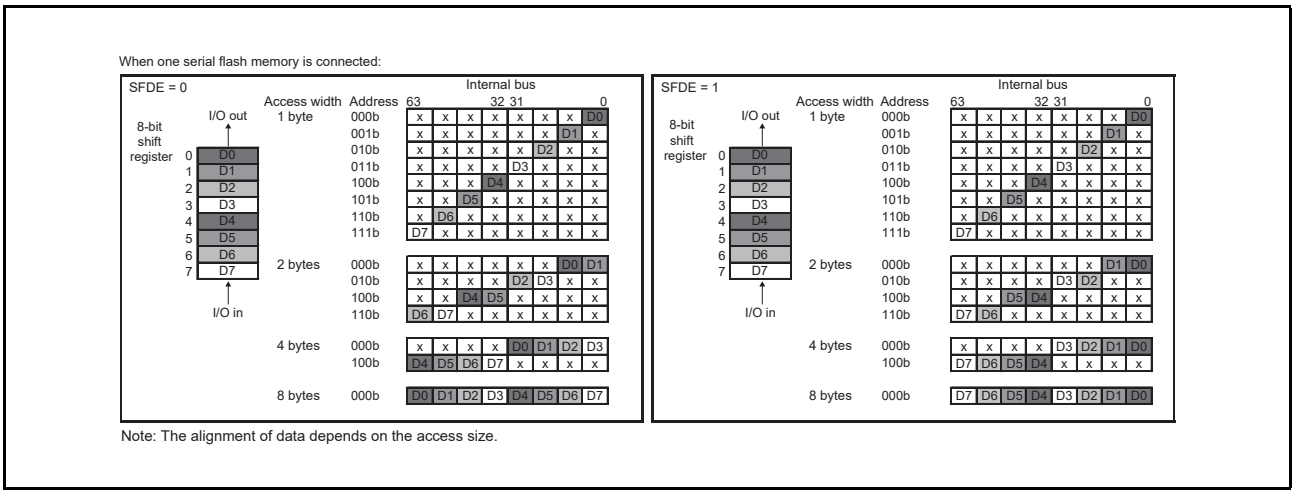

Figure 37.4 Data Alignment in External Address Space Read Mode

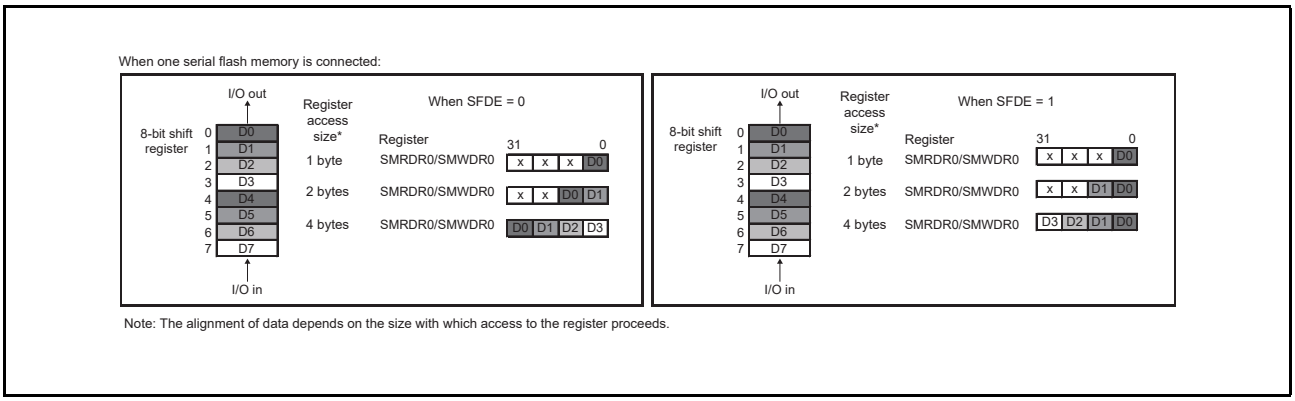

Figure 37.5 Data Alignment in SPI Operating Mode

37.3.5 Operating Modes

This module has two operating modes: external address space read mode and SPI operating mode.
In external address space read mode, a read access to the SPI multi I/O bus space is converted into SPI communication and data is received. After data acquisition, data is returned to the bus master that is the issuing source. For details, see section 37.3.6, External Address Space Read Mode.
In SPI operating mode, arbitrary SPI communication is carried out based on the register settings. For details, see section 37.3.8, SPI Operating Mode.

37.3.6 External Address Space Read Mode

A read access to the SPI multi I/O bus space can be converted into SPI communication in external address space read mode. Further, the commands, optional commands, option data, and dummy cycle issued for reading can be modified by the register settings.
In external address space read mode, either normal read operation or burst read operation can be selected. The transfer format is determined by the settings of the common control register (CMNCR), SSL delay register (SSLDR), bit rate setting register (SPBCR), data read control register (DRCR), data read command setting register (DRCMR), data read extended address setting register (DREAR), data read option setting register (DROPR), data read enable setting register (DRENR), and data read dummy cycle setting register (DRDMCR).

(1) Normal Read Operation

When the RBE bit in DRCR is set to 0, normal read operation is performed.
In the normal read operation, the data of 8 bits, 16 bits, and 32 bits are read for respectively a byte, a word, and a longword read access. After reading, the SPBSSL signal is inactivated.
The normal read operation timing is shown in Figure 37.6.
t1 is the time period from the time the SPBSSL signal is activated to the time the clock is output from the SPBCLK signal (clock delay). t2 is the time period from transmission of the last edge of the SPBCLK signal of a transfer to the time the SPBSSL signal is inactivated (SPBSSL negation delay). t3 is the time period from one transfer end to the next transfer start (next access). For details of t1, t2, and t3, see section 37.3.9, Transfer Format.

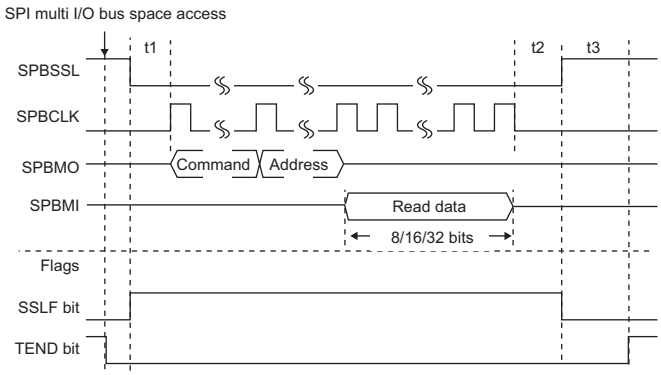

Figure 37.6 Normal Read Operation Timing

(2) Burst Read Operation

When the RBE bit in DRCR is set to 1, burst read operation is performed. Read cache is enabled in the burst read operation. For read cache operation, see section 37.3.7, Read Cache.

For reading bytes, words, or longwords, the read cache is first referred to for the data. When the read cache contains the data, the data is read from the read cache without accessing the serial flash memory. When the read cache does not contain the data, burst read operation is performed in the serial flash memory and the read data is stored in the read cache. The data transfer length at that time is 64 bits × RBURST[3:0] bits and the data is always read from the 64-bit boundary.

The status of the SPBSSL signal after data transfer can be selected by using the SSLE bit in DRCR. When the SSLE bit is set to 0, the SPBSSL signal is always inactivated after data transfer. For an operation performed when the SSLE bit is set to 1, see section 37.3.6, (3) Burst Read Operation with Automatic SPBSSL Inactivation, just below.

A pattern diagram of this operation and a burst read operation timing diagram when SSLE bit is set to 0 are shown in Figure 37.7 and Figure 37.8.

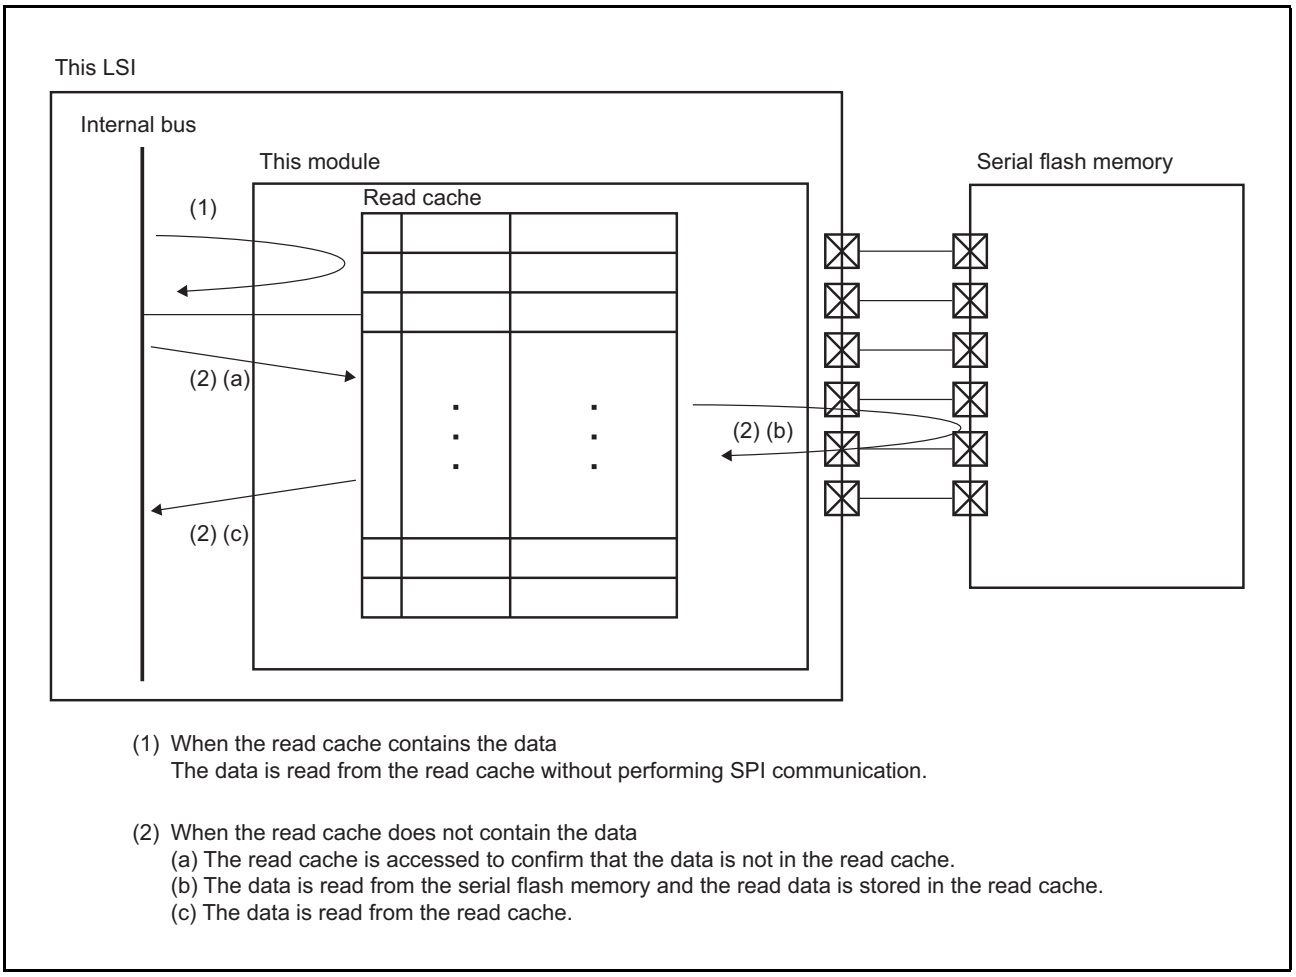

Figure 37.7 Burst Read Operation

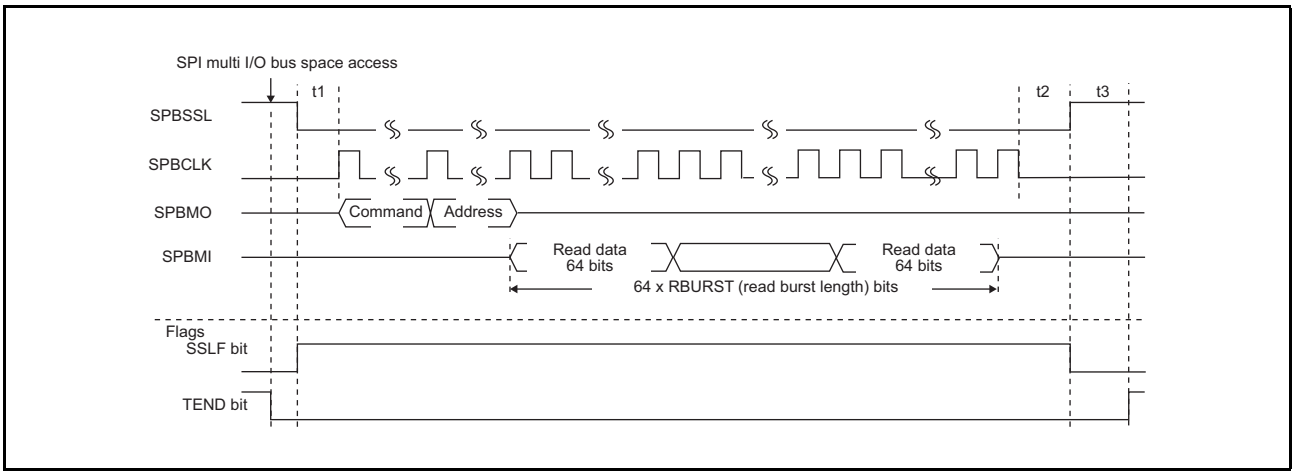

Figure 37.8 Burst Read Operation Timing (SSLE Bit = 0)

(3) Burst Read Operation with Automatic SPBSSL Inactivation

When SSLE bit in DRCR is set to 1, this module does not inactivate the SPBSSL signal after the burst read transfer. When accessing the next time, if the address is continuous with the previous read address, the burst read operation is performed without issuing the command, optional command, address, option data, or dummy cycle. If the address is not continuous with the previous read address, the SPBSSL signal is once inactivated and the burst read operation is performed after issuing the command, optional command, address, option data, or dummy cycle.
Burst read timing diagrams for continuous address and non-continuous address are shown in Figure 37.9 and Figure 37.10.

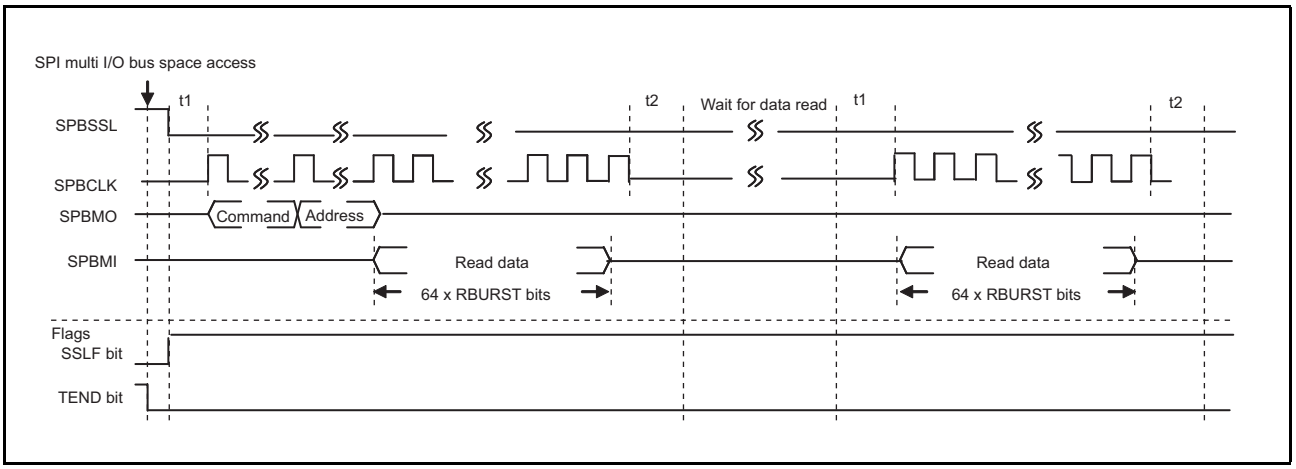

Figure 37.9 Burst Read Timing for Continuous Address (SSLE Bit = 1)

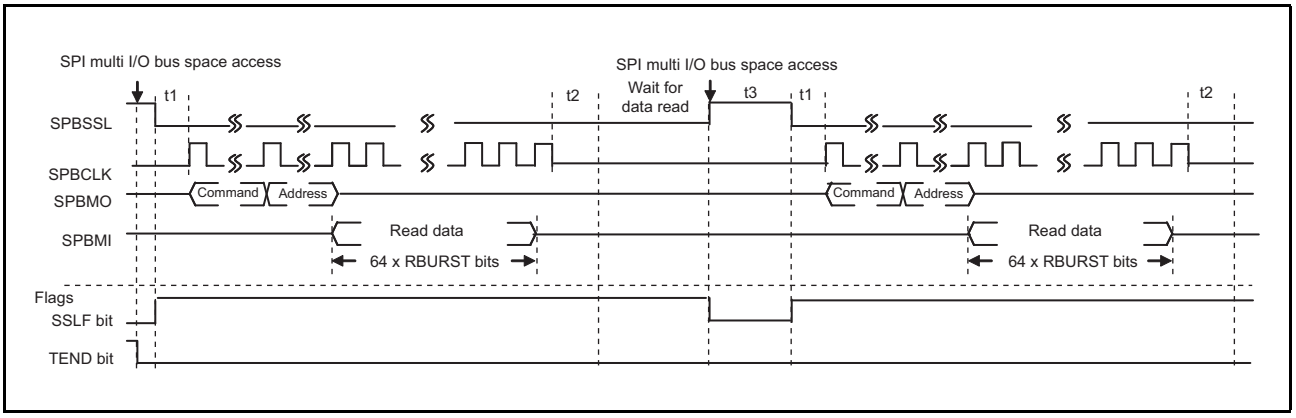

Figure 37.10 Burst Read Timing for Non-Continuous Address (SSLE Bit = 1)

For the next access after inactivation of the SPBSSL signal with the SSLN bit in DRCR with this operation, read SSLF = 0 in CMNSR to confirm that the SPBSSL signal has been inactivated.

(4) Initial Setting Flow

An example of an initial setting flow in external address space read mode is shown in Figure 37.11.

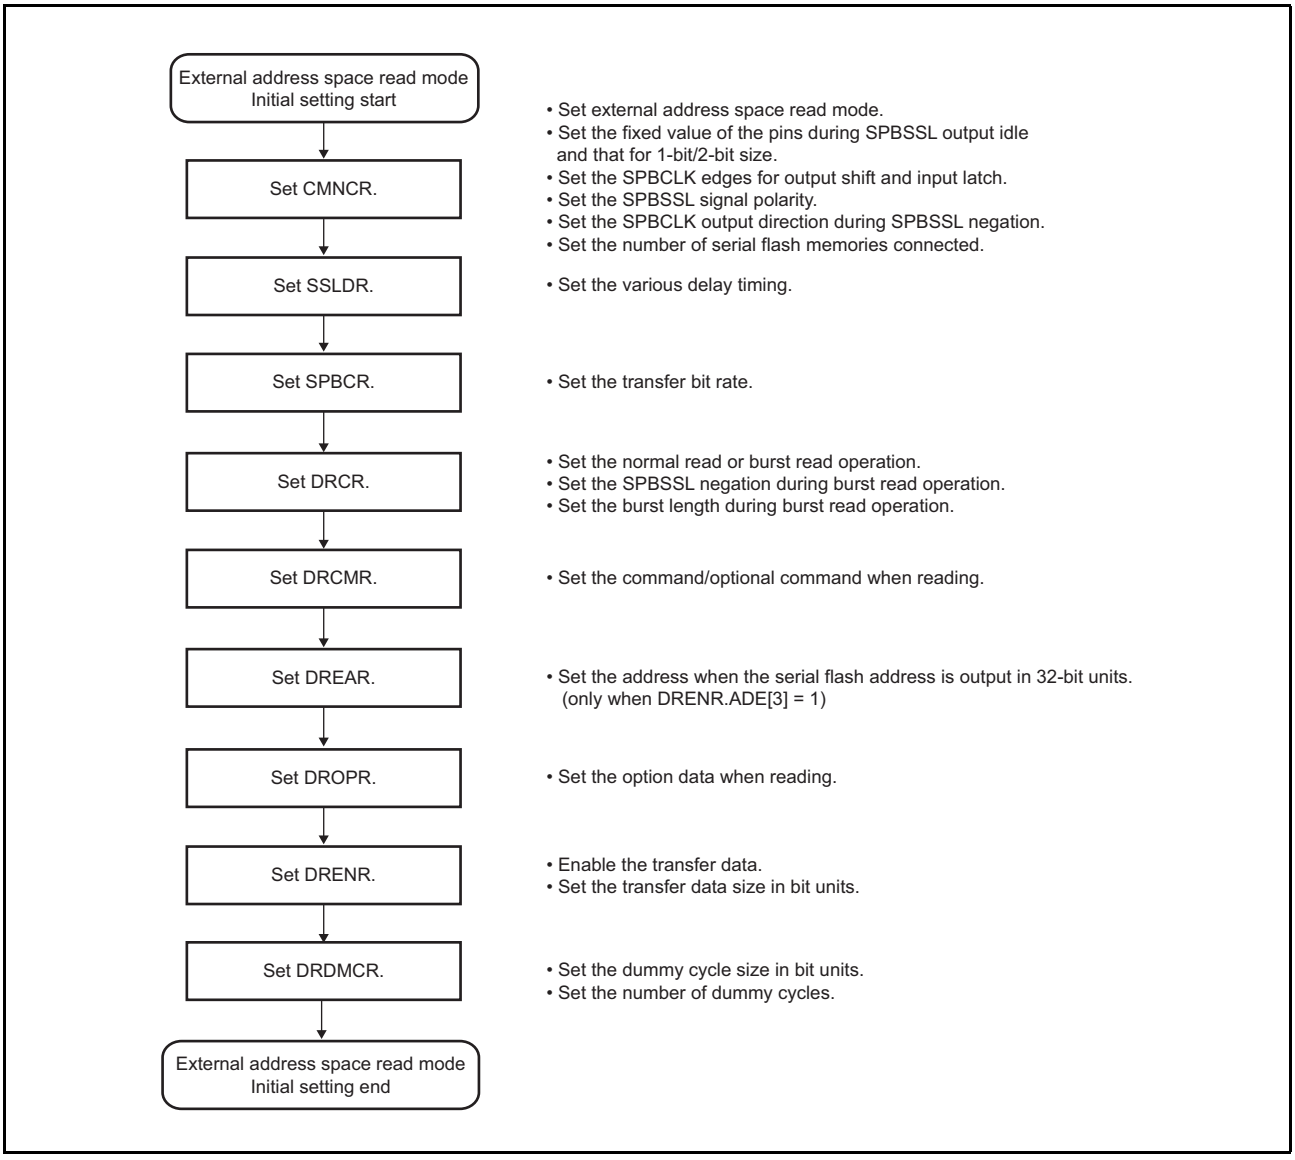

Figure 37.11 Example of Initial Setting Flow in External Address Space Read Mode

37.3.7 Read Cache

This module has a simple built-in read cache. The read cache can be used during external address space read mode and burst read operation. The read cache is configured with a line size of 64 bits and 16 entries.
Read cache configuration is shown in Figure 37.12.

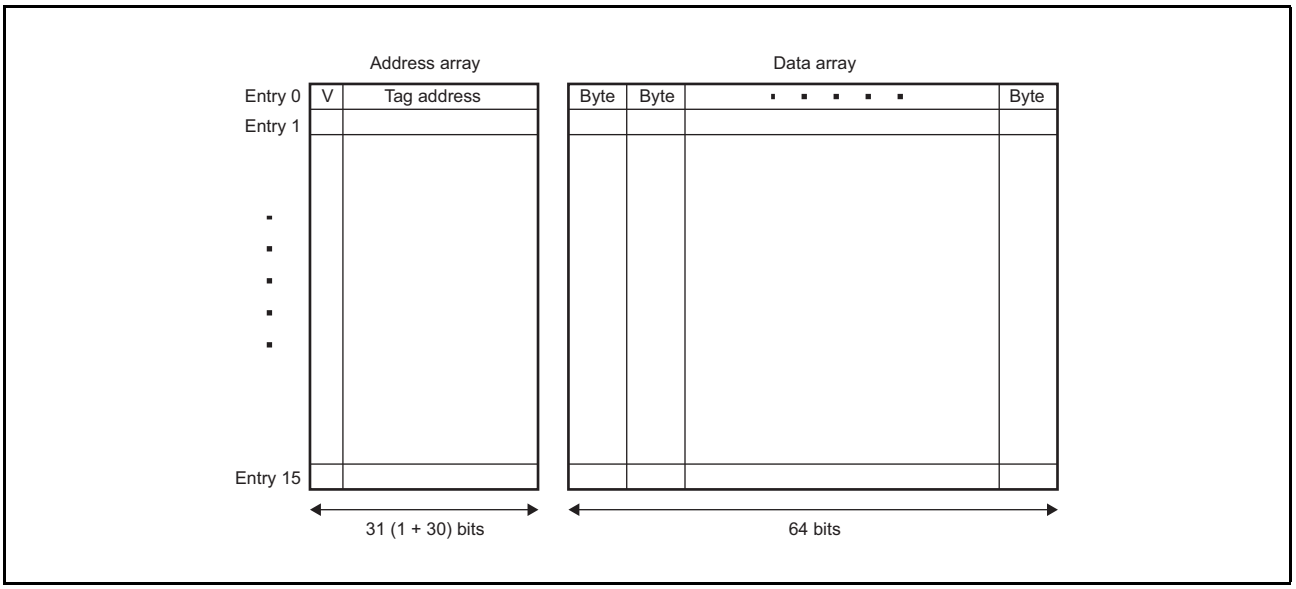

Figure 37.12 Read Cache Configuration

(1) Address Array

The V bit in Figure 37.12 indicates whether the entry data is valid. When the V bit is 1, the data is valid and when V bit is 0, the data is invalid.
The tag address bits hold the address used by the serial flash memory. An address is composed of bits 32 to 3. Address bits 23 to 3 are enabled when address output is 24 bits.
Address bits 31 to 3 are enabled when address output is 32 bits.

(2) Data Array

It retains the 64-bit read data. Registration in the read cache is performed in line units.

(3) Read Operation

If read data is hit in the cache, data is read from the read cache. In case of miss-hit, after the 64 × RBURST (read burst length) data is read from the serial flash memory and the read cache is updated, the data is returned to the bus master.

(4) Data Replacement

Data update is managed by the write pointer. In case of miss-hit of read data, the RBURST (read burst length) portion data is replaced starting at the entry specified by the write pointer. In other words, the data is replaced in the storage order of the data. Whether data is referred to or not will not affect the replacement order of data.

37.3.8 SPI Operating Mode

This module can carry out an arbitrary SPI operation by using the register settings.
The transfer format is determined by the settings of the common control register (CMNCR), SSL delay register (SSLDR), bit rate setting register (SPBCR), SPI mode control register (SMCR), SPI mode command setting register (SMCMR), SPI mode address setting register (SMADR), SPI mode option setting register (SMOPR), and SPI mode enable setting register (SMENR), SPI mode read data register (SMRDR), SPI mode write data register (SMWDR), and SPI mode dummy cycle setting register (SMDMCR).
SPI operating mode can be used for reading the status of the serial flash memory and writing to the serial flash memory. In this mode, one transfer refers to the operation from when the SPIE bit in SMCR is set to 1 to when the TEND bit is set to 1.

(1) Transfer Start

The transfer of data is started in the set transfer format by setting the SPIE bit in SMCR to 1. When write operation is enabled, the SPI mode write data register is transmitted to the serial flash memory. When read operation is enabled, data read from the serial flash memory is stored into the SPI mode read data register.
The SPI operation timing is shown in Figure 37.13.

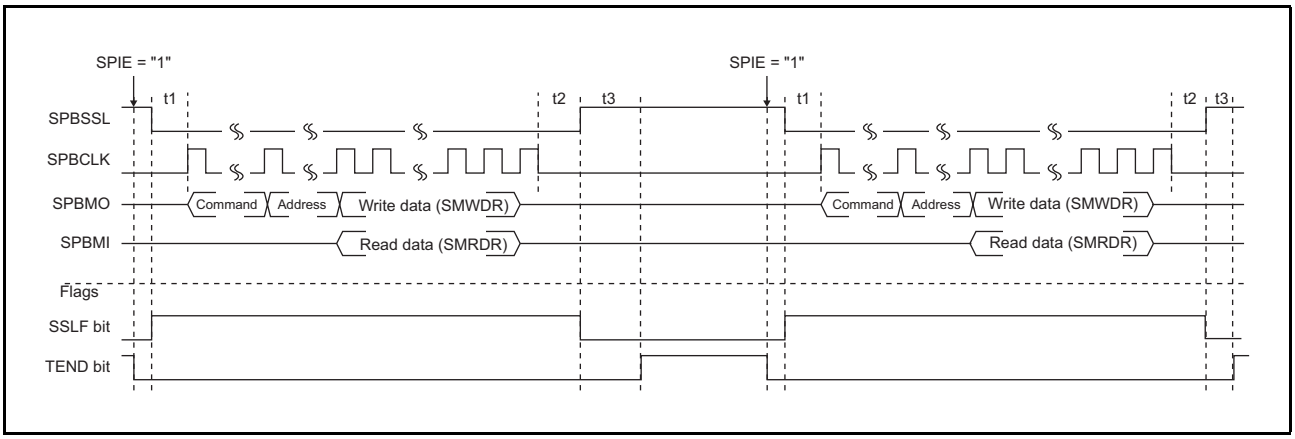

Figure 37.13 SPI Operation Timing

(2) Read/Write Enable

- Read operation: Data can be read by setting the SPIRE bit in SMCR to 1. The read data is stored into SMRDR.
- Write operation: Data can be written by setting the SPIWE bit in SMCR to 1. The data stored in SMWDR is output.

When the data size is set to 1 bit using the SPIDB[1:0] bits in SMENR, data can be transmitted and received by setting the SPIRE and SPIWE bits to 1. However, when the data size is set to 2 or 4 bits by using the SPIDB[1:0] bits, only one of the SPIRE and SPIWE bits should be enabled. The operation is not guaranteed if both the bits are enabled.

(3) Retention of SPBSSL Pin Activation

By setting the SSLKP bit in SMCR to 1, activation of the SPBSSL signal can be continued till the next transfer. With this function, the transfer can be carried out continuously with the SPBSSL signal kept in the active state.
The data transfer timing using the SSLKP bit is shown in Figure 37.14.

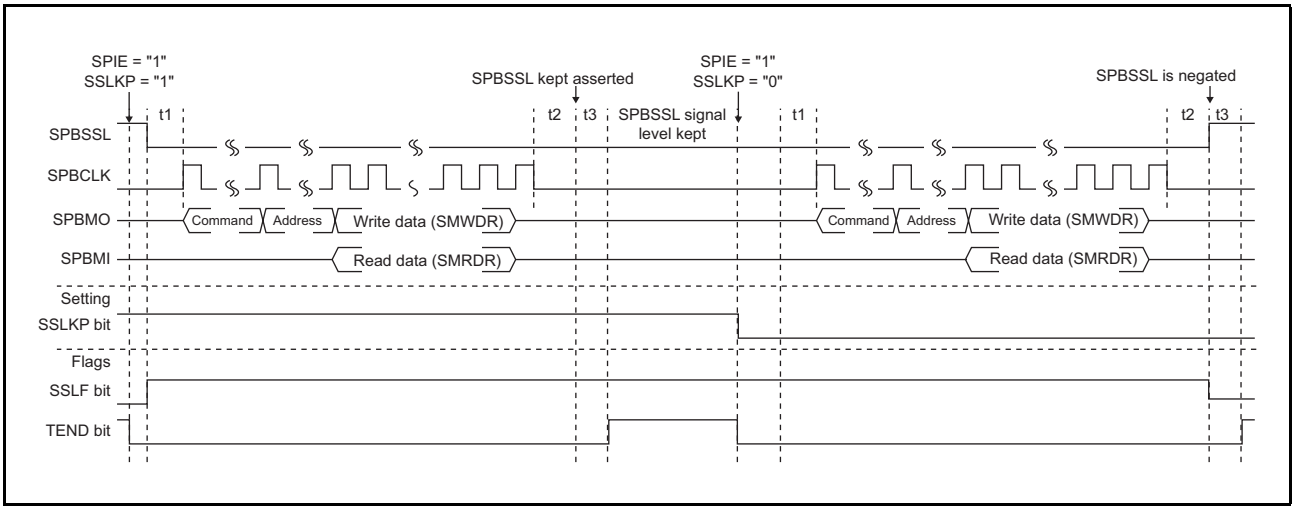

Figure 37.14 Data Transfer Timing using the SSLKP Bit

(4) Initial Setting Flow

An example of an initial setting flow in SPI operating mode is shown in Figure 37.15.

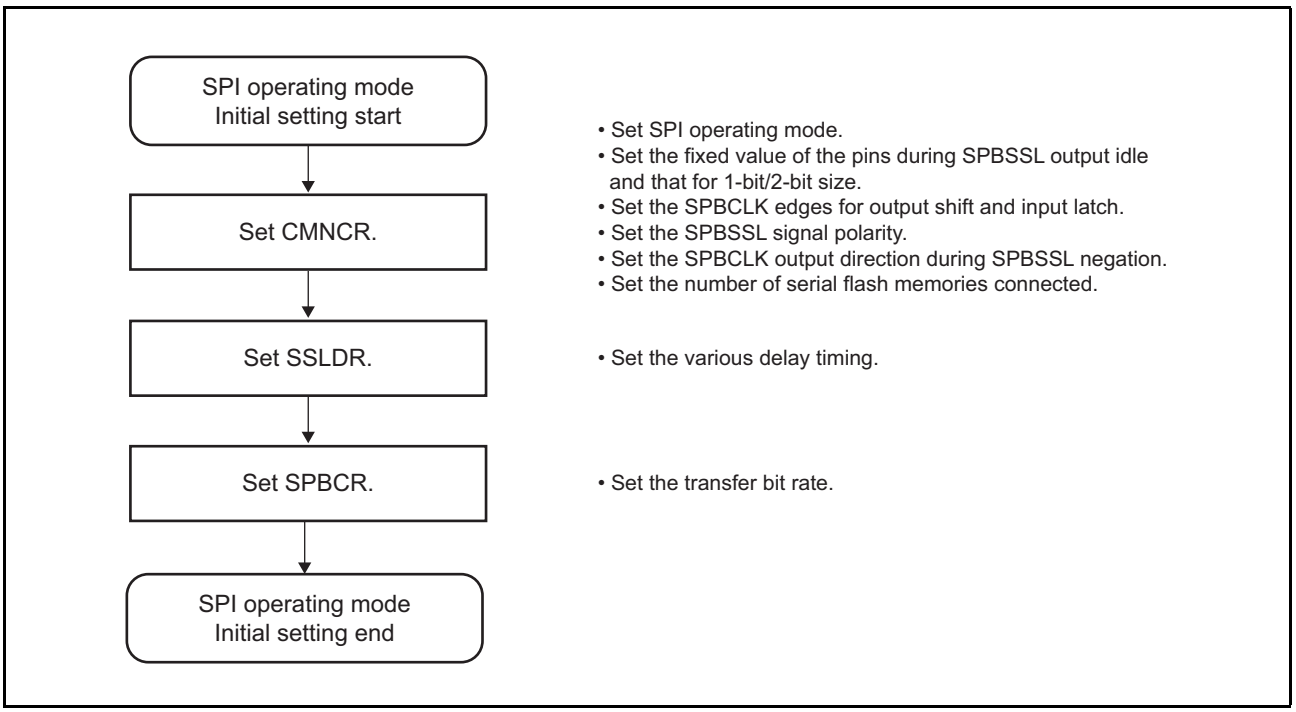

Figure 37.15 Example of Initial Setting Flow in SPI Operating Mode

(5) Data Transfer Setting Flow

An example of a data transfer setting flow in SPI operating mode is shown in Figure 37.16.

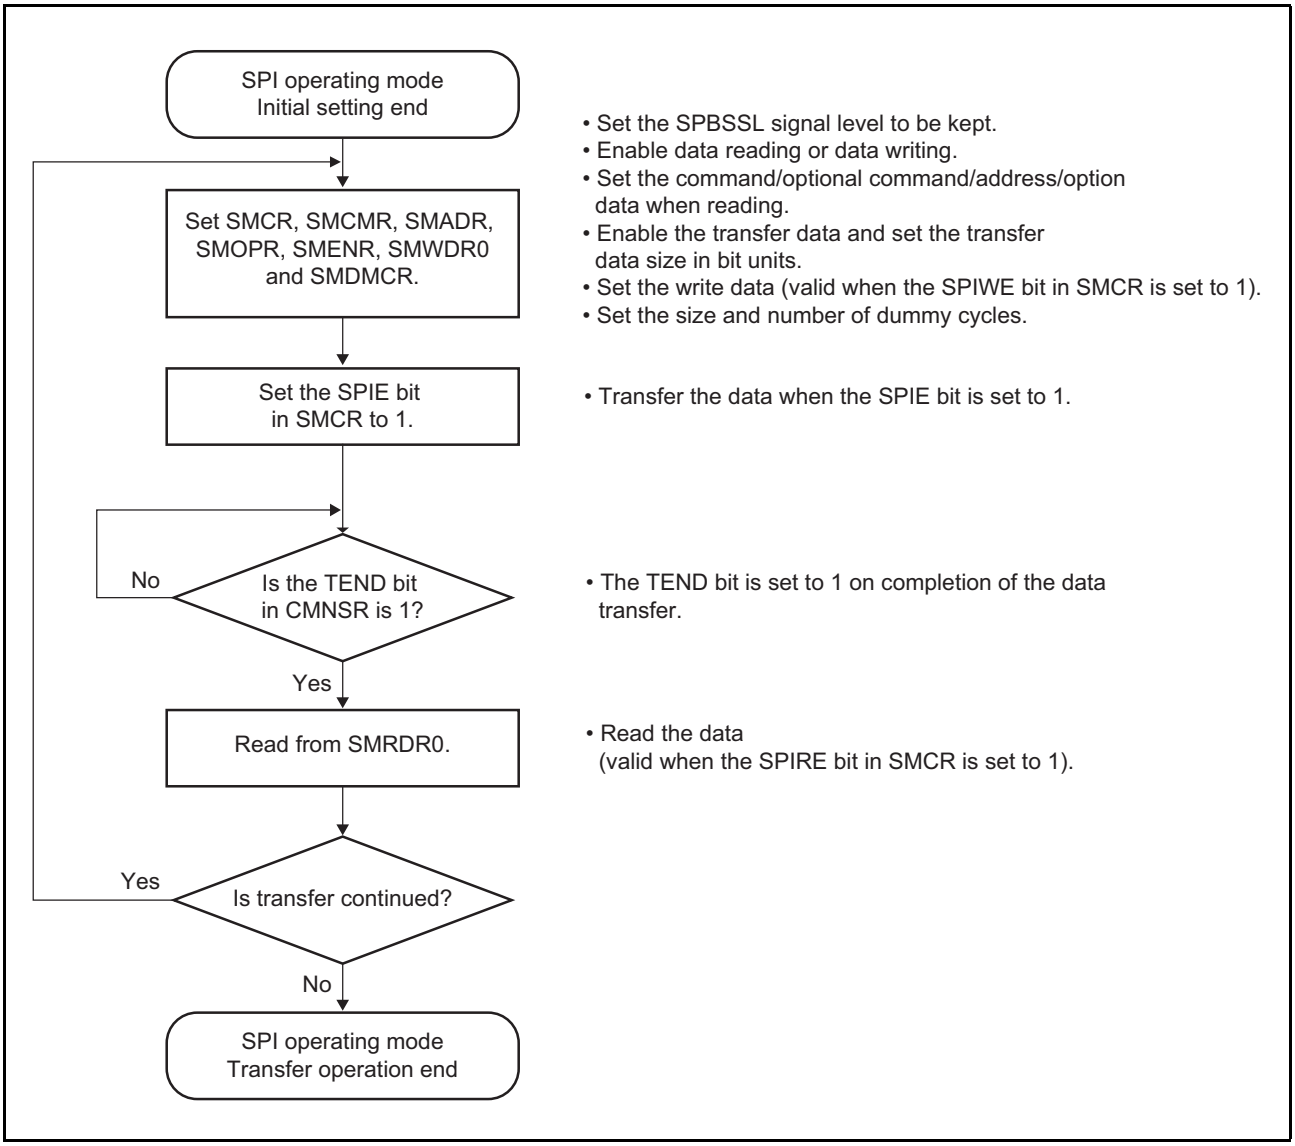

Figure 37.16 Example of a Data Transfer Setting Flow in SPI Operating Mode

37.3.9 Transfer Format

(1) SPBSSL Pin Enable Polarity Control

The enable polarity of the SPBSSL signal can be changed with the SSLP bit in CMNCR.

(2) SPBCLK Output

The output level of the SPBCLK signal while the SPBSSL signal is inactive can be set with the CPOL bit in CMNCR.

(3) Data Transmission and Reception Timing

Data is transmitted and received at either the odd or even edges. The data transmission timing can be set to the odd or even edge with the CPHAT bit in CMNCR. Similarly, the data reception timing can be set to the odd or even edge with the CPHAR bit in CMNCR.

(4) Delay Settings

t1 is the time period from the time the SPBSSL signal is activated to the clock output of the SPBCLK signal (clock delay). It can be set with the SCKDL[2:0] bits in SSLDR. t2 is the time period from the time the clock output of the SPBCLK signal is stopped to the time the SPBSSL signal is inactivated (SPBSSL negation delay). It can be set with the SLNDL[2:0] bits in SSLDR. t3 is the time period required to prevent SPBSSL signal activation for the next transfer after the end of the previous transfer (next access delay). It can be set with the SPNDL[2:0] bits in SSLDR.

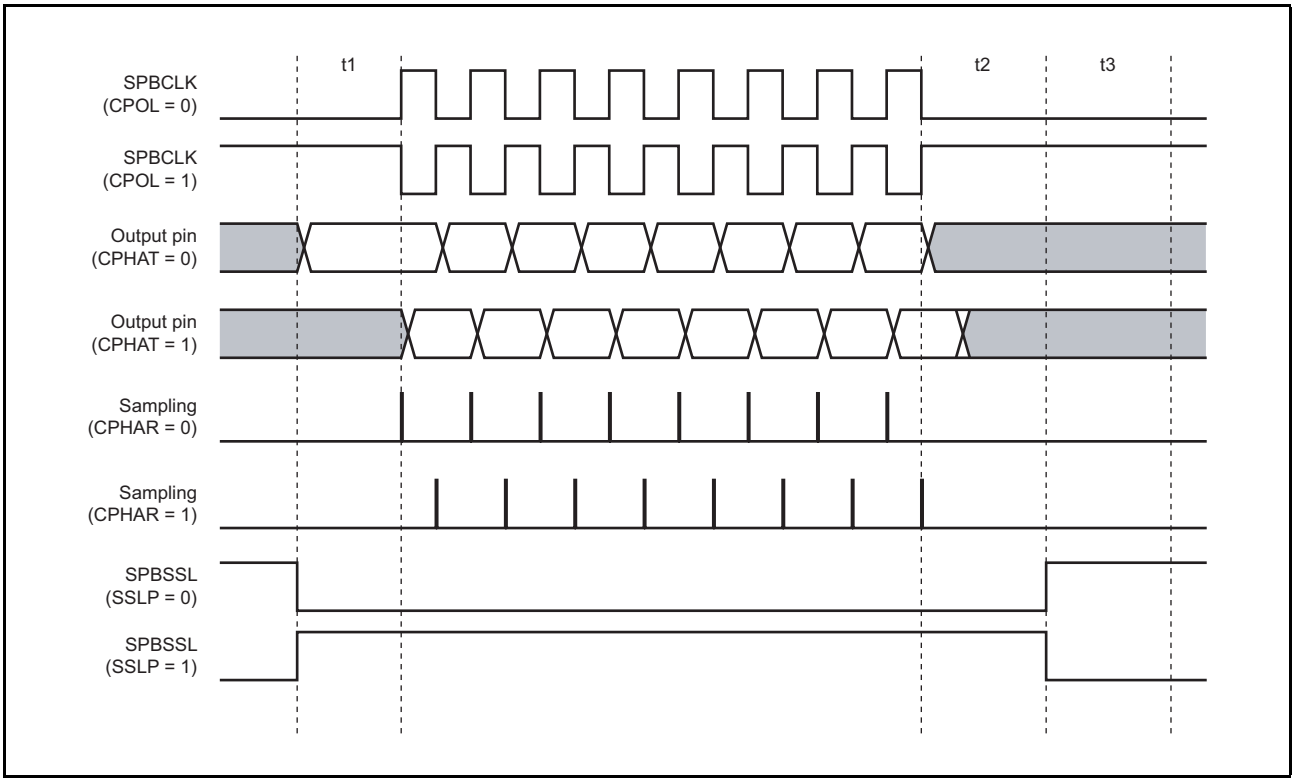

Figure 37.17 SDR Transfer Format

37.3.10 Data Format

This module can input and output data in the order of command, optional command, address, option data, dummy cycle, and data.

(1) Data Registers

Table 37.5 shows the input and output data.

Table 37.5 Data Registers

Data	External Address Space Read Mode	SPI Operating Mode
Command (8 bits)	CMD[7:0] bits in DRCMR	CMD[7:0] bits in SMCMR
Optional command (8 bits)	OCMD[7:0] bits in DRCMR	OCMD[7:0] bits in SMCMR
Address (32/24 bits)	32 bits: DREAR.EAV[6:1 to 0] bits + lower [25 to 24:0] bits of the read address. 24 bits: Lower [23:0] bits of the read address	32 bits: ADR[31:0] bits in SMADR 24 bits: ADR[23:0] bits in SMADR
Option data (8 bits × 4)	DROPR	SMOPR
Dummy cycle (1 to 8 cycles)	DRDMCR	SMDMCR (only when read)
Transfer data	Normal read: 8/16/32 bits Burst read: 64 × RBURST bits	Read: SMRDR0, SMRDR1 Write: SMWDR0, SMWDR1

(2) Data Enable

In external address space read mode, transfer enable of the command, optional command, address, option data, and dummy cycle can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], and DME bits in DRENR, respectively. The size and number of dummy cycles can be controlled with the data read dummy cycle setting register (DRDMCR). Similarly, in SPI operating mode, enable of the command, optional command, address, option data, dummy cycle, and transfer data can be controlled with the CDE, OCDE, ADE[3:0], OPDE[3:0], DME, and SPIDE[3:0] bits in SMENR, respectively. However, disabling all the above parameters is prohibited in SPI operating mode. At least one of them except dummy cycle must be enabled. The size and number of dummy cycles can be controlled with the SPI mode dummy cycle setting register (SMDMCR).

For the address and option data in external address space read mode; and the address, option data, and transfer data in SPI operating mode, the enable bit setting allowed is determined according to the transfer data size. For the allowed setting combinations of the enable bits and transfer data size, refer to the description of the pertinent register.

If these enable bits are disabled, the data is not output, and input and output of the next data is carried out. The command, optional command, address, and option data are always output. During dummy cycles, the state of the used pins is Hi-Z. In external address space read mode, data is always input; and in SPI operating mode, input and output of data is determined based on the settings of the SPIRE and SPIWE bits in SMCR.

There are some restrictions on dummy cycle insertion; refer to the description of the DME bits in DRENR and SMENR for details.

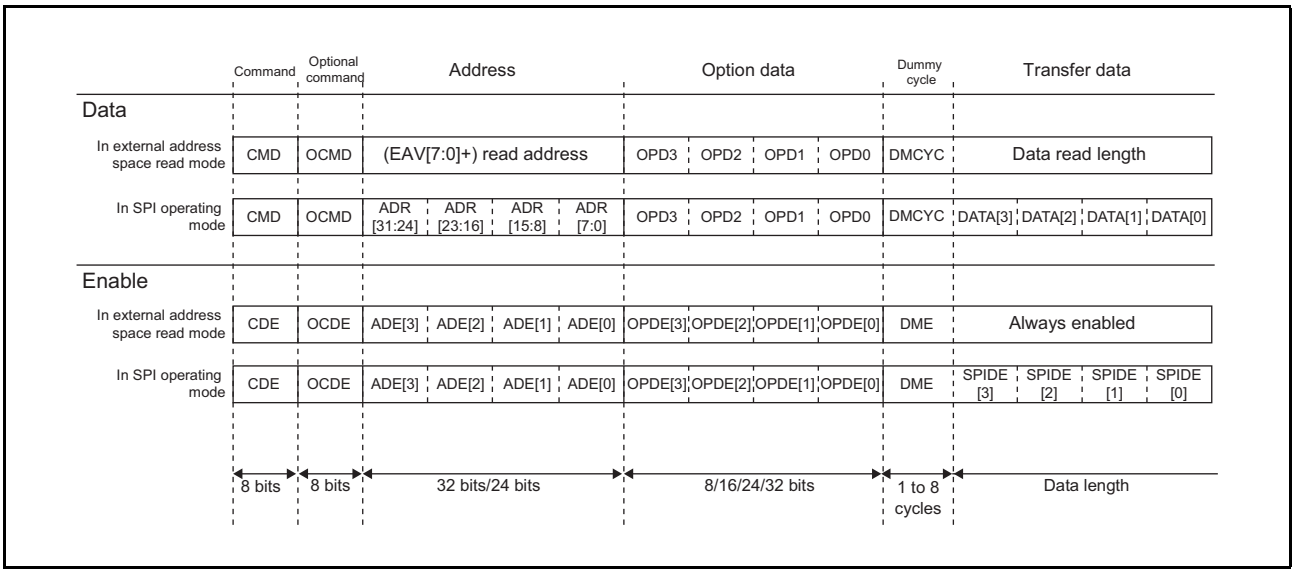

Figure 37.18 Data and Enable

(3) Bit Size

In external address space read mode, the size of the command, optional command, address, option data, and the read data in bit units is respectively controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and DRDB[1:0] bits in DRENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in DRDMCR.
Similarly, in SPI operating mode, the size of the command, optional command, address, option data, and read write data in bit units is controlled with the CDB[1:0], OCDB[1:0], ADB[1:0], OPDB[1:0], and SPIDB[1:0] bits in SMENR. The size of the dummy cycle in bit units is also controlled with the DMDB[1:0] bits in SMDMCR.

(a) 1-bit size

When the size is set to 1 bit, SPBMI pin will be the input pins and SPBMO pin will be the output pins. SPBIO2, and SPBIO3 pins are not used.
Figure 37.19 show the transfer format example.

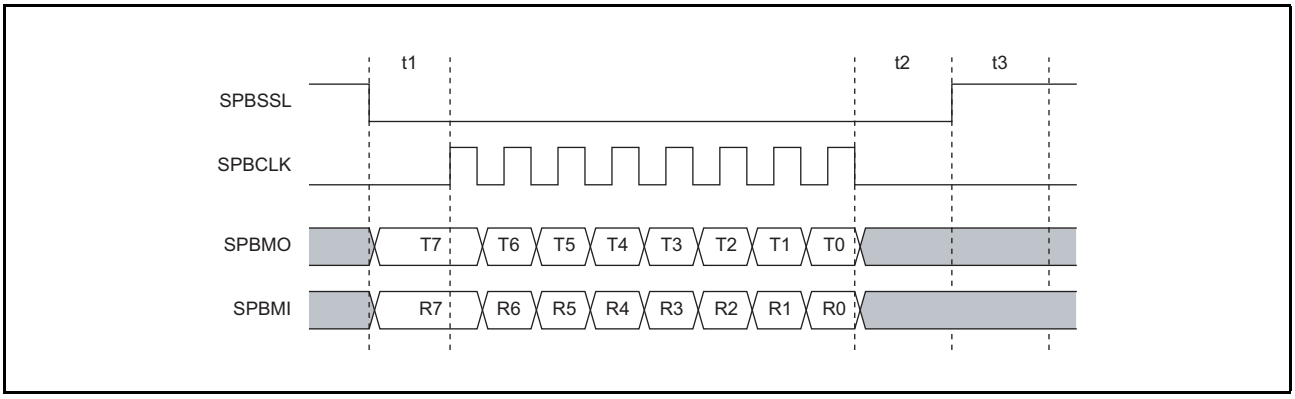

Figure 37.19 Transfer Format Example with 1-Bit Data Size and One Serial Flash Memory Connected

(b) 2-bit size

When the size is set to 2 bits, SPBIO0 and SPBIO1 pins will be either the input pins or the output pins. SPBIO2, and SPBIO3 pins are not used.
Figure 37.20 show the transfer format example.

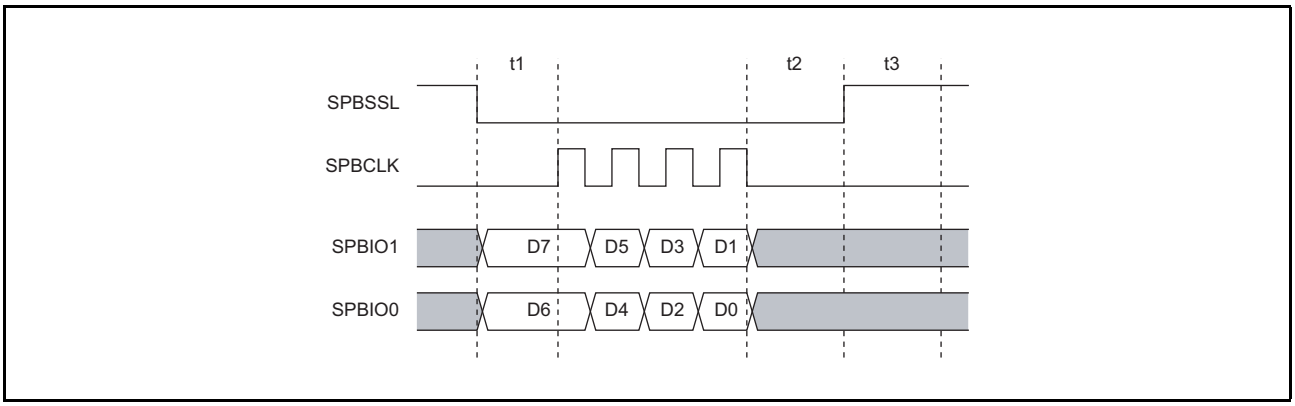

Figure 37.20 Transfer Format Example with 2-Bit Data Size and One Serial Flash Memory Connected

(c) 4-bit size

When the size is set to 4 bits, SPBIO0, SPBIO1, SPBIO2, and SPBIO3 pins will be either the input pins or the output pins.

Figure 37.21 show the transfer format examples.

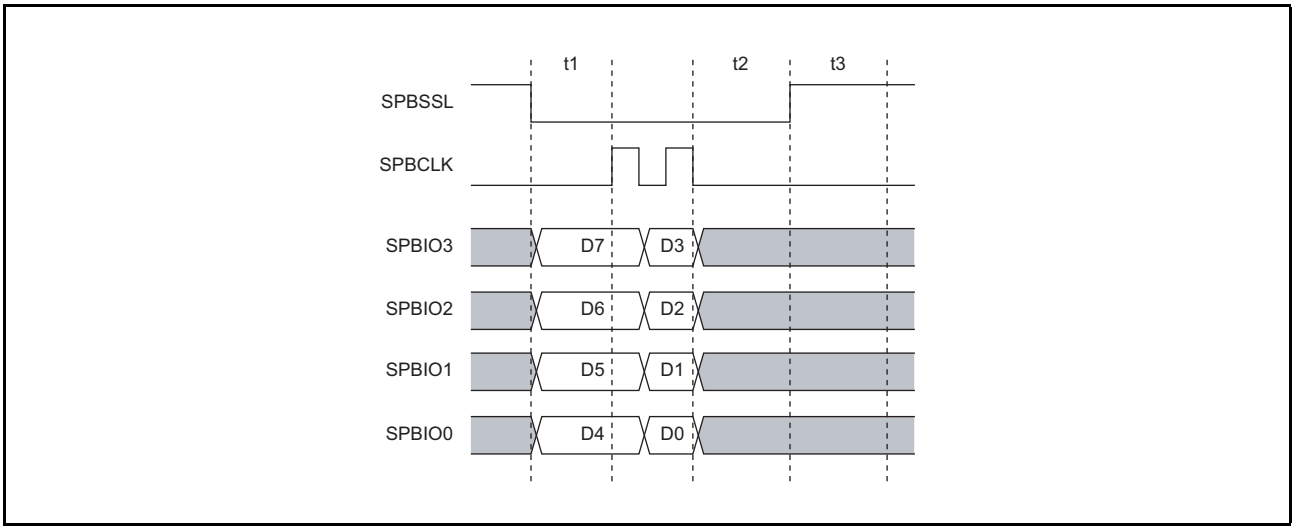

Figure 37.21 Transfer Format Example with 4-Bit Data Size and One Serial Flash Memory Connected

37.3.11 Data Pin Control

With this module, the status of pins can be automatically changed based on the data size to be used and the read/write settings. The inactivation status of the SPBSSL signal can be set with the MOIIO3, MOIIO2, MOIIO1, and MOIIO0 bits in CMNCR. The SPBSSL and SPBCLK pins are always output pins. The status of respective pins is specified in Table 37.6 to Table 37.9.

Table 37.6 Pin Status (1)

		SPBSSL Activation		
		Command, Optional Command, Address, Option Data		
Pin	**SPBSSL Inactivation**	**1-Bit Size**	**2-Bit Size**	**4-Bit Size**
SPBMO/SPBIO0	MOIIO0 bit value	Output	Output	Output
SPBMI/SPBIO1	MOIIO1 bit value	Hi-Z	Output	Output
SPBIO2	MOIIO2 bit value	IO2FV bit value	IO2FV bit value	Output
SPBIO3	MOIIO3 bit value	IO3FV bit value	IO3FV bit value	Output

Table 37.7 Pin Status (2)

	Transfer Data					
	External Address Space Read Mode			SPI Operating Mode		
				SPIRE Bit = 1, SPIWE Bit = 0		
Pin	**1-Bit Size**	**2-Bit Size**	**4-Bit Size**	**1-Bit Size**	**2-Bit Size**	**4-Bit Size**

SPBIO2	IO2FV bit value	IO2FV bit value	Hi-Z
SPBIO3	IO3FV bit value	IO3FV bit value	Hi-Z

37.3.12 SPBSSL Pin Control

Inactivation conditions of the SPBSSL signal are as follows.

(1) External Address Space Read Mode

(a) Normal read operation (RBE bit in DRCR = 0)

SPBSSL inactivated after the data transfer and t2 cycle are completed.

(b) Burst read without automatic SPBSSL inactivation (RBE bit in DRCR = 1, SSLE bit in DRCR = 0)

SPBSSL inactivated after the data transfer and t2 cycle are completed.

(c) Burst read with automatic SPBSSL inactivation (RBE bit in DRCR = 1, SSLE bit in DRCR = 1)

- SPBSSL inactivated after t2 cycle when the read address is not continuous with the previously read address
- SPBSSL inactivated after the SSLN bit in DRCR is set to 1

(2) SPI Operating Mode

(a) SPBSSL pin activation not retained (SSLKP bit in SMCR = 0)

SPBSSL inactivated after the data transfer and t2 cycle are completed.

(b) SPBSSL pin activation retained (SSLKP bit in SMCR = 1)

SPBSSL not inactivated.
When to be inactivated, data should be transferred after setting the SSLKP bit to 0.

37.3.13 Flags

This module has two flag bits SSLF and TEND in CMNSR. These bits are read-only bits.

(1) SSLF Bit

This bit indicates the SPBSSL pin status. The status is 1 when the SPBSSL signal is active, and the status is 0 when the SPBSSL signal is inactive.

(2) TEND Bit

This bit indicates whether transfer of data is in progress or the transfer of data has ended.
During t1 time period, data transfer, t2 time period, t3 time period, and waiting for read access by burst read and SPBSSL automatic inactivation, the TEND bit is read as 0 to indicate that the transfer of data is in progress.
When other than the above, the TEND bit is read as 1 to indicate that transfer of data has ended.

(3) Register Re-writing Timing

The status of the TEND bit determines the rewritable registers.
The registers which can be written to, except the SSLN bit in DRCR, should be modified when TEND = 1.
Read SMRDR0 when TEND = 1.
CMNSR can always be read.

37.4 Usage Notes

37.4.1 Notes on Transfer to Read Data in SPI Operating Mode

If the setting for the bit mode is for division by two or more in SPI operating mode, take note of the following points for caution when setting the SPI mode enable setting register (SMENR) to enable transfer only for reading data.
“Transfer only for reading data” indicates transfer to read data while the CDE, OCDE, ADE[3:0], and OPDE[3:0] bits in SMENR are all 0.

(1) Transfer to read data while the signal on the SPBSSL pin is inactivated

Set the SMENR.SPIDE[3:0] bits to 1100b or 1111b when transfer only for reading data is to proceed.
Transfer will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000b.

(2) Transfer to read data while the signal on the SPBSSL pin is activated

When transfer only for reading data is to proceed, set the SMENR.SPIDE[3:0] bits to 1100b or 1111b, or end the immediately preceding transfer with reading data.
When the immediately preceding transfer is of a command, optional command, address, or option data, or is transfer for writing data, the subsequent transfer only for reading data will not proceed normally if the setting of the SMENR.SPIDE[3:0] bits is 1000b.

37.4.2 Notes on Starting Transfer from the SPBSSL Signal Retained State in SPI Operating Mode

Be sure to set the SPIWE bit in the SMCR register to 1 when the transfer of a command, optional command, address, or option data is started while the SPBSSL signal is active in SPI operating mode.

37.4.3 Note on Initialization

When using this module, do not set both SPBR[7:0] = 00h and BRDV[1:0] = 00b in the bit rate setting register (SPBCR).

38. CRC Operation Units (CRC)

Cyclic redundancy check (CRC) operation units generate CRC codes.

38.1 Overview

Table 38.1 describes the CRC operation unit specifications. Figure 38.1 shows a block diagram of a CRC operation unit.

Table 38.1 CRC Operation Unit (CRC) Specifications

Item	Specifications
Data subject to CRC operation	A CRC code can be generated for any data that is 8, 16, or 32 bits long.
CRC generation polynomial expression	One of the following polynomials can be selected: • 32-bit Ethernet CRC (32-Ethernet) $X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$ • 16-bit CCITT CRC (16-CCITT) $X^{16} + X^{12} + X^5 + 1$ • 8-bit SAE J1850 CRC (8-SAE J1850) $X^8 + X^4 + X^3 + X^2 + 1$ • 8-bit 0x2F CRC (8-0x2F) $X^8 + X^5 + X^3 + X^2 + X + 1$
Low-power consumption function	Module-stop state can be set.

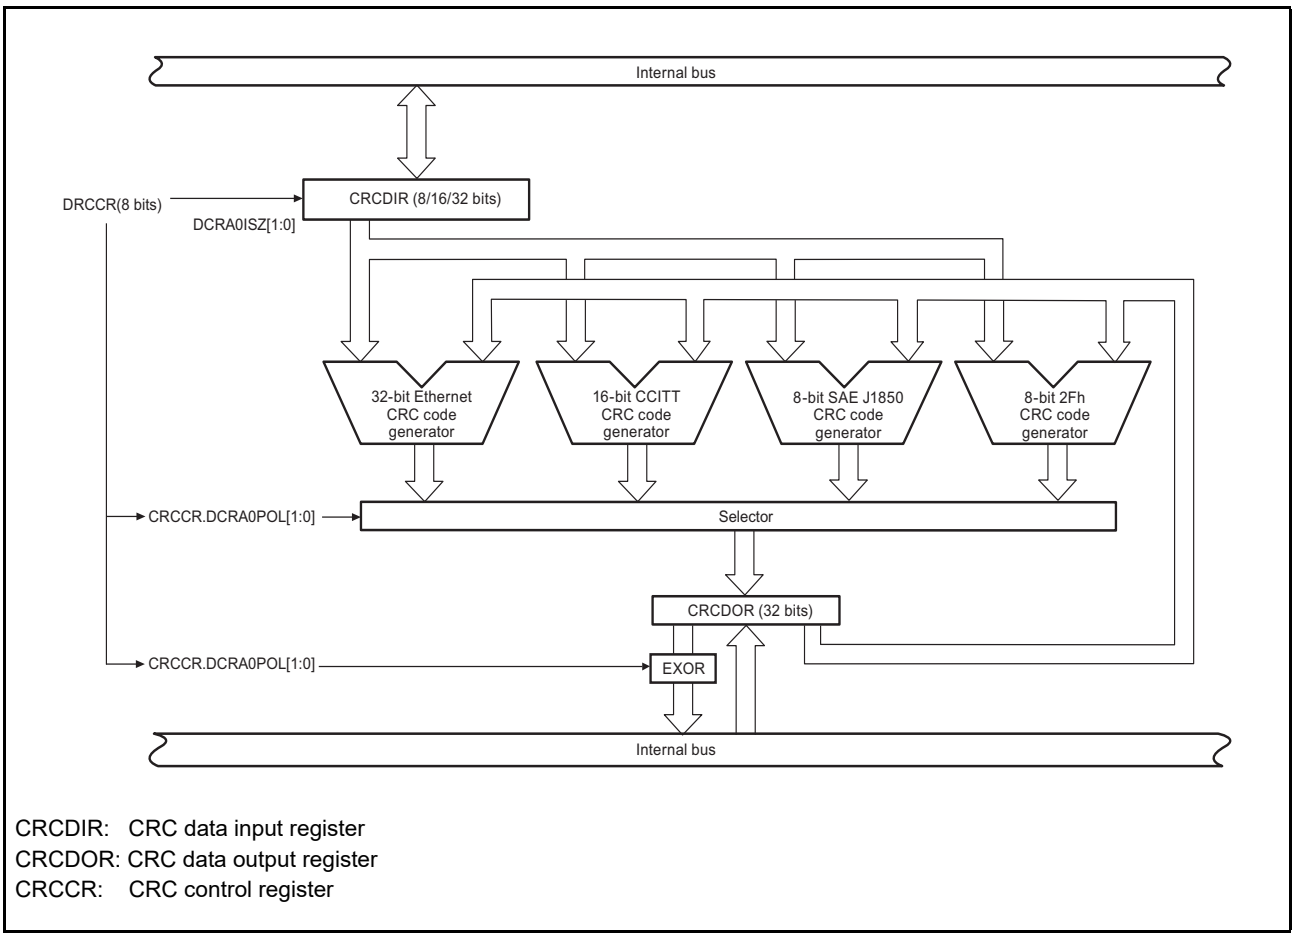

Figure 38.1 Block Diagram of a CRC Operation Unit (CRC)

38.2 Register Descriptions

38.2.1 CRC Data Input Register (CRCDIR)

The CRCDIR register stores the input data for CRC calculation. CRC calculation starts when data is written to this register.

The valid bit width used for CRC calculation must be set for CRCCR.DCRA0ISZ[1:0]. Before the first data is written to this register, the CRCDOR register must be initialized by writing the initial starting value. For details on initialization, see section 38.3.1, Initializing the CRC Data Output Register (CRCDOR).

Address(es): A007 C000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	CRCDIR[31:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CRCDIR[31:0]	Input Data for CRC Calculation	The following bit widths are supported: • CRC input bit width of 32 bits: CRCDIR[31:0] • CRC input bit width of 16 bits: CRCDIR[15:0] • CRC input bit width of 8 bits: CRCDIR[7:0]	R/W

Byte order

The byte order of the CRCDIR register differs depending on the selected CRC generation method.

- If the 32-Ethernet CRC polynomial expression is used to generate a code (CRCCR.DCRA0POL[1:0] = 00b), the LSB-first order is used (LSB: least significant byte). For example, if the CRC input bit width is 8 bits (DCRA0ISZ[1:0] = 10b), the bits 7 to 0 of the CRCDIR register are the LSB.
- If the 16-CCITT CRC polynomial expression is used to generate a code (CRCCR.DCRA0POL[1:0] = 01b), the MSB-first order is used (MSB: most significant byte). For example, if the CRC input bit width is 8 bits (DCRA0ISZ[1:0] = 10b), the bits 7 to 0 of the CRCDIR register are the MSB.
- If the 8-SAE J1850 CRC polynomial expression is used to generate a code (CRCCR.DCRA0POL[1:0] = 10b), the MSB-first order is used (MSB: most significant byte). For example, if the CRC input bit width is 8 bits (DCRA0ISZ[1:0] = 10b), the bits 7 to 0 of the CRCDIR register are the MSB.
- If the 8-0x2F CRC polynomial expression is used to generate a code (CRCCR.DCRA0POL[1:0] = 11b), the MSB-first order is used (MSB: most significant byte). For example, if the CRC input bit width is 8 bits (DCRA0ISZ[1:0] = 10b), the bits 7 to 0 of the CRCDIR register are the MSB.

38.2.2 CRC Data Output Register (CRCDOR)

The CRCDOR register stores the CRC code calculated based on the selected CRC generation polynomial expression.

Address(es): A007 C004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	CRCDOR[31:0]															
Value after reset:	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CRCDOR[31:0]															
Value after reset: *1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

Note 1. After a reset, 32-bit Ethernet CRC is selected as the CRC generation polynomial expression. Therefore, when the bits are read, 0000 0000h is obtained as the result of EXOR operation.

Bit	Symbol	Bit Name	Description	R/W
b31 to b0	CRCDOR[31:0]	Resulting CRC Code	• 32-Ethernet: CRCDOR[31:0] • 16-CCITT: CRCDOR[15:0] (Bits 31 to 16 are undefined.) • 8-SAE J1850/8-0x2F: CRCDOR[7:0] (Bits 31 to 8 are undefined.) The value read from this register is the result of EXOR operation with the following value: • 32-Ethernet: FFFF FFFFh • 16-CCITT: 0000h • 8-SAE J1850/8-0x2F: FFh	R/W

Note: This register must be initialized (by setting the initial starting value) before the first data for CRC calculation is written to the CRCDIR register. For details on initialization, see section 38.3.1, Initializing the CRC Data Output Register (CRCDOR).

CRCDOR[31:0] Bits

The CRC code calculated based on the CRC generation polynomial expression selected by CRCCR.DCRA0POL[1:0] is stored.

Resulting CRC code:

- If 32-Ethernet is used, the resulting CRC code is returned to CRCDOR[31:0].
- If 16-CCITT is used, the resulting CRC code is returned to CRCDOR[15:0].
  The settings of bits 31 to 16 are undefined.
- If 8-SAE J1850/8-0x2F is used, the resulting CRC code is returned to CRCDOR[7:0].
  The settings of bits 31 to 8 are undefined.

The value read from the bits is the result of EXOR operation with the following EXOR value:

EXOR value:

- 32-Ethernet: FFFF FFFFh
- 16-CCITT: 0000h
- 8-SAE J1850/8-0x2F: FFh

After a reset, 32-bit Ethernet is selected as the CRC generation polynomial expression. Therefore, when the bits are read, 0000 0000h is obtained as the result of EXOR operation of FFFF FFFFh (initial value stored in the bits) and FFFF FFFFh (EXOR value).

Example:

Assume that the value of the CRCDOR[31:0] bits is 5555 5555h as the CRC code produced by the 32-bit Ethernet CRC algorithm. In this case, when these bits are read, AAAA AAAAh is obtained as the result of EXOR operation with the EXOR value for this algorithm, i.e. FFFF FFFFh.

38.2.3 CRC Control Register (CRCCR)

The CRCCR register controls the CRC generation polynomial expression and the CRC input bit width.

Address(es): A007 C020h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	DCRA0ISZ[1:0]		—	—	DCRA0POL[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	DCRA0POL [1:0]	CRC Generation Mode Specification	Specify the mode in which to generate a CRC code. b1 b0 0 0: 32-Ethernet ($X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1$) 0 1: 16-CCITT ($X^{16} + X^{12} + X^5 + 1$) 1 0: 8-SAE J1850 ($X^8 + X^4 + X^3 + X^2 + 1$) 1 1: 8-0x2F ($X^8 + X^5 + X^3 + X^2 + X + 1$)	R/W
b3, b2	—	Reserved	These bits are read as 0.	R
b5, b4	DCRA0ISZ [1:0]	CRC Input Bit Width Specification	Specify the CRC input bit width. b1 b0 0 0: 32 bits (CRCDIR[31:0]) 0 1: 16 bits (CRCDIR[15:0]) 1 0: 8 bits (CRCDIR[7:0]) 1 1: Setting prohibited	R/W
b7, b6	—	Reserved	These bits are read as 0.	R

Note 1. If the CRC generation mode (CRCCR.DCRA0POL) is changed or the CRC input bit width (CRCCR.DCRA0ISZ) is changed, the CRCDOR register must be initialized (by setting the initial starting value). For details, see section 38.3.1, Initializing the CRC Data Output Register (CRCDOR).

Note 2. The CRC input bit width (CRCCR.DCRA0ISZ[1:0]) must be set according to the block unit of data for CRC calculation. The CRC input bit width must not be changed during CRC calculation. The CRC input bit width can be changed after the final CRC calculation result is read from the CRCDOR register. In this case, before the next data for CRC calculation is written to the CRCDIR register, the CRCDOR register must be initialized (by setting the initial starting value).

38.3 Operation

The CRC operation unit calculates and generates the CRC code for a block of a specific length. Data for which the CRC is to be calculated can be set in the CRC data input register (CRCDIR) in 8-, 16-, or 32- bit units. When data are written to the CRC data input register (CRCDIR), CRC calculation based on the selected CRC generation polynomial expression starts. Before writing the first value to the CRC data input register (CRCDIR), the CRCDOR register must be initialized by setting it to its initial value.
The following shows an overview of using the CRC operation unit.

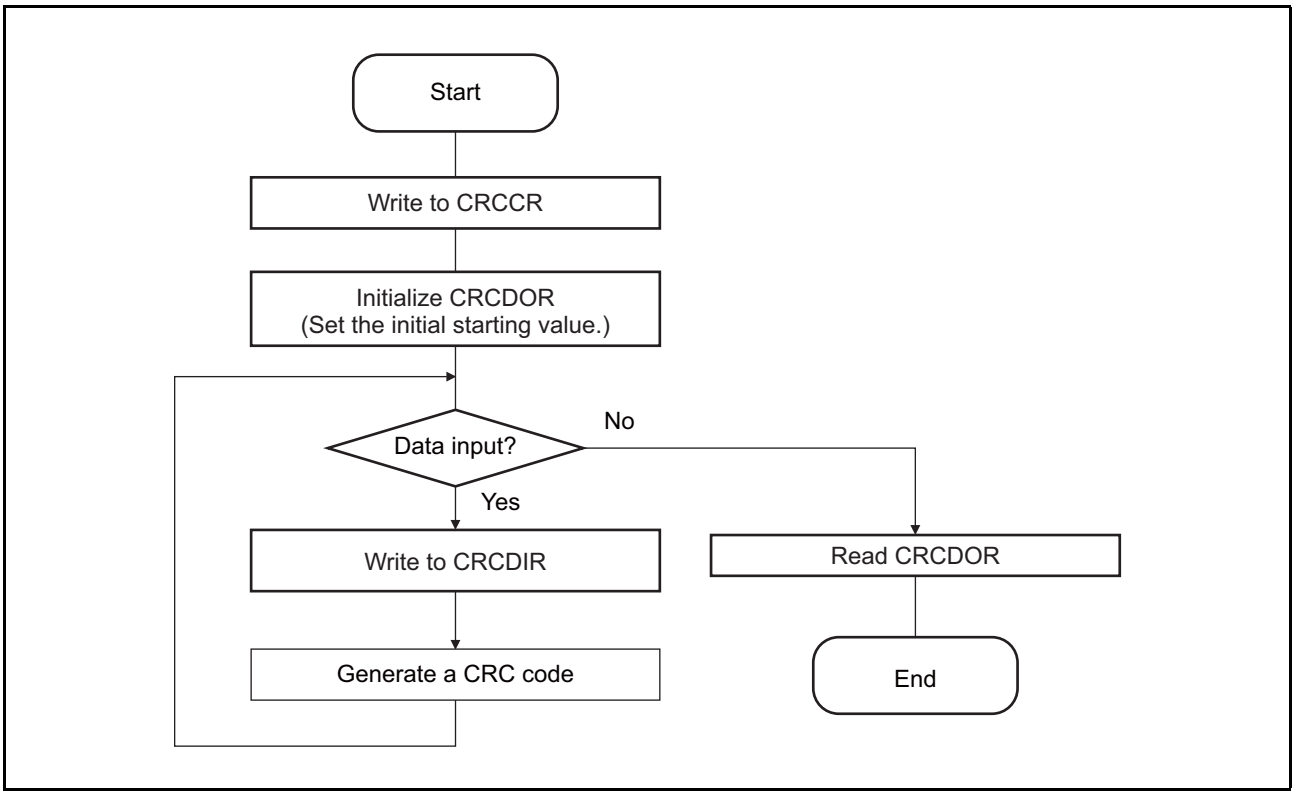

Figure 38.2 Use of the CRC Operation Unit

Note: If the CRC generation polynomial expression is changed by changing the value of CRCCR.DCRA0POL[1:0], the CRC data output register (CRCDOR) must be re-initialized (by setting the initial starting value).

38.3.1 Initializing the CRC Data Output Register (CRCDOR)

Before the first data is written to the CRC data input register (CRCDIR), the CRC data output register (CRCDOR) must be initialized by setting the initial starting value. Table 38.2 lists the initial starting value for each CRC generation polynomial expression.

Table 38.2 also shows the value obtained from the CRCDOR register after the initial starting value is set, as well as the EXOR value used for EXOR operation during a read. For details on the value obtained from the CRCDOR register, see section 38.2.2, CRC Data Output Register (CRCDOR).

Table 38.2 Initial Starting Value for Each CRC Generation Polynomial Expression

CRC Generation Polynomial Expression	Initial Starting Value	EXOR Value	Value Obtained from CRCDOR after the Initial Starting Value Is Set
32-Ethernet (DCRA0POL[1:0] = 00b)	FFFF FFFFh	FFFF FFFFh	0000 0000h
16-CCITT (DCRA0POL[1:0] = 01b)	0000 FFFFh	0000 0000h	0000 FFFFh
8-SAE J1850 (DCRA0POL[1:0] = 10b)	0000 00FFh	0000 00FFh	0000 0000h
8-0x2F (DCRA0POL[1:0] = 11b)	0000 00FFh	0000 00FFh	0000 0000h

39. Serial Sound Interface (SSI)

This LSI integrates one channel of the serial sound interface (SSI) compliant to the I^{2}S bus standard. The SSI supports I^{2}S bus compatibility and MSB-first and left-aligned/right-aligned formats, so it can be used to send or receive audio data with various devices.

39.1 Overview

Table 39.1 SSI Specifications

Item	Specifications
Number of channels	One channel
Operating mode	Non-compressed mode
Transfer formats	• I^{2}S format supported • MSB-first supported Left-aligned/right-aligned formats selectable
Function	• Serves as both a transmitter and a receiver Supports full-duplex communications. • Capable of various audio formats • SSISCK (serial bit clock) can be selected from among 16, 32, 48, and 64 fs (fs: Sampling rate) • Master clock is input from the external clock for SSI (AUDIO_CLK) (Max. 50 MHz) • Includes 8-stage FIFO buffers in transmitter and receiver • Capable of selecting whether to stop word select (SSIWS) or not when data transfer is stopped
Interrupt sources	Three sources • Communication error Transmit underflow, transmit overflow, receive underflow, receive overflow, and idle • Receive data full • Transmit data empty
Low-power consumption function	Module stop state can be set.

Figure 39.1 shows a block diagram of SSI.

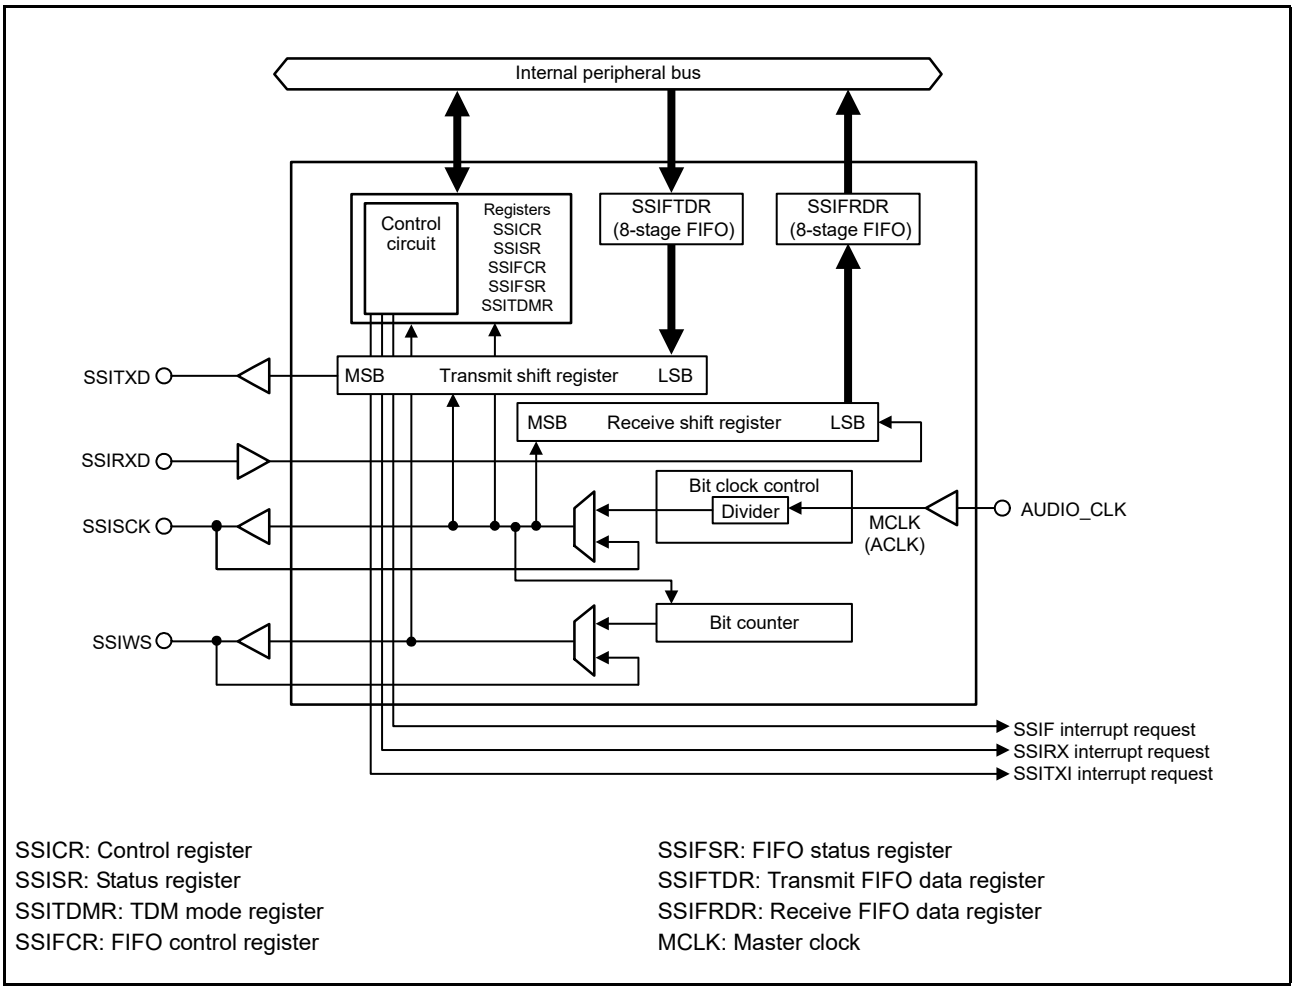

Figure 39.1 Block Diagram of SSI

Table 39.2 lists the I/O pins of the SSI.

Table 39.2 SSI I/O Pins

Pin Name	I/O	Description
SSISCK	I/O	Serial bit clock pin
SSIWS	I/O	Word selection pin
SSITXD	Output	Serial data output pin
SSIRXD	Input	Serial data input pin
AUDIO_CLK	Input	Master clock for audio pin (input master clock)

39.2 Register Description

39.2.1 Control Register (SSICR)

The SSICR register controls the operating mode, polarity setting, and various interrupts.

Address(es): A008 1000h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

b28	TOIEN	Transmit FIFO Overflow Interrupt Enable	0: Disables a transmit FIFO overflow interrupt. 1: Enables a transmit FIFO overflow interrupt.	R/W
b29	TUIEN	Transmit FIFO Underflow Interrupt Enable	0: Disables a transmit FIFO underflow interrupt. 1: Enables a transmit FIFO underflow interrupt.	R/W
b30	CKS	Audio Clock Select*3	0: AUDIO_CLK input 1: Setting prohibited	R/W
b31	—	Reserved	This bit is read as undefined. The write value should be 0.	R/W

b13 SCKP:

	SCKP bit = 0	SCKP bit = 1
SSITXD/SSIRXD input sampling timing for reception	SSISCK rising edge	SSISCK falling edge
SSITXD/SSIRXD output changing timing for transmission	SSISCK falling edge	SSISCK rising edge
SSIWS input sampling timing in slave mode (SWSD bit = 0)	SSISCK rising edge	SSISCK falling edge
SSIWS output changing timing in master mode (SWSD bit = 1)	SSISCK falling edge	SSISCK rising edge

Note 1. While this module is muted, 0 is transmitted regardless of the value of serial data, but data transfer is not stopped. Since the number of data in the transmit FIFO decreases, write dummy data to the SSIFTDR register to prevent the generation of a transmit underflow. When the MUEN bit is set to 1, the SSITXD pin is immediately set to 0 without synchronizing SSIWS.
Note 2. Set the SCKD and SWSD bits to the same value. Other settings are prohibited.
Note 3. Rewriting is allowed only in the idle state.

REN Bit (Receive Enable)

This bit enables or disables receive operation. Setting this bit to 1 starts receive operation.

TEN Bit (Transmit Enable)

This bit enables or disables transmit operation. Setting this bit to 1 starts transmit operation.
SSITXD of SSI is set as output while the I/O port function is selected, regardless of the TEN bit setting.

Table 39.3 SSITXD and SSIRXD Pin States

	Register Settings		SSI	
MPC setting	TEN	REN	SSITXD	SSIRXD
SSI selected	0	0	Output	Input
	0	1	Output	Input
	1	0	Output	Input
	1	1	Output	Input
SSI deselected	x	x	I/O port	I/O port

x: Don't care
I/O port: Depends on the settings of the I/O port and multi-function pin controller.

CKDV[3:0] Bits (Serial Bit Clock Frequency Setting)

These bits are used to select a division ratio of the master clock to set the serial bit clock frequency in the master mode. Since the input clock from the SSISCK pin is used in slave mode, the setting of these bits is ignored. The serial bit clock is used as the operating clock of the shift register.

Calculation Example:
When fs (sampling rate) = the SSIWS frequency = 96 kHz and the system word length = 32 bits
The bit clock frequency = 96 kHz × 32 bits × 2 = 6.144 MHz is necessary, so set CKDV[3:0] = 0001b when MCLK = 12.288 MHz.

PDTA Bit (Parallel Data Allocation)

The setting of this bit specifies the allocation of data to be stored in the SSIFRDR register in reception mode and the SSIFTDR register in transmission mode.

During receive operation, the SSI stores the data received from the serial audio bus in SSIFRDR according to the PDTA bit setting.

During transmit operation, the SSI stores the data stored in SSIFTDR in the transmit shift register, and transmits the data to the audio serial bus according to the PDTA bit setting.

When PDTA = 0

DWL[2:0] Bits	SSIFTDR/SSIFRDR[31:0] Registers
000b	31 24 23 16 15 8 7 0 4th word | 3rd word | 2nd word | 1st word
001b	31 16 15 0 2nd word | 1st word
010b	31 14 13 0 Valid | Invalid
011b	31 12 11 0 Valid | Invalid
100b	31 10 9 0 Valid | Invalid
101b	31 8 7 0 Valid | Invalid

When PDTA = 1

DWL[2:0] Bits	SSIFTDR/SSIFRDR[31:0] Registers
000b	31 24 23 16 15 8 7 0 1st word | 2nd word | 3rd word | 4th word
001b	31 16 15 0 1st word | 2nd word
010b	31 18 17 0 Invalid | Valid
011b	31 20 19 0 Invalid | Valid
100b	31 22 21 0 Invalid | Valid
101b	31 24 23 0 Invalid | Valid

CHNL[1:0] Bits (Channels)

These bits select the number of channels in the system word. Set these bits to 00b.

39.2.2 Status Register (SSISR)

The SSISR register indicates the operating status of SSI.

Address(es): A008 1004h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	x	x	x	x	x	x	x	x	x	0	0	1	0	0	1	1

x: Undefined

Bit	Symbol	Bit Name	Description	R/W
b0	IDST	Idle Status Flag	0: SSI communication is in progress. 1: SSI communication is idle.	R
b1	RSWNO	Receive System Word Number	Receive word number	R
b3, b2	—	Reserved	These bits are read as 00b.	R
b4	TSWNO	Transmit System Word Number	Transmit word number	R
b6, b5	—	Reserved	These bits are read as 00b.	R
b24 to b7	—	Reserved	These bits are read as undefined.	R
b25	IIRQ	Idle Interrupt Status Flag	0: Not in idle state 1: In idle state	R
b26	ROIRQ	Receive Overflow Interrupt Status Flag	0: No receive overflow has occurred. 1: A receive overflow has occurred.	R/(W) *1
b27	RUIRQ	Receive Underflow Interrupt Status Flag	0: No receive underflow has occurred. 1: A receive underflow has occurred.	R/(W) *1
b28	TOIRQ	Transmit Overflow Interrupt Status Flag	0: No transmit overflow has occurred. 1: A transmit overflow has occurred.	R/(W) *1
b29	TUIRQ	Transmit Underflow Interrupt Status Flag	0: No transmit underflow has occurred. 1: A transmit underflow has occurred.	R/(W) *1
b31, b30	—	Reserved	These bits are read as undefined.	R

Note 1. This bit can be set to 0 by writing 0 after reading it as 1.

IDST Flag (Idle Status Flag)

This status flag indicates that the SSI is in idle state where communication is stopped.

This flag is set to 0 when communication starts after the SSICR.TEN bit or SSICR.REN bit is set to 1. Also, this flag is set to 1 if both the SSICR.TEN and SSICR.REN bits are set to 0 and system word communication is completed.

If the external device stops inputting the serial bit clock before communication is completed, this flag is not set to 1.

RSWNO Bit (Receive System Word Number)

The initial value of this bit is 1, and its value is inverted when the data is transferred from the receive shift register to the SSIFRDR register.

This bit is initialized to 1 when the REN bit value is changed from 0 to 1.

When the data word length specified by the SSICR.DWL[2:0] bits is 18 bits or more, this bit indicates which system word the data in the SSIFRDR register represents.

TSWNO Bit (Transmit System Word Number)

This status bit indicates the current word number.
The initial value of this is 1, and its value is inverted when the data is transferred from the SSIFTDR register to the transmit shift register.
This bit is initialized to 1 when the TEN bit value is changed from 0 to 1.
When the data word length specified by the SSICR.DWL[2:0] bits is 18 bits or more, this bit indicates the system word that is in the data transferred from the SSIFTDR register to the transmit shift register.

IIRQ Flag (Idle Interrupt Status Flag)

This status flag indicates whether this module is in idle state.
This flag is set regardless of the value of the SSICR.IIEN bit to allow polling.
The interrupt can be masked by setting the SSICR.IIEN bit to 0, but cannot be cleared by writing to this flag.
If IIRQ flag = 1 and SSICR.IIEN bit = 1, an interrupt occurs.

ROIRQ Flag (Receive Overflow Interrupt Status Flag)

This status flag indicates that receive data was supplied at a higher rate than was required. If a receive overflow occurs, stop reception and start from the beginning of the flowchart again.
This flag is set to 1 regardless of the setting of the SSICR.ROIEN bit. This flag can be set to 0 by writing 0 after reading it as 1.
If ROIRQ flag = 1 and SSICR.ROIEN bit = 1, an interrupt occurs.
The ROIRQ flag being 1 indicates that the data has been transferred from the receive shift register to the SSIFRDR register before the previous unread data is read out while the receive FIFO is full (SSIFSR.RDC[3:0] flag = 8h). This may lead to the loss of data.

Note: When an overflow occurs, the current data in the data buffer of this module is overwritten by the next incoming data from the SSI interface.

RUIRQ Flag (Receive Underflow Interrupt Status Flag)

This status flag indicates that receive data was supplied at a lower rate than was required. If a receive underflow occurs, stop reception and start the flowchart again from the beginning.
This flag is set to 1 regardless of the setting of the SSICR.RUIEN bit. This flag can be set to 0 by writing 0 after reading it as 1.
If RUIRQ flag = 1 and SSICR.RUIEN bit = 1, an interrupt occurs.
If RUIRQ flag = 1, the SSIFRDR register was read while the receive FIFO is empty (SSIFSR.RDC[3:0] flags = 0h). This may cause invalid receive data to be stored.

TOIRQ Flag (Transmit Overflow Interrupt Status Flag)

This status flag indicates that transmit data was supplied at a higher rate than was required. If a transmit overflow occurs, stop transmission and start from the beginning of the flowchart again.
This flag is set to 1 regardless of the setting of the SSICR.TOIEN bit. This flag can be set to 0 by writing 0 after reading it as 1.
If TOIRQ flag = 1 and SSICR.TOIEN bit = 1, an interrupt occurs.
If TOIRQ flag = 1, the SSIFTDR register had data written to it while the transmit FIFO is full (SSIFSR.TDC[3:0] flags = 8h). This may lead to the loss of data.

TUIRQ Flag (Transmit Underflow Interrupt Status Flag)

This status flag indicates that transmit data was supplied at a lower rate than was required. If a transmit underflow occurs, stop transmission and start from the beginning of the flowchart again.

This flag is set to 1 regardless of the setting of the SSICR.TUIEN bit. This flag can be set to 0 by writing 0 after reading it as 1.

If TUIRQ flag = 1 and SSICR.TUIEN bit = 1, an interrupt occurs.

If TUIRQ flag = 1, the SSIFTDR register did not have data written to it before it was required for transmission. This may lead to the same data being transmitted once more.

Note: When a transmit underflow occurs, the last data input to SSIFTDR is transmitted until this module is in the idle state after transmission is stopped.

39.2.3 FIFO Control Register (SSIFCR)

The SSIFCR register controls settings of the transmit FIFO register and the receive FIFO register.

Address(es): A008 1010h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	AUCKE	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

b7, b6	TTRG[1:0]	Transmit FIFO Threshold Setting Trigger*4	b7 b6 0 0: 7 (1)*3 0 1: 6 (2)*3 1 0: 4 (4)*3 1 1: 2 (6)*3	R/W
b30 to b8	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b31	AUCKE	Master Clock Enable*4	0: The master clock is disabled. 1: The master clock is enabled.	R/W

Note 1. The RXI request can be cleared by setting the SSIFSR.RDF flag to 0 (see the description of the SSIFSR.RDF flag for details) or RIE bit to 0.
Note 2. The TXI request can be cleared by setting the SSIFSR.TDE flag to 0 (see the description of the SSIFSR.TDE flag for details) or TIE bit to 0.
Note 3. The values in parenthesis are the number of empty stages in SSIFTDR at which the SSIFSR.TDE flag is set.
Note 4. Rewriting is allowed only in the idle state.

The SSIFCR register resets the number of the data bytes stored in the SSIFTDR and SSIFRDR registers, and specifies transmit FIFO and receive FIFO threshold values.

RFRST Bit (Receive FIFO Data Register Reset)

This bit invalidates the data in the SSIFRDR register to reset the FIFO to an empty state.

TFRST Bit (Transmit FIFO Data Register Reset)

This bit invalidates the data in the SSIFTDR register to reset the FIFO to an empty state.

RIE Bit (Receive FIFO Data Full Interrupt Enable)

This bit enables or disables generation of receive FIFO data full interrupt (RXI) requests when the SSIFSR.RDF flag is set to 1 during reception.

TIE Bit (Transmit FIFO Data Empty Interrupt Enable)

This bit enables or disables generation of transmit FIFO data empty interrupt (TXI) requests when the SSIFSR.TDE flag is set to 1 during transmit operation.

RTRG[1:0] Bits (Receive FIFO Threshold Setting Trigger)

These bits specify the receive FIFO threshold value. When the number of received data bytes stored in the SSIFRDR register (receive FIFO) has become equal to or greater than the value specified by the RTRG[1:0] bits, the SSIFSR.RDF flag is set to 1 and reading the received data is requested. If the SSIFCR.RIE bit is 1 at this time, a receive FIFO data full interrupt (RXI) request is generated.

TTRG[1:0] Bits (Transmit FIFO Threshold Setting Trigger)

These bits specify the transmit FIFO threshold value. When the number of transmit data bytes stored in the SSIFTDR register (transmit FIFO) has become equal to or less than the value specified by the TTRG[1:0], the SSIFSR.TDE flag is set to 1 and writing the transmit data is requested. If the SSIFCR.TIE bit is 1 at this time, a transmit FIFO data empty interrupt (TXI) request is generated.

39.2.4 FIFO Status Register (SSIFSR)

The SSIFSR register indicates the operating status of the SSIFTDR register and the SSIFRDR register.

Address(es): A008 1014h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	TDC[3:0]				—	—	—	—	—	—	—	TDE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	RDC[3:0]				—	—	—	—	—	—	—	RDF
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	RDF	Receive Data Full Flag	0: Number of received data bytes in the SSIFRDR register is less than the set receive trigger number. 1: Number of received data bytes in the SSIFRDR register is equal to or greater than the set receive trigger number.	R/(W) *1
b7 to b1	—	Reserved	These bits are read as 0.	R
b11 to b8	RDC[3:0]	Receive Data Indicate Flag	Indicate the number of data units stored in the SSIFRDR register.	R
b15 to b12	—	Reserved	These bits are read as 0.	R
b16	TDE	Transmit Data Empty Flag	0: Number of data bytes for transmission in the SSIFTDR register is greater than the set transmit trigger number. 1: Number of data bytes for transmission in the SSIFTDR register is equal to or less than the set transmit trigger number.*2	R/(W) *1
b23 to b17	—	Reserved	These bits are read as 0.	R
b27 to b24	TDC[3:0]	Transmit Data Indicate Flag	Indicate the number of data units stored in the SSIFTDR register.	R
b31 to b28	—	Reserved	These bits are read as 0.	R

Note 1. This bit can be set to 0 by writing 0 after reading it as 1.
Note 2. Since the SSIFTDR register is an 8-stage FIFO register, the amount of data that can be written to it while TDE flag = 1 is “8 - transmit trigger number to be specified” bytes at maximum. Writing more data will be ignored. The number of data bytes in the SSIFTDR register is indicated in the TDC[3:0] flags.

RDF Flag (Receive Data Full Flag)

This flag indicates that, when the received data is transferred to the SSIFRDR register, the number of data bytes in the SSIFRDR register has become equal to or greater than the receive FIFO threshold value, and thus reading the received data from the SSIFRDR register has been enabled.

[Setting condition]

- The number of receive data bytes that is equal to or greater than the receive FIFO threshold value is stored in the SSIFRDR register.*1

[Clearing condition]

- 0 is written to the RDF flag after the RDF flag is confirmed to be 1.

Note 1. Since the SSIFRDR register is a 32-byte FIFO register, the maximum number of data bytes that can be read from it while the RDF flag is 1 is indicated in the RDC[3:0] flags. If reading data from the SSIFRDR register is continued after all the data is read, undefined values will be read.

RDC[3:0] Flags (Receive Data Indicate Flag)

These flags indicate the number of data bytes stored in the SSIFRDR register.
RDC[3:0] flags = 0h indicates no received data. RDC[3:0] flags = 8h indicates that 32 bytes of received data is stored in the SSIFRDR register.

TDE Flag (Transmit Data Empty Flag)

This flag indicates that, when data is transferred from the SSIFTDR register to the transmit shift register, the number of data bytes in the SSIFTDR register has become less than the transmit FIFO threshold value, and thus writing transmit data to the SSIFTDR register has been enabled.
[Setting condition]

- The number of the transmit data bytes written to the SSIFTDR register is equal to or less than the transmit FIFO threshold value.*1

[Clearing condition]

- 0 is written to the TDE flag after the TDE flag is confirmed to be 1.

Note 1. Since the SSIFTDR register is a 32-bit FIFO register, the maximum number of bytes that can be written to it while the TDE flag is 1 is 8 - TDC[3:0]. If writing data to the SSIFTDR register is continued after all the data is written, writing will be invalid and an overflow occurs.

TDC[3:0] Flags (Transmit Data Indicate Flag)

These flags indicate the number of data bytes stored in the SSIFTDR register.
TDC[3:0] flags = 0h indicates no data for transmission. TDC[3:0] flags = 8h indicates that 32 bytes of data for transmission is stored in the SSIFTDR register.

39.2.5 Transmit FIFO Data Register (SSIFTDR)

The SSIFTDR register is a write-only FIFO register consisting of eight 32-bit stages for storing data to be serially transmitted.

Address(es): A008 1018h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Write transmit data to the SSIFTDR register in 64-bit (two-stage FIFO) units regardless of the data word length setting. If transmit data ends on a 32-bit boundary, write 32-bit 0-data (0000 0000h) after the last transmit data is written, and stop transmission while 64-bit writing is completed. When the transmit shift register is empty, the SSI transfers the transmit data written to the SSIFTDR register to start serial transmission, which can be continued until the SSIFTDR register becomes empty.

Note that when the SSIFTDR register is full of data (32 bytes), the next data cannot be written to it. If writing is attempted, it will be ignored and an overflow occurs.

39.2.6 Receive FIFO Data Register (SSIFRDR)

The SSIFRDR register is a read-only FIFO register consisting of eight 32-bit stages for storing serially received data.

Address(es): A008 101Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—

Each time 4 bytes of serial data is received, the SSI stores the received serial data in the SSIFRDR register from the receive shift register according to the PDTA bit setting. Receive operation can be continued until a maximum 32 bytes of data have been stored to in the SSIFRDR register. The SSIFRDR register can be read but cannot be written to. Note that when the SSIFRDR register is read when it stores no received data, undefined values will be read and a receive underflow occurs.

After the SSIFRDR register becomes full of received data, the data received thereafter will be lost and a receive overflow occurs.

39.2.7 TDM Mode Register (SSITDMR)

The SSITDMR register is a readable/writable 32-bit register that enables or disables WS continue mode.

Address(es): A008 1020h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CONT	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	CONT	WS Continue Mode*1	0: Disables WS continue mode. 1: Enables WS continue mode.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

Note 1. This bit can be set only in master mode (SSICR.SCKD bit = 1 and SSICR.SWSD bit = 1).

39.3 Operation

39.3.1 Bus Format

This module can operate as a transmitter or a receiver and can be configured into many serial bus formats in either mode. The bus format can be selected from one of the six modes shown in Table 39.4.

Table 39.4 Bus Format

	TEN	REN	SCKD	SWSD	MUEN	IIEN	TOIEN	TUIEN	ROIEN	RUIEN	CONT	SWSP	DEL	PDTA	SDTA	SPDP	SCKP	SWL[2:0]	DWL[2:0]	CHNL[1:0]
Non-Compression Slave Receiver	0	1	0	0	Control Bits							Configuration Bits								
Non-Compression Slave Transmitter	1	0	0	0																
Non-Compression Slave Transceiver	1	1	0	0																
Non-Compression Master Receiver	0	1	1	1																
Non-Compression Master Transmitter	1	0	1	1																
Non-Compression Master Transceiver	1	1	1	1																

39.3.2 Non-Compressed Mode

The non-compressed mode supports all serial audio streams split into channels. It supports the I^2S compatible format as well as MSB-first and left-aligned/right-aligned.

(1) Slave Receiver

This mode allows the module to receive serial data from another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(2) Slave Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(3) Slave Transceiver

This mode allows serial data transmission and reception between this module and another device. The clock and word select signal used for the serial data stream is also supplied from an external device. If these signals do not conform to the format specified in the configuration fields of this module, operation is not guaranteed.

(4) Master Receiver

This mode allows the module to receive serial data from another device. The clock and word select signals are internally derived from the master clock. The format of these signals is defined in the configuration fields of this module. If the incoming data does not follow the configured format, operation is not guaranteed.

(5) Master Transmitter

This mode allows the module to transmit serial data to another device. The clock and word select signals are internally derived from the master clock. The format of these signals is defined in the configuration fields of this module.

(6) Master Transceiver

This mode allows serial data transmission and reception between this module and another device. The clock and word select signals are internally derived from the master clock. The format of these signals is defined in the configuration fields of this module.

(7) Operating Setting Related to Word Length

All bits related to the SSICR register's word length are valid in non-compressed modes. There are many configurations this module supports, but some of the combinations are shown below for the I²S compatible format, MSB-first and left-aligned format, and MSB-first and right-aligned format.

- I²S Compatible Format

Figure 39.2 and Figure 39.3 show the I²S compatible format both without and with padding.
Padding occurs when the data word length is smaller than the system word length.

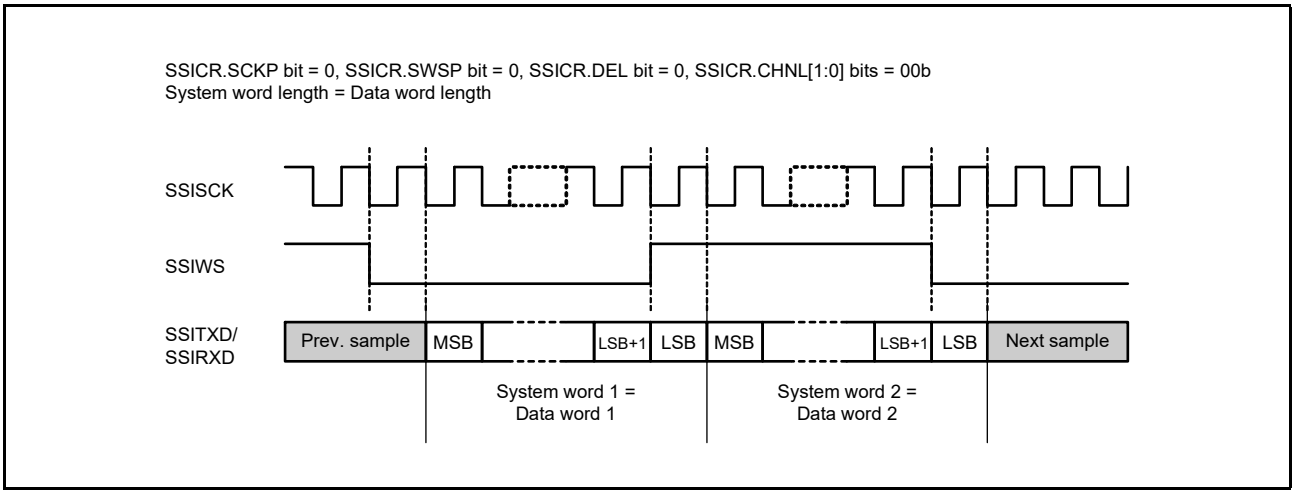

Figure 39.2 I²S Compatible Format (without Padding)

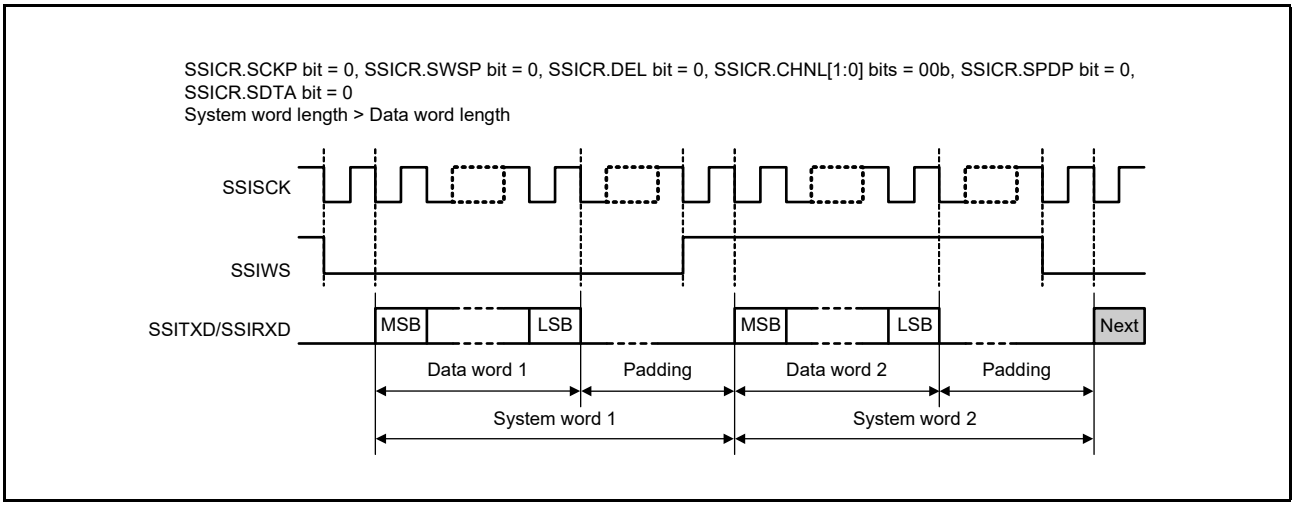

Figure 39.3 I²S Compatible Format (with Padding)

Figure 39.4 shows the MSB-first and left-aligned format and Figure 39.5 shows the MSB-first and right-aligned format.

- MSB-First and Left-Aligned Format

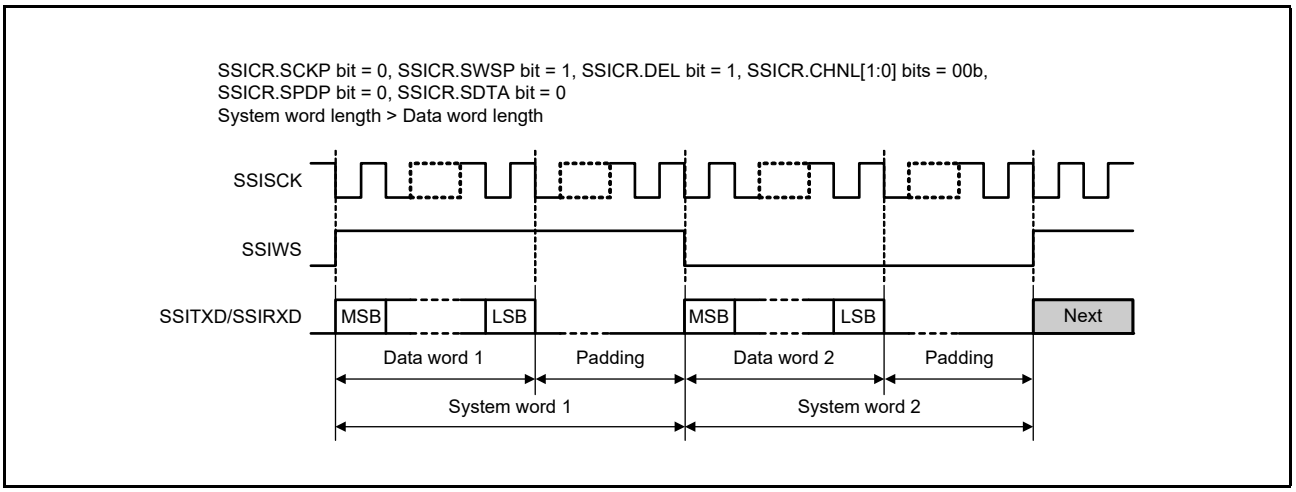

Figure 39.4 MSB-First and Left-Aligned Format (Transmitted and Received in the Order of Serial Data and Padding Bits)

- MSB-First and Right-Aligned Format

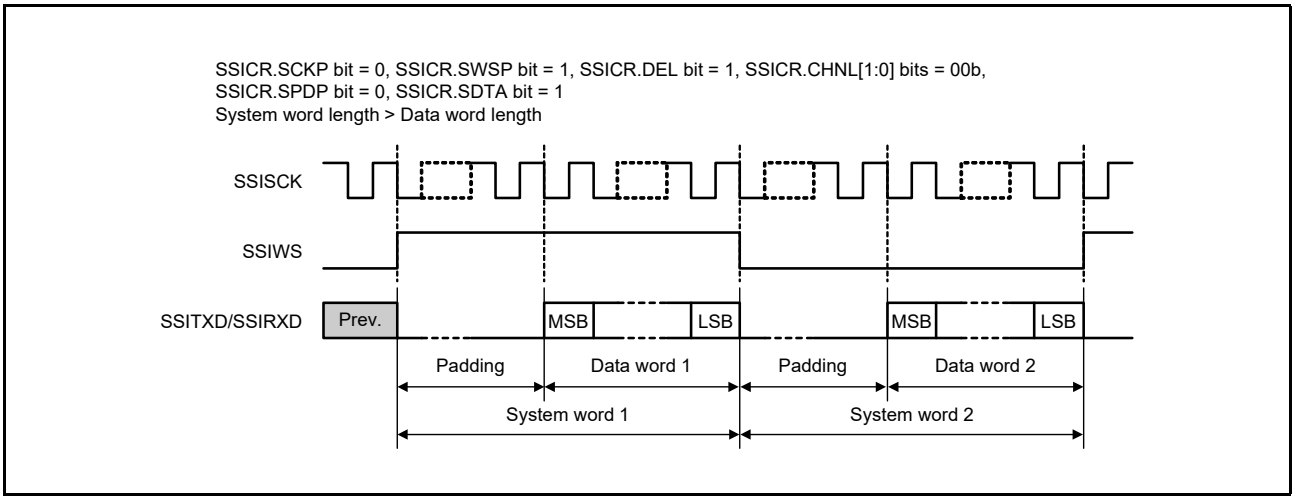

Figure 39.5 MSB-First and Right-Aligned Format (Transmitted and Received in the Order of Padding Bits and Serial Data)

Table 39.5 shows the number of padding bits for each of the valid setting.

Table 39.5 Number of Padding Bits for Each Valid Setting

Padding Bits per System Word			SSICR.DWL[2:0] Bits	000b	001b	010b	011b	100b	101b
SSICR.CHNL[1:0] Bits	Decoded Channels per System Word	SSICR.SWL[2:0] Bits	Data Word Length / System Word Length	8	16	18	20	22	24
00b	1	000b	8	0	—	—	—	—	—
		001b	16	8	0	—	—	—	—
		010b	24	16	8	6	4	2	0
		011b	32	24	16	14	12	10	8

(8) Operating Setting Format Configuration Bit

Several more configuration bits in non-compressed mode are shown below. These bits are not mutually exclusive, but some combinations may not be useful for any other device.

These configuration bits are described below with reference to the basic sample format in Figure 39.6.
In Figure 39.6 to Figure 39.14, a system word length of 6 bits and a data word length of 4 bits are used for simplification of these figures.

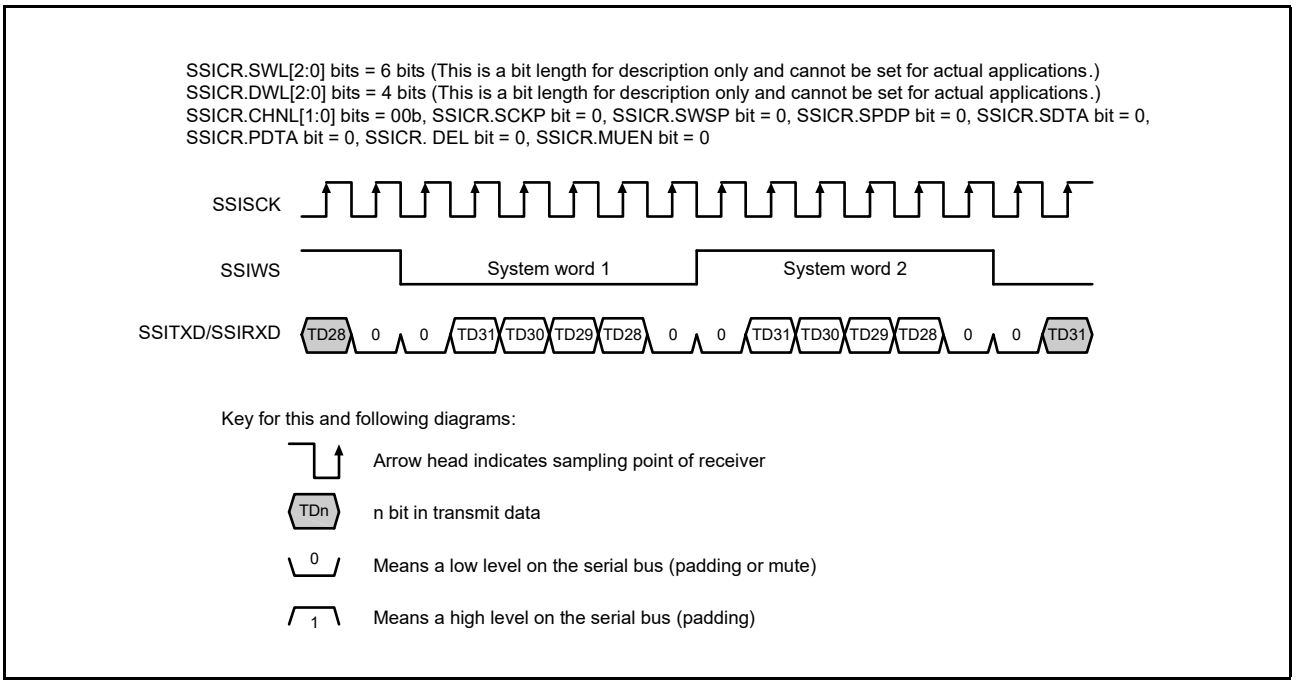

Figure 39.6 Basic Sample Format (Transmit Mode with Example System/Data Word Length)

- Parallel Right-Aligned with Delay

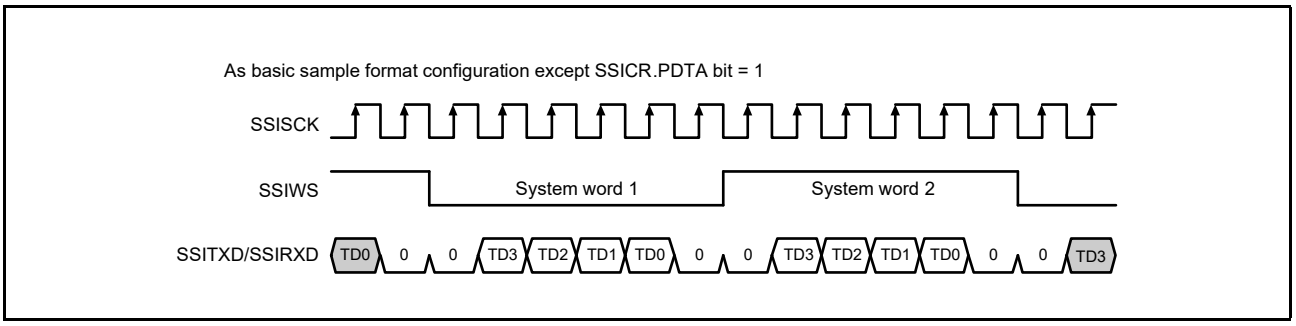

Figure 39.13 Parallel Right-Aligned with Delay

- Mute Enabled

When the SSICR.MUEN bit is set to 1, the SSITXD pin is set to 0 without synchronizing SSIWS.

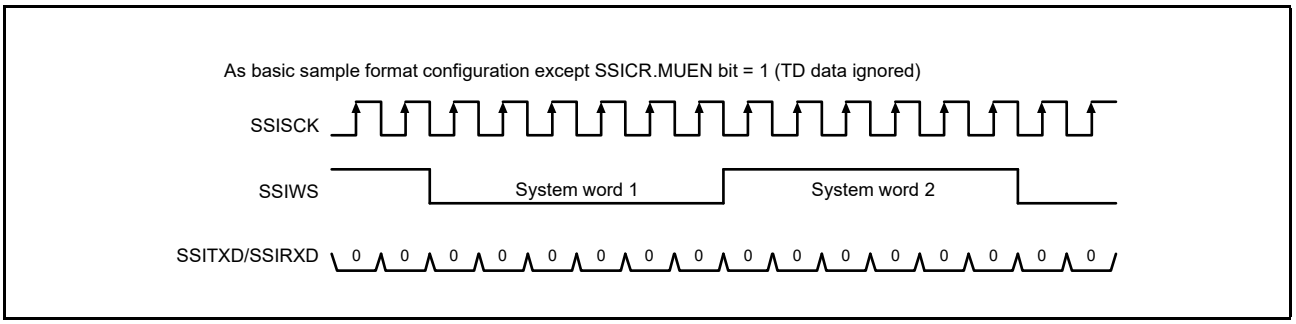

Figure 39.14 Mute Enabled

39.3.3 WS Continue Mode

In WS continue mode, the SSIWS signal continues to be output irrespective whether data transfer is enabled or disabled. This mode can be set using the SSITDMR.CONT bit. With this mode enabled, the SSIWS signal does not stop but continues operating even if the SSICR.TEN and REN bits are both set to 0 (transfer disabled). With this mode disabled, the SSIWS signal stops if the SSICR.TEN and REN bits are both set to 0.

Figure 39.15 and Figure 39.16 show the operations with WS continue mode enabled and disabled, respectively.

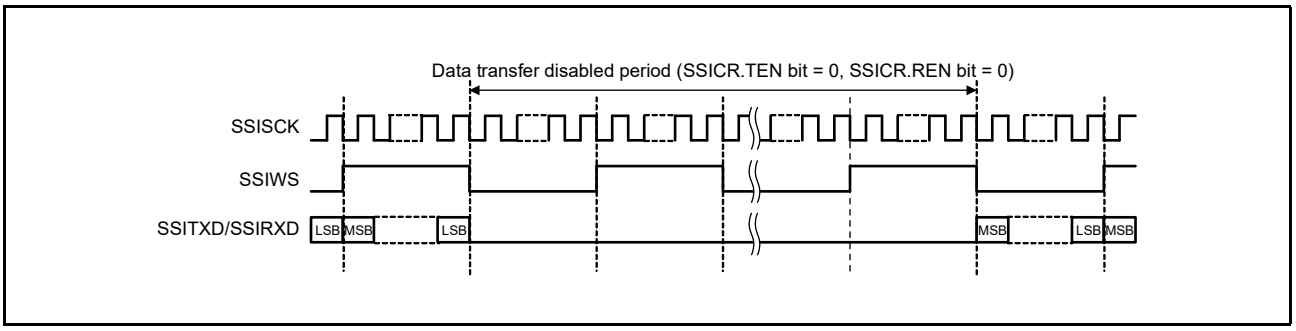

Figure 39.15 WS Continue Mode Enabled

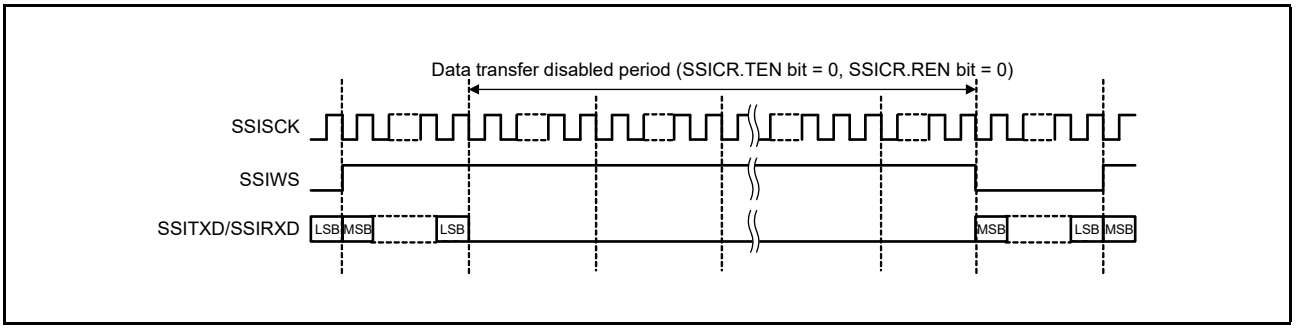

Figure 39.16 WS Continue Mode Disabled

39.3.4 Operating States

There are three states of operation: idle, communication, and waiting for idle. Figure 39.17 shows the operating state transitions.

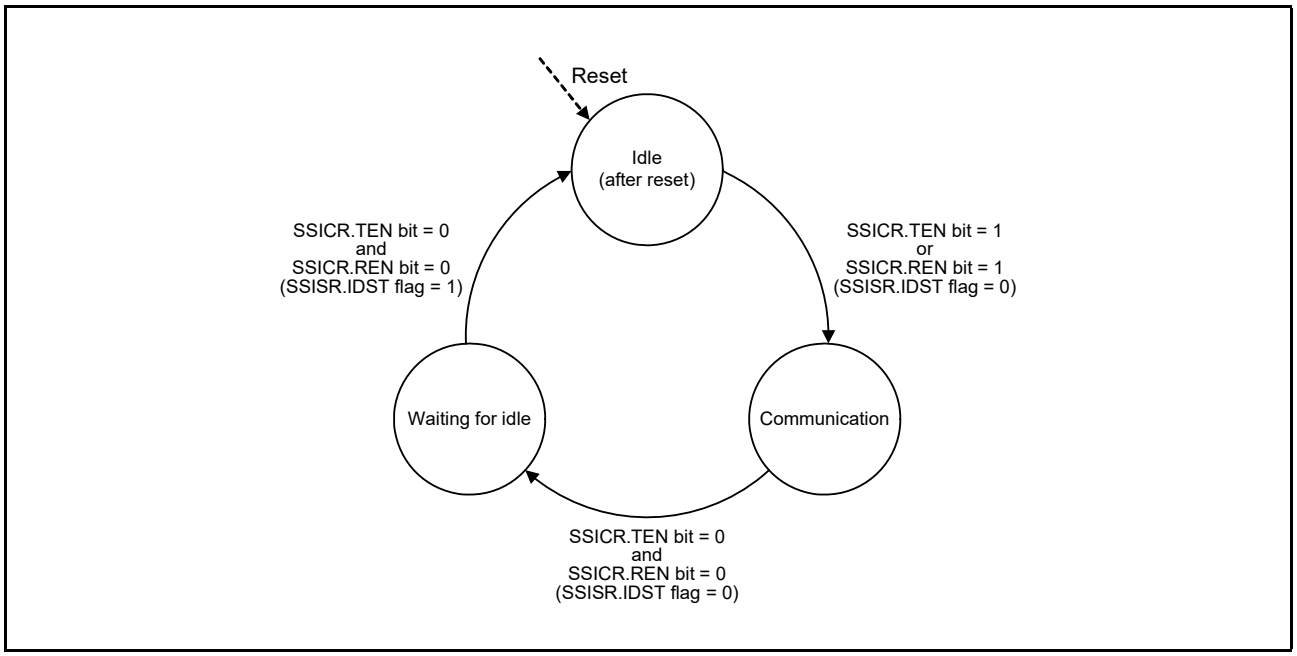

Figure 39.17 Operating State Transitions

(1) Idle State

This module enters this state when the MSTPCRD.MSTPD10, MSTPD11, and MSTPD15 bits are set to 0 after a reset is released. All required configuration fields in the control register should be defined in this state. After the settings are made, the module enters communication enabled state when the SSICR.TEN bit or SSICR.REN bit is set to 1.

(2) Communication State

Communication in this state depends on the selected operating state. For details, refer to section 39.3.5, Transmit Operation and section 39.3.6, Receive Operation.

(3) Waiting for Idle

This module enters this state when both the SSICR.TEN and SSICR.REN bits are set to 0 in communication state. If system word communication is completed in this state, the SSISR.IDST flag is set to 1 and this module enters the idle state.

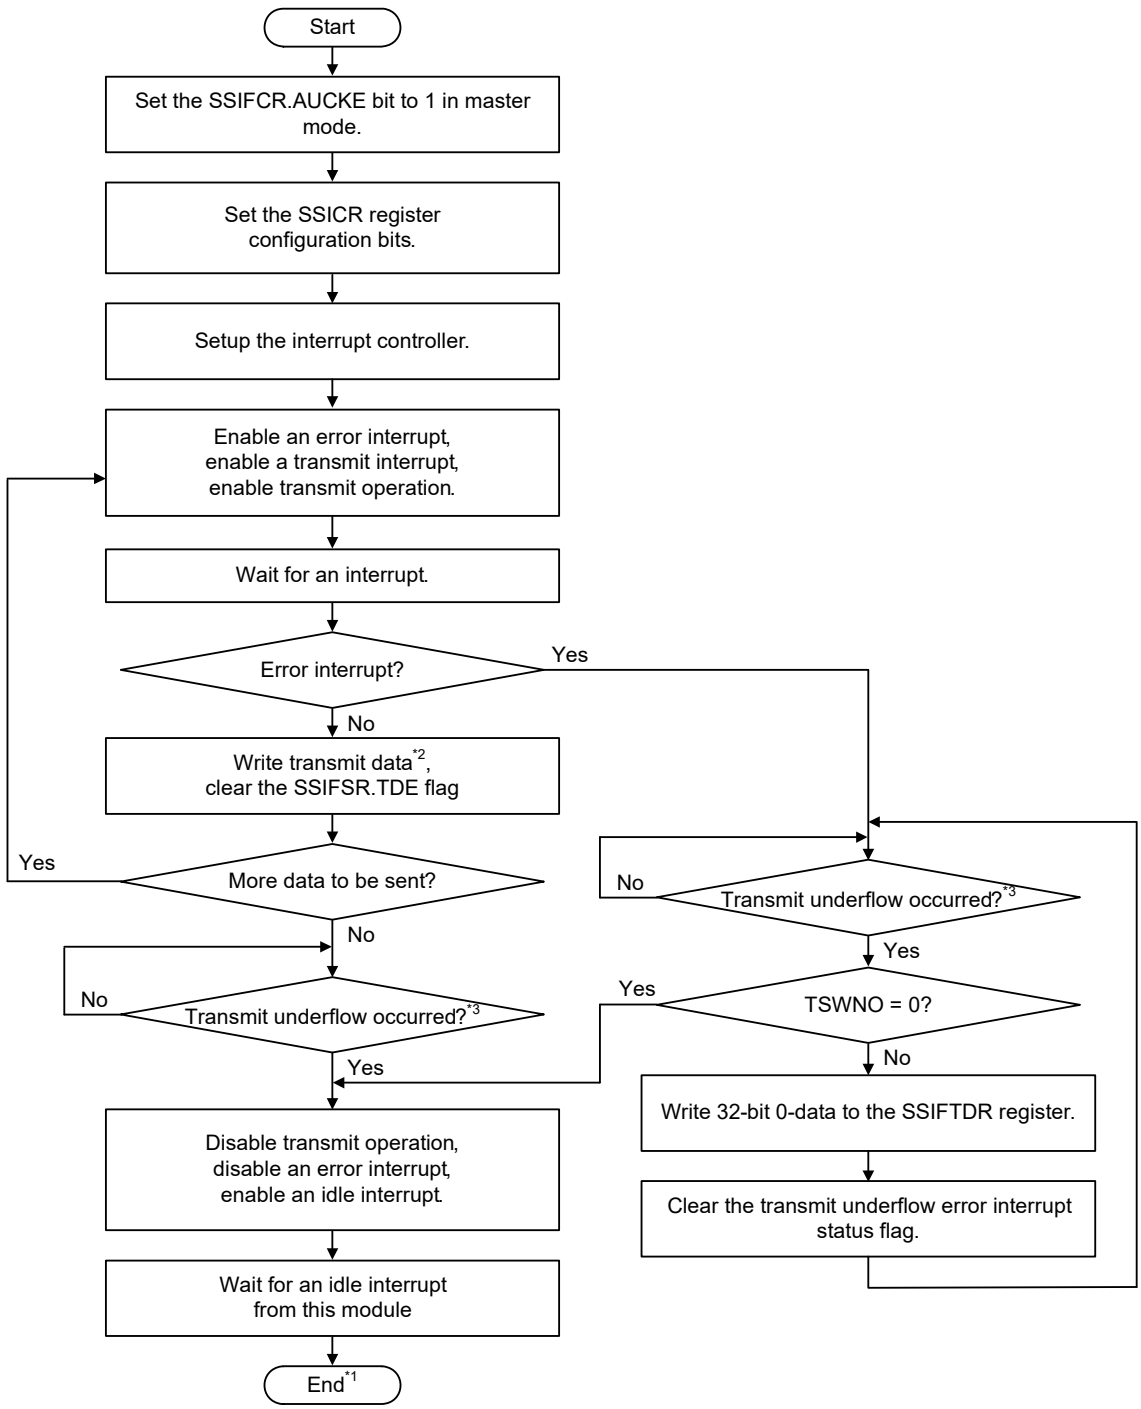
39.3.5 Transmit Operation

Transmission can be controlled by an interrupt that the SSI generates to supply data. In transmission using interrupts, write transmit data in 64-bit units regardless of the data format. If transmit data ends on a 32-bit boundary, write 32-bit 0-data (0000 0000h) after the last transmit data is written, and complete writing on a 64-bit boundary.
When stopping transmission, stop writing to the SSIFTDR register while 64-bit writing is completed. After writing is stopped, wait until a transmit underflow occurs before setting the TEN bit to 0. During transmit underflow, the last data input to SSIFTDR is continuously transmitted until this module enters the idle state. After the TEN bit is set to 0, the clock*1 should continue to be supplied until the SSISR.IIRQ flag indicates that the module is in the idle state. If a transmit underflow error or transmit overflow error occurs during data transmission, transmit data to SSIFTDR may not be written in a 64-bit units. In that case, stop writing data, wait until a transmit underflow error occurs, and check the TSWNO when the transmit underflow has occurred. When the TSWNO bit is 1, write 32-bit 0-data (0000 0000h) to SSIFTDR and wait until an underrun occurs again. Once the TSWNO bit is confirmed to be 0, after the TEN bit is set to 0, the clock*1 continue to be supplied until the SSISR.IIRQ flag indicates that the module is in the idle state.

Figure 39.18 shows transmission using interrupts.

Note 1. Input clock from the SSISCK pin when SSICR.SCKD bit = 0.
Master clock when SSICR.SCKD bit = 1.

(1) Transmission Using Interrupts



Note 1. If an error interrupt (underflow/overflow) occurs, go back to the start in the flowchart again.
Note 2. Write transmit data in 64-bit units regardless of the data word setting.
Note 3. Stop writing transmit data to the SSIFTDR register and wait until a transmit underflow occurs. During transmit underflow, the last data input to SSIFTDR is continuously transmitted until the module is in the idle state.

Figure 39.18 Transmission Using Interrupts

39.3.6 Receive Operation

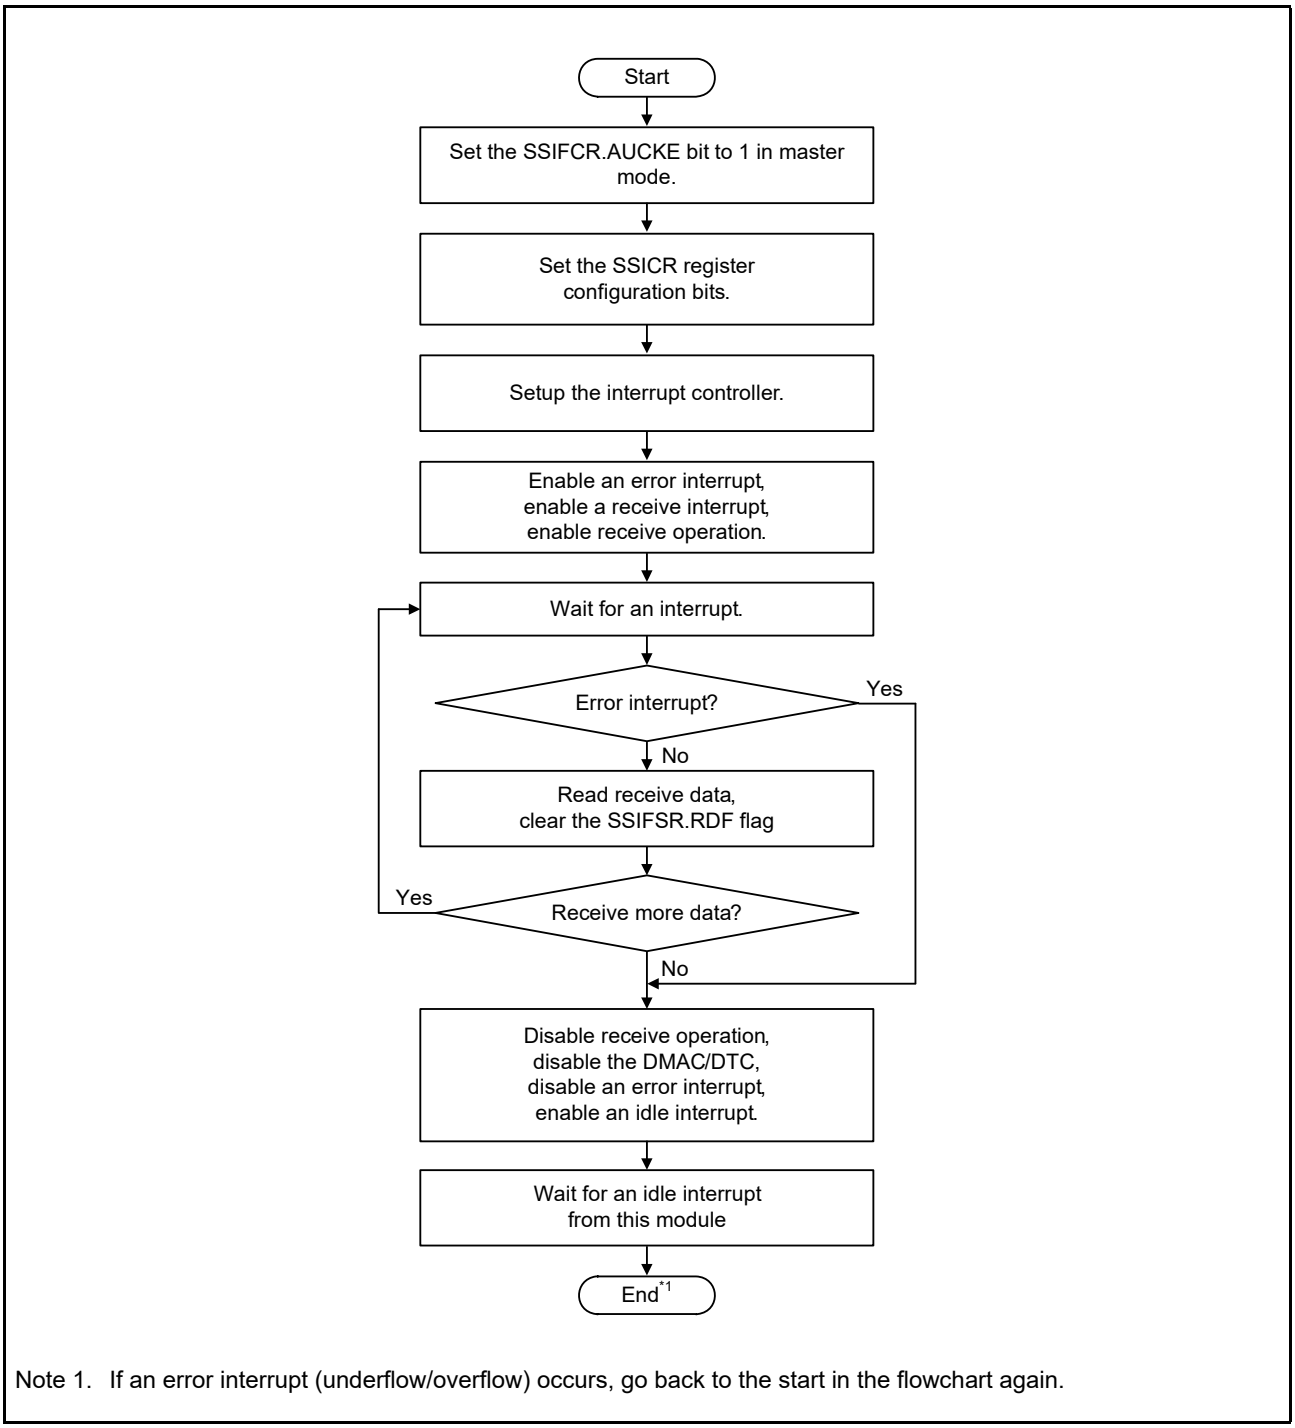
Like transmission, reception can be controlled by interrupt.

Figure 39.19 shows the flow of operation.

When disabling this module, the clock*1 continue to be supplied to this module until the SSISR.IIRQ bit indicates that the module is in the idle state.

Note 1. Input clock from the SSISCK pin when SSICR.SCKD bit = 0.
Master clock when SSICR.SCKD bit = 1.

(1) Reception Using Interrupt-Driven Data Flow Control



Note 1. If an error interrupt (underflow/overflow) occurs, go back to the start in the flowchart again.

Figure 39.19 Reception Using Interrupts

39.3.7 Serial Bit Clock Control

The SSI controls and selects the clock to be used for the serial bus interface, according to the SCKD and CKDV bit setting.
If the serial bit clock direction is set to input (SSICR.SCKD bit = 0), this module is in clock slave mode and the shift register uses the bit clock that was input to the SSISCK pin.

If the serial bit clock direction is set to output (SSICR.SCKD bit = 1), this module is in clock master mode, and the shift register uses the master clock or a divided master clock as the bit clock. The master clock is divided by the ratio specified by the SSICR.CKDV[3:0] bits for use as the bit clock by the shift register.
In either case the module pin, SSISCK, is the same as the bit clock.

39.4 Interrupt Sources

Table 39.6 lists the interrupt sources of the SSI. Each interrupt source can be enabled or disabled by the SSICR.TUIEN, TOIEN, RUIEN, ROIEN and IIEN bits, and the SSIFCR.TIE and RIE bits.

Table 39.6 SSI Interrupt Sources

Interrupt Source	Description	Interrupt Flag
SSIF	Transmit underflow interrupt, Transmit overflow interrupt, Receive underflow interrupt, Receive overflow interrupt, Idle interrupt	SSISR.TUIRQ SSISR.TOIRQ SSISR.RUIRQ SSISR.ROIRQ SSISR.IIRQ
SSIRXI	Receive data full interrupt	SSIFSR.RDF
SSITXI	Transmit data empty interrupt	SSIFSR.TDE

39.5 Usage Notes

39.5.1 Setting the Module Stop Function

Module stop state can be entered or released using the MSTPCRD register. The initial setting is for operation of the SSI to be stopped. SSI register access is enabled by releasing the module stop state.
For details on the MSTPCRD register, refer to section 9, Low-Power Consumption Function.

39.5.2 Notes on Changing Transfer Modes

For mode transitions between the transmitter, receiver, and transceiver while WS continue mode is disabled (SSITDMR.CONT = 0), set the SSICR.TEN and SSICR.REN bits to 0 and make a transition to the idle state once. Set the SSICR.TEN and SSICR.REN bits again while the module is in the idle state and restart transfer.

39.5.3 Limits on WS Continue Mode

If WS continue mode setting is changed, the operation of the SSISCK and SSIWS signals immediately after switching are not guaranteed. If it affects the device to be connected, do not change the setting dynamically.

40. Boundary Scan

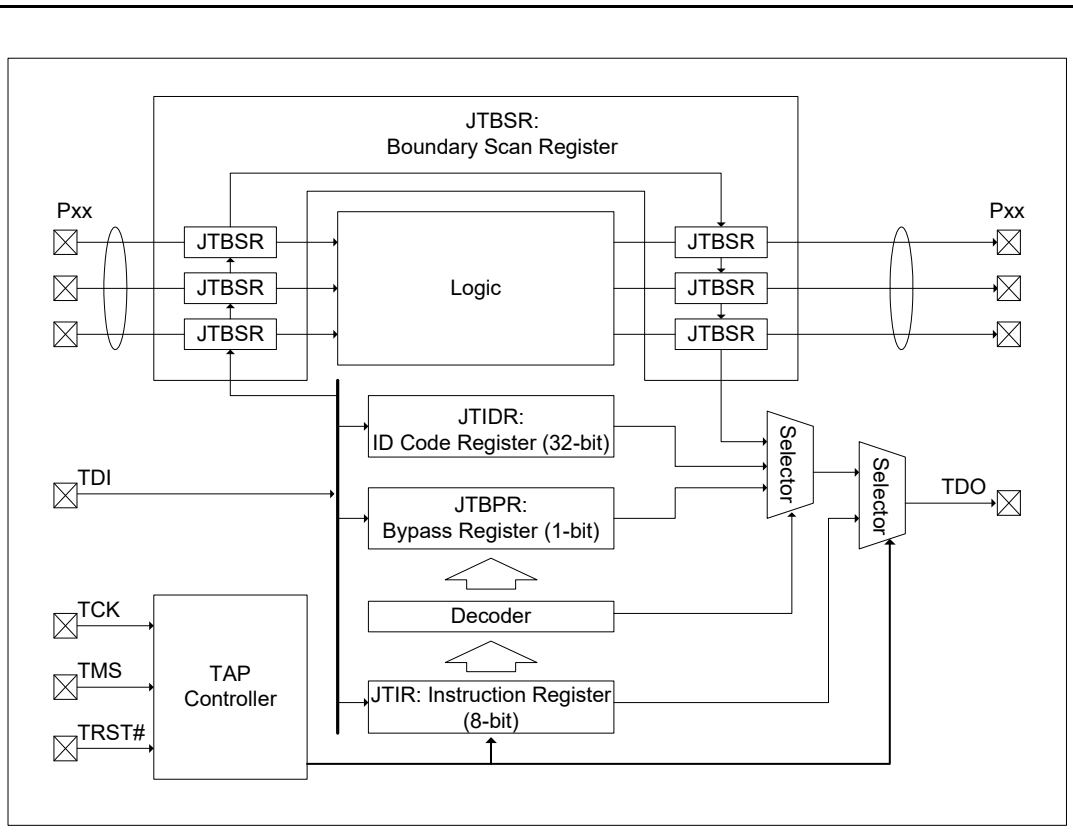
This LSI has the boundary scan function.
The boundary scan is a serial I/O interface based on the JTAG (Joint Test Action Group, IEEE Std.1149.1 and IEEE Standard Test Access Port and Boundary-Scan Architecture).

40.1 Overview

Table 40.1 lists the specifications of boundary scan.
Figure 40.1 shows a block diagram of the boundary scan function.

Table 40.1 Specifications of Boundary Scan

Item	Specifications
Boundary scan enabled/disabled	Boundary scan is enabled when the BSCANP pin is driven high.
Dedicated boundary scan pins	The TDO, TCK, TDI, TMS, and TRST# pins are dedicated for the JTAG when the boundary scan function is enabled.
Six test modes	BYPASS mode EXTEST mode SAMPLE/PRELOAD mode CLAMP mode HIGHZ mode IDCODE mode



JTBPR: Bypass register
JTBSR: Boundary scan register
JTIR: Instruction register
JTDIR: ID code register

Figure 40.1 JTAG Block Diagram

Table 40.2 shows the I/O pins used in the boundary scan function.

Table 40.2 Pin Configuration of JTAG

Pin Name	I/O	Description
TCK	Input	Test clock input pin Clock signal for boundary scan. Input the clock the duty cycle of which is 50% when boundary scan function is used.
TMS	Input	Test mode select pin
TDI	Input	Test data input pin
TDO	Output	Test data output pin
TRST#	Input	Test reset input pin

40.2 Register Descriptions

Instructions can be input to the instruction register via the TDI pin by serial transfer.
The bypass register, which is a 1-bit register, is connected between the TDI and TDO pins in BYPASS mode.
The boundary scan register, which is configured according to Table 40.5, is connected between the TDI and TDO pins when test data are being shifted in.
None of the registers is accessible from the CPU. Table 40.3 shows the availability of serial transfer for the registers.

Table 40.3 Serial Transfer for the Registers

Register	Serial Input	Serial Output
Instruction register	Available	Available
ID code register	Available	Available
Bypass register	Available	Available
Boundary scan register	Available	Available

Note: Any serial transfer is available if standards for the boundary scan function are satisfied.

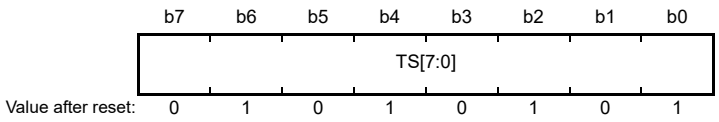
40.2.1 Instruction Register (JTIR)

The JTIR register is an 8-bit register.

Boundary scan instructions can be transferred to the instruction register by serial input from the TDI pin.

The instruction register is initialized when the TRST# pin is driven to the low level, or when the TAP controller is in the Test-Logic-Reset state.

Address(es): —



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	TS[7:0]	Test Bit Set	The command configuration is as shown in Table 40.4.	—

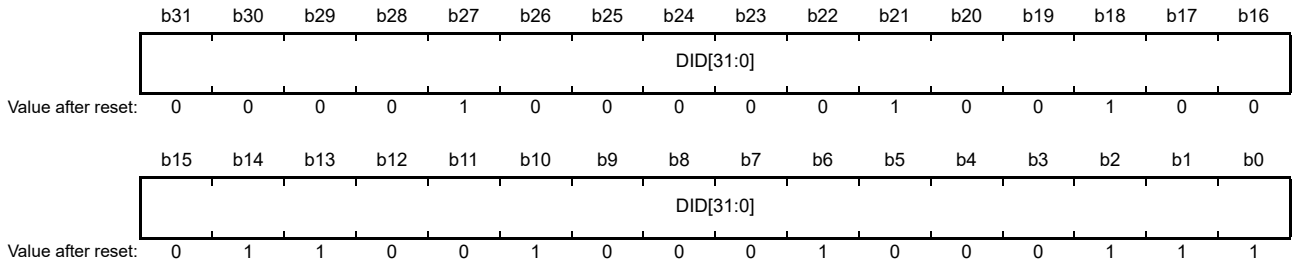
Table 40.4 Command Configuration

TS7	TS6	TS5	TS4	TS3	TS2	TS1	TS0	Instruction
0	0	0	0	0	0	0	0	EXTEST
0	1	0	0	0	0	0	0	SAMPLE/PRELOAD
0	1	0	1	0	1	0	1	IDCODE (value after reset)
1	1	0	1	0	0	0	0	CLAMP
1	0	0	0	0	0	0	0	HIGHZ
1	1	1	1	1	1	1	1	BYPASS
Other than above								Reserved

40.2.2 ID Code Register (JTIDR)

The JTIDR register is a 32-bit register.
ID code register data is output from the TDO pin when the IDCODE instruction is executed.

Address(es): —



Bit	Symbol	Bit Name	Description	R/W
b31-b0	DID[31:0]	Reserved	This register has the fixed value that indicates the device IDCODE.	—

40.2.3 Bypass Register (JTBPR)

The JTBPR register is a 1-bit register.
This register is connected between the TDI and TDO pins when BYPASS mode is set.
The JTBPR register cannot be read from or written to by the CPU.

40.2.4 Boundary Scan Register (JTBSR)

The JTBSR register is a shift register which is located in the pad to control the external input and output pins of this LSI chip.
The EXTEST, SAMPLE/PRELOAD, CLAMP, and HIGHZ commands can be used to perform boundary-scan testing.
Table 40.5 shows the correspondence between the pins of this LSI chip and the bits of the boundary scan register.
The value is undefined after a reset.

40.3 Operation

The boundary scan function is valid when the RES# and BSCANP pins are driven high.

40.3.1 TAP Controller

Figure 40.2 shows the state transition diagram of the TAP controller. Table 40.7 describes each state.

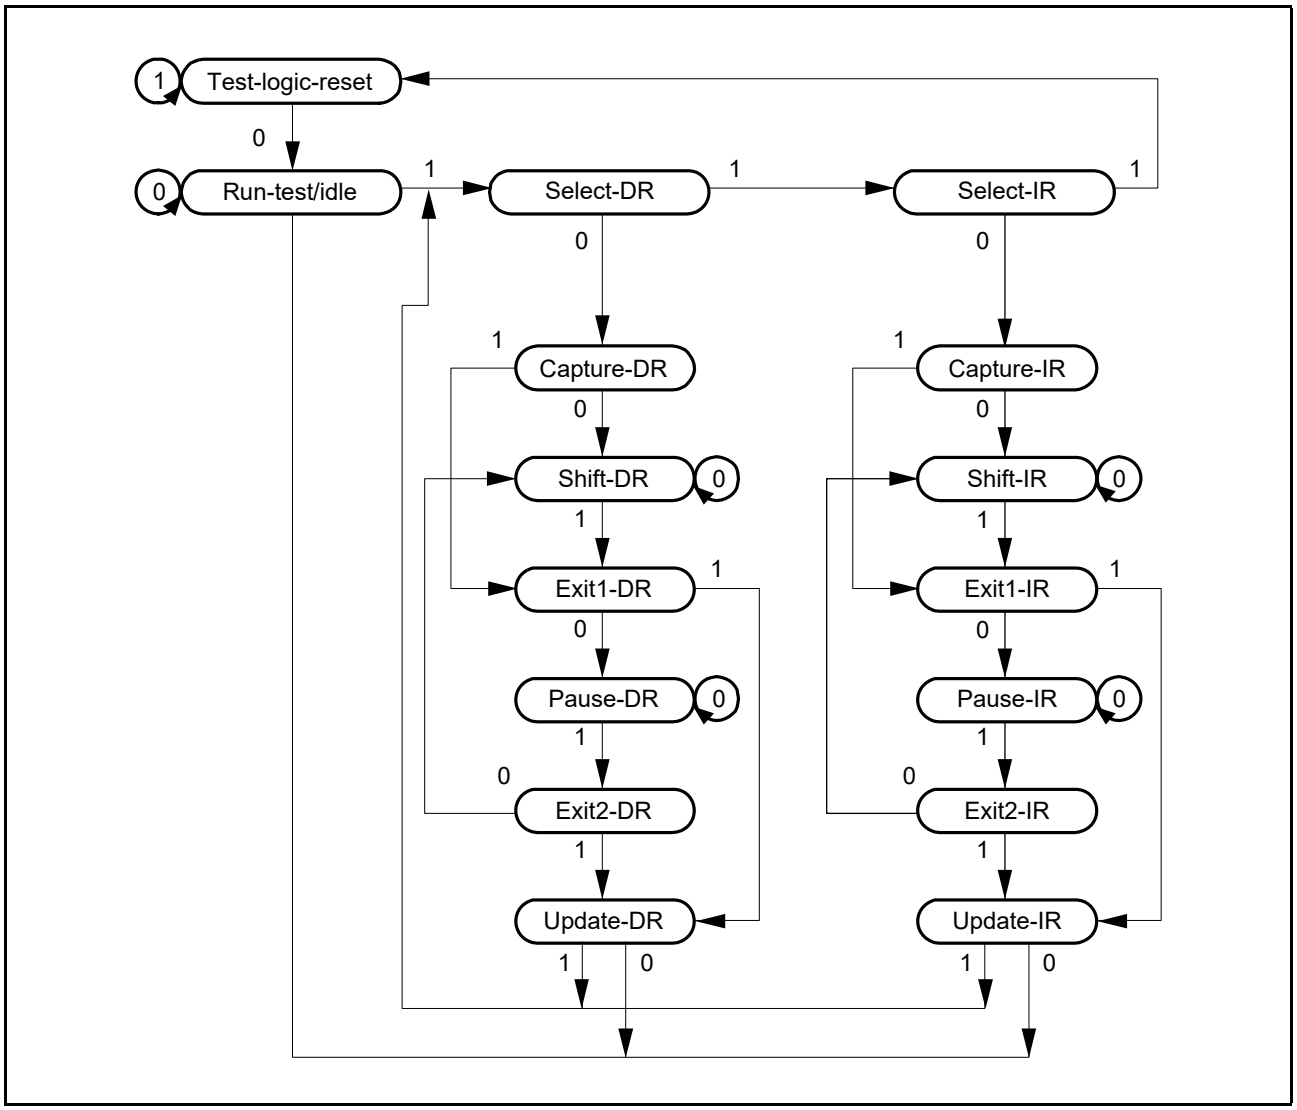

Figure 40.2 State Transition Diagram of TAP Controller

Table 40.7 Explanation of States

State	Explanation
Test Logic Reset	Reset state of the TAP controller. The LSI is in this state during normal operation.
Run Test/Idle	Test execution state
Select DR Scan	Temporary state used for selecting a data register.
Select IR Scan	Temporary state used for selecting an instruction register.
Capture DR	Data of the test data register corresponding to the current instruction is captured in parallel.
Shift DR	The test data register corresponding to the current instruction is connected between the TDI and TDO pins, and data is transferred serially.
Exit DR	Temporary state
Pause DR	Clocks are applied while the value input in the Shift DR state is retained.
Exit2 DR	Temporary state
Update DR	Output latches of the test data register corresponding to the current instruction are updated.
Capture IR	A fixed value is input to the instruction register.
Shift IR	The instruction register is connected between the TDI and TDO pins, and data is transferred serially.
Exit IR	Temporary state
Pause IR	Clocks are applied while the value input in the Shift IR state is retained.
Exit2 IR	Temporary state
Update IR	The current instruction is updated to the instruction input in the Shift IR state.

40.3.2 List of Commands

(1) BYPASS [Instruction Code: 1111 1111b]

The BYPASS instruction drives the bypass register. This instruction shortens the shift path, facilitating the transfer of serial data to other LSIs on a printed-circuit board at higher speeds. While this instruction is being executed, the test circuit does not affect the system circuit.
The bypass register is connected between the TDI and TDO pins. Bypass operation is initiated from shift-DR operation. The TDO is set to 0 in the first clock cycle in the Shift-DR state. In the subsequent clock cycles, the TDI signal is output on the TDO pin.

(2) EXTEST [Instruction Code: 0000 0000b]

The EXTEST instruction is used to test external circuits when this LSI is installed on the printed circuit board. If this instruction is executed, output pins are used to output test data (specified by the SAMPLE/PRELOAD instruction) from the boundary scan register to the print circuit board, and input pins are used to input test result to the boundary scan register from the print circuit board.

(3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]

The SAMPLE/PRELOAD instruction is used to input data from this LSI's internal circuits to the boundary scan register, output data from the scan path, and reload the data to the scan path. While this instruction is executed, input signals are directly input to this LSI and output signals are also directly output to the external circuits. The system circuit of this LSI is not affected by this instruction.
In SAMPLE operation, the boundary scan register latches the snap shot of data transferred from input pins to internal circuit or data transferred from internal circuit to output pins. The latched data is read from the scan path. The scan register latches the snap shot at the rising edge of the TCK in Capture-DR state. The scan register latches snap shots without affecting the LSI normal operation.
In PRELOAD operation, the value after reset is written from the scan path to the parallel output latch of the boundary scan register prior to the EXTEST instruction execution. If the EXTEST instruction is executed without executing this PRELOAD operation, undefined values are output over the period until the first scan sequence is completed (transfer to the output latch). (In the EXTEST instruction, output parallel latches are always output to the output pins.)

(4) IDCODE [Instruction Code: 0101 0101b]

When the IDCODE instruction is selected, the ID code register value is output from the TDO in LSB-first order in Shift-DR state of the TAP controller. While this instruction is being executed, the test circuit does not affect the system circuit. The instruction register is initialized by the IDCODE instruction in Test-Logic-Reset state of the TAP controller.

(5) CLAMP [Instruction Code: 1101 0000b]

When the CLAMP instruction is selected, output pins output the boundary scan register value which was specified by the SAMPLE/PRELOAD instruction in advance. While the CLAMP instruction is selected, the status of the boundary scan register is maintained regardless of the TAP controller state.
The bypass register is connected between the TDI and TDO pins, leading to the same operation as when BYPASS mode has been selected

(6) HIGHZ [Instruction Code: 1000 0000b]

When the HIGHZ instruction is selected, all output pins enter high-impedance state. While the HIGHZ instruction is selected, the status of the boundary scan register is maintained regardless of the TAP controller state. The bypass register is connected between the TDI and TDO pins, leading to the same operation as when the BYPASS instruction has been selected.

40.4 Usage Notes

1. For serial transfer, data are input or output in LSB-first order. See Figure 40.3.

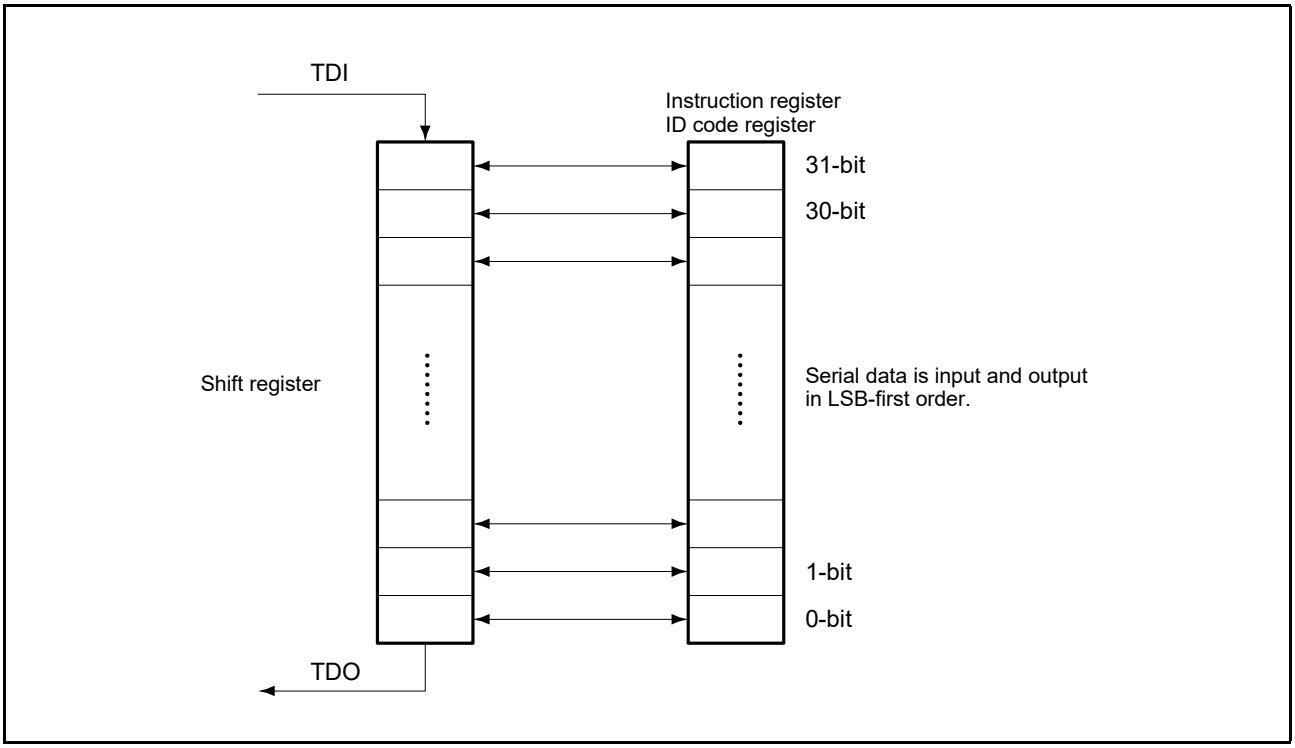

Figure 40.3 Serial Data Input/Output

2. Pins of the boundary scan (TDI, TMS, and TRST#) have to be pulled up by pull-up resistors. However, if an on-chip emulator is in use, handle the #TRST pin according to the manual for the given on-chip emulator.
3. Power supply pins (VDD, VSS, VCCQ33, PLLVDD0, PLLVSS0, PLLVDD1, PLLVSS1, VDD33_USB, VSS_USB, DVDD_USB, AVCC0, AVSS0, AVCC1, and AVSS1) cannot be boundary-scanned.
4. Analog reference pins (VREFH0, VREFL0, VREFH1, VREFL1, and USB_RREF) cannot be boundary-scanned.
5. Clock pins (EXTAL and XTAL) cannot be boundary-scanned.
6. The clock input mode select pin (OSCTH) cannot be boundary-scanned.
7. The reset pin (RES#) cannot be boundary-scanned.
8. The operating mode select input pins (MD0 to MD2) cannot be boundary-scanned.
9. USB dedicated pins (USB_DP and USB_DM) cannot be boundary-scanned.
10. The boundary-scan pin (BSCANP) cannot be boundary-scanned.
11. The boundary-scan pins (TCK, TMS, TRST#, TDI, and TDO) cannot be boundary-scanned.
12. Output registers of the I/O port C pins (PC0 to PC7) and pin P30 cannot be boundary-scanned.
13. The boundary scan function is not available when the chip is in the reset state.
14. For a pin that incorporates open-drain functionality and for which the open-drain function is enabled, if the boundary-scan function sets the corresponding bit in the output scan register and output enable register to 1, executing an EXTEST, CLAMP, or SAMPLE/PRELOAD instruction makes the pin output the high level rather than placing it in the high-impedance state.
15. Be sure to satisfy the standards for the boundary scan function when multiplex I/O is used. Figure 40.4, AD Pin Configuration shows the configuration of the multiplex I/O (P90 to P97, PD0 to PD7, and P86 and P87) in combination with the AD input. When the boundary scan function is used with the pins to be used as AD input pins, the conflict with the AD input or sneak current might be generated.
16. Analog input pins (AN000, AN001, AN002, AN003, AN004, AN005, AN006, and AN007) cannot be boundary-scanned.

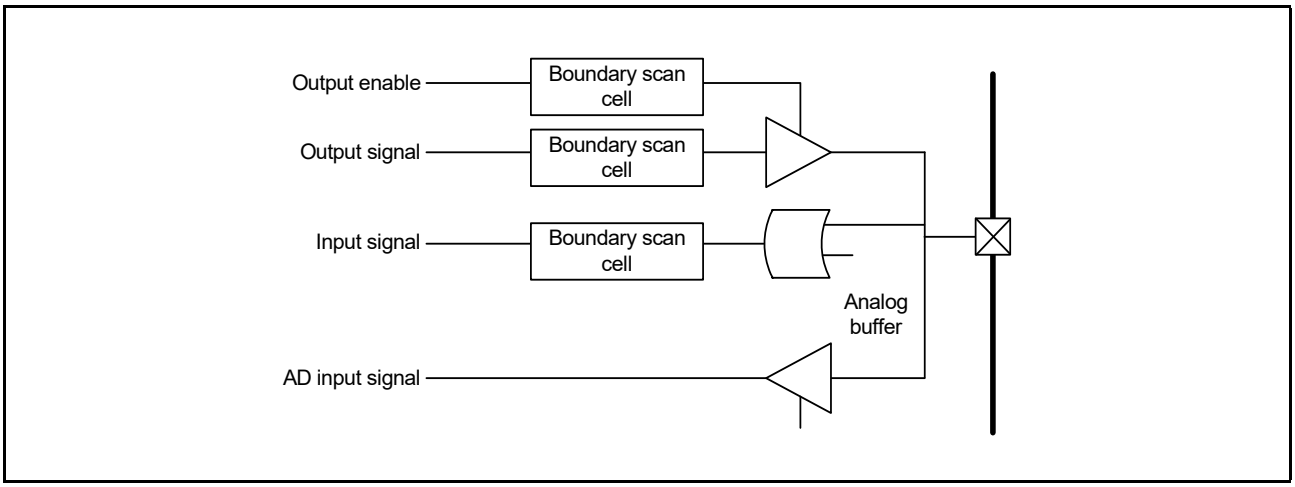

Figure 40.4 AD Pin Configuration

41. ΔΣ Interface (DSMIF)

This LSI has a total of four ΔΣ interfaces (DSMIFs), consisting of three interfaces (U, V, and W) in unit 0 and one interface (X) in unit 1. The DSMIF can be connected with up to four external ΔΣ modulators. It is capable of filtering delta-sigma modulated 1-bit digital input data and converting it into 16-bit digital data.

41.1 Overview

Table 41.1 lists the specifications of the DSMIF. Figure 41.1 is a block diagram of the DSMIF.

Table 41.1 DSMIF Specifications

Item	Description
Number of channels	Unit 0: channel 0 (U), channel 1 (V), and channel 2 (W) Unit 1: channel 3 (X)
Functions	• Capable of filtering 1-bit digital input data MDATAm (m = 0 to 2, 3) and converting them into 16-bit digital values. • The SINC filters are selectable as one-, two-, or three-stage. • MCLKm (m = 0 to 2, 3) can be output at up to 25 MHz in master operation (DSCLK0, DSCLK1) and input at up to 25 MHz in slave operation. • Crests and troughs can trigger capture, allowing capture of values for current with the same timing (only for channels 0 to 2 or channel 3).
Error source output	Error signals for the following reasons are output to the error control module (ECM). • Abnormal overcurrent detection (in units 0 and 1) • Short-circuit detection (in units 0 and 1) • Abnormal total current detection (in unit 0)
Low-power consumption function	The module-stop state can be set.

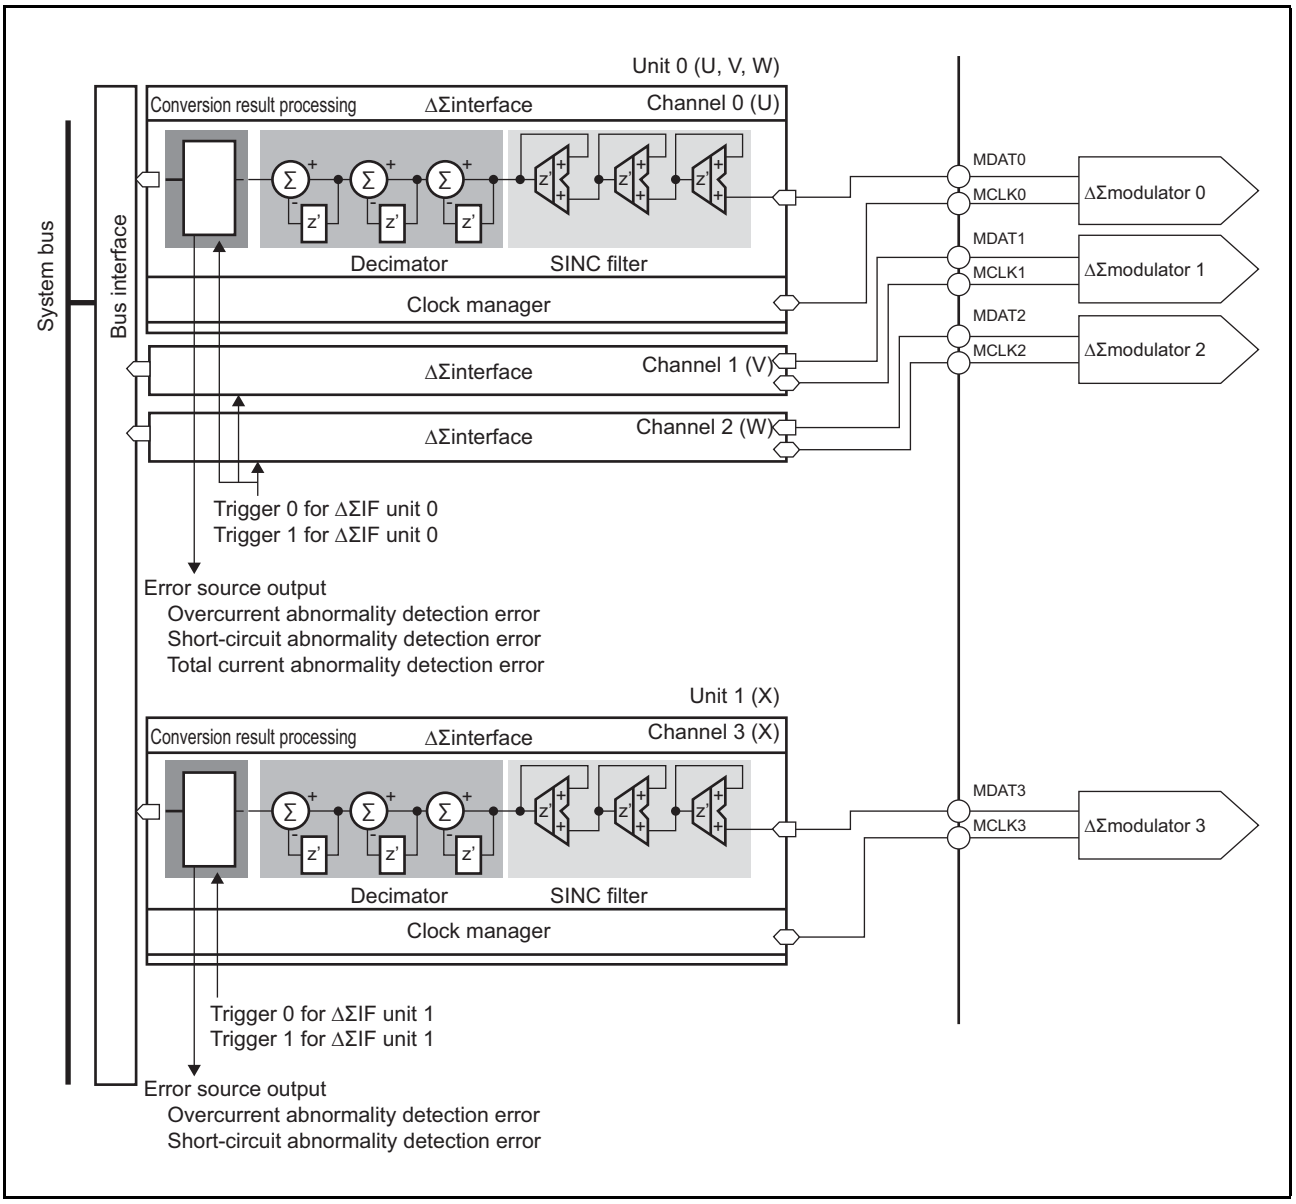

Figure 41.1 DSMIF Block Diagram

Table 41.2 lists the input/output pins of the DSMIF.

Table 41.2 Pin Configuration of DSMIF

Channel	Pin Name	I/O	Description
DSMIF0 (U)	MCLK0	I/O	Clock input/output pin
	MDAT0	Input	Data input pin
DSMIF1 (V)	MCLK1	I/O	Clock input/output pin
	MDAT1	Input	Data input pin
DSMIF2 (W)	MCLK2	I/O	Clock input/output pin
	MDAT2	Input	Data input pin
DSMIF3 (X)	MCLK3	I/O	Clock input/output pin
	MDAT3	Input	Data input pin

41.2 Register Descriptions

41.2.1 UVW Control Register (UVWCTL)

The UVWCTL register controls the settings for unit 0 (U, V, and W) of the DSMIF.
Writing to bits 1 to 31 during operations (i.e., while the UVWCTL.ENABLE bit = 1) is prohibited.

Address(es): DSMIF.UVWCTL A007 2000h

Bit	Symbol	Bit Name	Description	R/W
b0	ERUI	Channel 0 (U) Overcurrent Abnormality Detection Status	This bit indicates the detection of an overcurrent abnormality on channel 0 (U). 0: Overcurrent abnormality has not been found. 1: Overcurrent abnormality has been found. Setting condition: Overcurrent abnormality being detected from the values of data on current in the U2DATA register. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b1	ERVI	Channel 1 (V) Overcurrent Abnormality Detection Status	This bit indicates the detection of an overcurrent abnormality on channel 1 (V). 0: Overcurrent abnormality has not been found. 1: Overcurrent abnormality has been found. Setting condition: Overcurrent abnormality being detected from the values of data on current in the V2DATA register. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b2	ERWI	Channel 2 (W) Overcurrent Abnormality Detection Status	This bit indicates the detection of an overcurrent abnormality on channel 2 (W). 0: Overcurrent abnormality has not been found. 1: Overcurrent abnormality has been found. Setting condition: Overcurrent abnormality being detected from the values of data on current in the W2DATA register. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ERUSC	Channel 0 (U) Short-Circuit Abnormality Detection Status	This bit indicates the detection of a short-circuit abnormality on channel 0 (U). 0: Short-circuit abnormality has not been found. 1: Short-circuit abnormality has been found. Setting condition: Short-circuit abnormality being detected from 1-bit digital input data MDATA0. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b5	ERVSC	Channel 1 (V) Short-Circuit Abnormality Detection Status	This bit indicates the detection of a short-circuit abnormality on channel 1 (V). 0: Short-circuit abnormality has not been found. 1: Short-circuit abnormality has been found. Setting condition: Short-circuit abnormality being detected from 1-bit digital input data MDATA1. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W

Bit	Symbol	Bit Name	Description	R/W
b6	ERWSC	Channel 2 (W) Short-Circuit Abnormality Detection Status	This bit indicates the detection of a short-circuit abnormality on channel 2 (W). 0: Short-circuit abnormality has not been found. 1: Short-circuit abnormality has been found. Setting condition: Short-circuit abnormality being detected from 1-bit digital input data MDATA2. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	ERUVWIGND	Unit 0 (U, V, W) Total Current Abnormality Detection Status	This bit indicates the detection of total current abnormalities in unit 0 (U, V, and W). 0: Total current abnormality has not been found. 1: Total current abnormality has been found. Setting condition: Total current abnormality being detected from the sum of the data on current in the U1DATA, V1DATA, and W1DATA registers. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

41.2.3 UVW Overcurrent Abnormality Detection Lower Limit Setting Register (UVWIUNCMP)

The UVWIUNCMP register is used to set the lower limit for judging the detection of overcurrent abnormalities in unit 0 (U, V, or W).

If a value for current in the U2DATA, V2DATA, or W2DATA register falls below the value set in this register, the UVW overcurrent abnormality detection error signal is output.

Address(es): DSMIF.UVWIUNCMP A007 2008h

b15 to b0	CMPUVWIUNDER[15:0]	UVW Overcurrent Abnormality Detection Lower Limit Setting	When y2DATA < CMPUVWIUNDER[15:0], the corresponding UVWSTA.ERyI bit (y = U, V, or W) is set to 1. Also, the UVW overcurrent abnormality detection error signal is output to the error control module (ECM) regardless of the setting of the UVWSTA.ERyI bit.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

41.2.4 UVW Overcurrent Abnormality Detection Upper Limit Setting Register (UVWIOVCMP)

The UVWIOVCMP register is used to set the upper limit for judging the detection of overcurrent abnormalities in unit 0 (U, V, or W).

If a value for current in the U2DATA, V2DATA, or W2DATA register exceeds the value set in this register, the UVW overcurrent abnormality detection error signal is output.

Address(es): DSMIF.UVWIOVCMP A007 200Ch

b15 to b0	V1VDATA [15:0]	Channel 1 (V) Current Value Capture (Trough Trigger)	Value for current obtained by capturing V1DATA in response to trigger 1 for ΔΣ IF unit 0 (the trough trigger from a PWM timer)	R
b31 to b16	—	Reserved	These bits are read as 0.	R

41.2.16 Channel V Current Value Register 2 (V2DATA)

The V2DATA register indicates the value for current in channel 1 (V) of unit 0 (U, V, and W).
This register holds the 16-bit digital values produced by filtering 1-bit digital input data MDATA1 according to the settings of the UVWCTL.SINC2SEL, UVWCTL.WORD2GEN, and UVWCTL.BITSHIFT2 bits.
The value for current is used in the judgment of overcurrent abnormalities in accord with the settings in the UVWIUNCMP and UVWIOVCMP registers.

Address(es): DSMIF.V2DATA A007 203Ch

b31 to b16	—	Reserved	These bits are read as 0.	R

41.2.18 Channel W Current Value Crest Trigger Capture Register 1 (W1CDATA)

The W1CDATA register indicates the result of capturing the value held in the W1DATA register in response to trigger 0 for ΔΣ IF unit 0.

The value for current in the W1DATA register can be captured in response to a crest trigger by using the event link controller (ELC) to set the crest trigger of the timers set to PWM mode (MTU3a, GPTa) as trigger 0 for ΔΣ IF unit 0. For details, see section 41.3.3.1, Conversion of Values for Current and Capture of Values in Response to Crest and Trough Triggers.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ENABLE	Operation Enable	This bit enables operation of ΔΣ interfaces (unit 1 (X)). 0: Filtering is stopped. 1: Filtering is started.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	SINC1SEL [1:0]	Current Value Storage SINC Filter Select	These bits set the filters for the X1DATA register*1. 00: sinc3 (3-stage filter) 01: sinc1 (1-stage filter) 10: sinc2 (2-stage filter) Settings other than above are prohibited.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b14 to b12	WORD1GEN [2:0]	Current Value Storage Decimation Clock Select	These bits set the decimation clock for the X1DATA register*1. 000: MCLK3/4 010: MCLK3/8 011: MCLK3/16 100: MCLK3/32 101: MCLK3/64 110: MCLK3/128 111: MCLK3/256 Settings other than above are prohibited.	R/W
b15	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b19 to b16	BITSHIFT1 [3:0]	Current Value Storage Bit Shift Select	These bits set the bit shift for the X1DATA register (i.e., these bits select the 16 bits to be used from the 24-bit results of decimation)*1. 0000: [23:8] 0001: [20:5] 0010: [17:2] 0011: [15:0] 0100: [14:0], 1'b0 0101: [13:0], 2'b00 0110: [11:0], 4'b000 0111: [9:0], 6'b00_0000 1000: [8:0], 7'b000_0000 1001: [7:0], 8'b0000_0000 1010: [6:0], 9'b0_0000_0000 1011: [5:0], 10'b00_0000_0000 1100: [4:0], 11'b000_0000_0000 Settings other than above are prohibited. When BITSHIFT1[3:0] = 0100b to 1100b, the lower-order bits are padded with 0.	R/W

Bit	Symbol	Bit Name	Description	R/W
b21, b20	SINC2SEL [1:0]	Overcurrent Abnormality Detection SINC Filter Select	These bits set the filters for the X2DATA register*1. 00: sinc3 (3-stage filter) 01: sinc1 (1-stage filter) 10: sinc2 (2-stage filter) Settings other than above are prohibited.	R/W
b23, b22	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b26 to b24	WORD2GEN [2:0]	Overcurrent Abnormality Detection Decimation Clock Select	These bits set the decimation clock for the X2DATA registers*1. 000: MCLK3/4 010: MCLK3/8 011: MCLK3/16 100: MCLK3/32 101: MCLK3/64 110: MCLK3/128 111: MCLK3/256 Settings other than above are prohibited.	R/W
b27	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b31 to b28	BITSHIFT2 [3:0]	Overcurrent Abnormality Detection Bit Shift Select	These bits set the bit shift for the X2DATA register (i.e., these bits select the 16 bits to be used from the 24-bit results of decimation)*1. 0000: [23:8] 0001: [20:5] 0010: [17:2] 0011: [15:0] 0100: [14:0], 1'b0 0101: [13:0], 2'b00 0110: [11:0], 4'b000 0111: [9:0], 6'b00_0000 1000: [8:0], 7'b000_0000 1001: [7:0], 8'b0000_0000 1010: [6:0], 9'b0_0000_0000 1011: [5:0], 10'b00_0000_0000 1100: [4:0], 11'b000_0000_0000 Settings other than above are prohibited. When BITSHIFT2[3:0] = 0100b to 1100b, the lower-order bits are padded with 0.	R/W

Note 1. For the relationship between the filter setting by the corresponding bits and values for current, see section 41.3.5, Settings for Filtering.

41.2.22 XYZ Status Register (XYZSTA)

The XYZSTA register indicates the state of error detection in unit 1 (X).

Address(es): DSMIF.XYZSTA A007 2084h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Value after reset:	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	The read value is undefined. The write value should be 0.	R/W
b4	ERXSC	Channel 3 (X) Short-Circuit Abnormality Detection Status	This bit indicates the detection of a short-circuit abnormality on channel 3 (X). 0: Short-circuit abnormality has not been found. 1: Short-circuit abnormality has been found. Setting condition: Short-circuit abnormality being detected from MDATA3. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b6, b5	—	Reserved	These bits are read as 1. The write value should be 1. However, reading this bit after writing 1 to it returns 0.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b8	ERXI	Channel 3 (X) Overcurrent Abnormality Detection Status	This bit indicates the detection of an overcurrent abnormality on channel 3 (X). 0: Overcurrent abnormality has not been found. 1: Overcurrent abnormality has been found. Setting condition: Overcurrent abnormality being detected from the values of data on current in the X2DATA register. Clearing condition: Writing 1 to this bit after it has been set to 1.	R/W
b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

41.2.23 XYZ Overcurrent Abnormality Detection Lower Limit Setting Register (XYZIUNCMP)

The XYZIUNCMP register is used to set the lower limit for judging the detection of overcurrent abnormalities in unit 1 (X).

If a value for current in the X2DATA register falls below the value set in this register, the X overcurrent abnormality detection error signal is output.

Address(es): DSMIF.XYZIUNCMP A007 2098h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	CMPXIUNDER[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPXIUNDER[15:0]	X Overcurrent Abnormality Detection Lower Limit Setting	When X2DATA < CMPXIUNDER[15:0], the corresponding XYZSTA.ERXI bit is set to 1. Also, the X overcurrent abnormality detection error signal is output to the error control module (ECM) regardless of the setting of the XYZSTA.ERXI bit.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

41.2.24 XYZ Overcurrent Abnormality Detection Upper Limit Setting Register (XYZIOVCMP)

The XYZIOVCMP register is used to set the upper limit for judging the detection of overcurrent abnormalities in unit 1 (X).

If a value for current in the X2DATA register exceeds the value set in this register, the X overcurrent abnormality detection error signal is output.

Address(es): DSMIF.XYZIOVCMP A007 209Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPXIOVER[15:0]	X Overcurrent Abnormality Detection Upper Limit Setting	When X2DATA > CMPXIOVER[15:0], the corresponding XYZSTA.ERXI bit is set to 1. Also, the X overcurrent abnormality detection error signal is output to the error control module (ECM) regardless of the setting of the XYZSTA.ERXI bit.	R/W
b31 to b16	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

41.2.25 XYZ Short-Circuit Abnormality Detection 0 Data Input Threshold Setting Register (XYZSCUNCMP)

The XYZSCUNCMP register is used to set the threshold for the input of “0”-valued data for judging the detection of short-circuit abnormalities in unit 1 (X).

The number of times 0 is consecutively input as 1-bit digital input data MDATA3 is counted and the X short-circuit abnormality detection error signal is output if the number of times exceeds the value in this register.

Address(es): DSMIF.XYZSCUNCMP A007 2090h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b12 to b0	CMPXSCOVER[12:0]	X Short-Circuit Abnormality Detection Lower Limit Setting	When the number of times 1 is consecutively input as MDATA3 is greater than CMPXSCOVER[12:0], the XYZSTA.ERXSC bit is set to 1. Also, the X short-circuit abnormality detection error signal is output to the error control module (ECM) regardless of the setting of the XYZSTA.ERXSC bit.	R/W
b31 to b13	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

41.2.27 Channel X Current Value Register 1 (X1DATA)

The X1DATA register indicates the value for current in channel 3 (X) of unit 1 (X).
This register holds the 16-bit digital values produced by filtering 1-bit digital input data MDATA3 according to the settings of the XYZCTL.SINC1SEL, XYZCTL.WORD1GEN, and XYZCTL.BITSHIFT1 bits.

Address(es): DSMIF.X1DATA A007 20A0h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

	X1DATA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	X1DATA [15:0]	Channel 3 (X) Current Value 1	16-bit value for current obtained by filtering MDATA3 according to the settings of the XYZCTL.SINC1SEL, XYZCTL.WORD1GEN, and XYZCTL.BITSHIFT1 bits	R
b31 to b16	—	Reserved	These bits are read as 0.	R

41.2.28 Channel X Current Value Crest Trigger Capture Register 1 (X1CDATA)

The X1CDATA register indicates the result of capturing the value held in the X1DATA register in response to trigger 0 for ΔΣ IF unit 1.

The value for current in the X1DATA register can be captured in response to a crest trigger by using the event link controller (ELC) to set the crest trigger of the timers set to PWM mode (MTU3a, GPTa) as trigger 0 for ΔΣ IF unit 1. For details, see section 41.3.3.1, Conversion of Values for Current and Capture of Values in Response to Crest and Trough Triggers.

b15 to b0	X1CDATA [15:0]	Channel 3 (X) Current Value Capture (Crest Trigger)	Value for current obtained by capturing X1DATA in response to trigger 0 for ΔΣ IF unit 1 (the crest trigger from a PWM timer)	R
b31 to b16	—	Reserved	These bits are read as 0.	R

41.2.29 Channel X Current Value Trough Trigger Capture Register 1 (X1VDATA)

The X1VDATA register indicates the result of capturing the value held in the X1DATA register in response to trigger 1 for ΔΣ IF unit 1.

The value for current in the X1DATA register can be captured in response to a trough trigger by using the event link controller (ELC) to set the trough trigger of the timers set to PWM mode (MTU3a, GPTa) as trigger 1 for ΔΣ IF unit 1. For details, see section 41.3.3.1, Conversion of Values for Current and Capture of Values in Response to Crest and Trough Triggers.

Address(es): DSMIF.X1VDATA A007 20A8h

41.2.30 Channel X Current Value Register 2 (X2DATA)

The X2DATA register indicates the value for current in channel 3 (X) of unit 1 (X).

This register holds the 16-bit digital values produced by filtering 1-bit digital input data MDATA3 according to the settings of the XYZCTL.SINC2SEL, XYZCTL.WORD2GEN, and XYZCTL.BITSHIFT2 bits.

The value for current is used in the judgment of overcurrent abnormalities in accord with the settings in the XYZIUNCMP and XYZIOVCMP registers.

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	X2DATA [15:0]	Channel 3 (X) Current Value 2	16-bit value for current obtained by filtering MDATA3 according to the settings of the UVWCTL.SINC2SEL and UVWCTL.WORD2GEN bits	R
b31 to b16	—	Reserved	These bits are read as 0.	R

41.3 Operation

The DSMIF consists of the SINC filter, decimator, and conversion result processing stages.
These stages filter 1-bit digital input data MDATAm (m = 0 to 2, 3) input to the DSMIF to produce 16-bit values for current per channel, and are also used in the detection of errors in the form of overcurrents, short-circuits, and abnormal total currents.
The decimator stage has two types of circuit: one for storage of values for current and one for detection of overcurrent abnormalities.
The conversion result processing stage handles the following four functions: conversion of values for current, capturing values in response to crest or trough triggers, overcurrent abnormality detection, short-circuit abnormality detection, and total current abnormality detection (only for channels 0 to 2).

41.3.1 SINC Filtering

Each DSMIF has three 24-bit adder stages to make up the SINC filter.
Filtering of 1-bit digital input data MDATAm for each channel m (m = 0 to 2 or 3) through the SINC filters is synchronized by the MCLKm clock.
Figure 41.2 shows the configuration of a SINC filter.

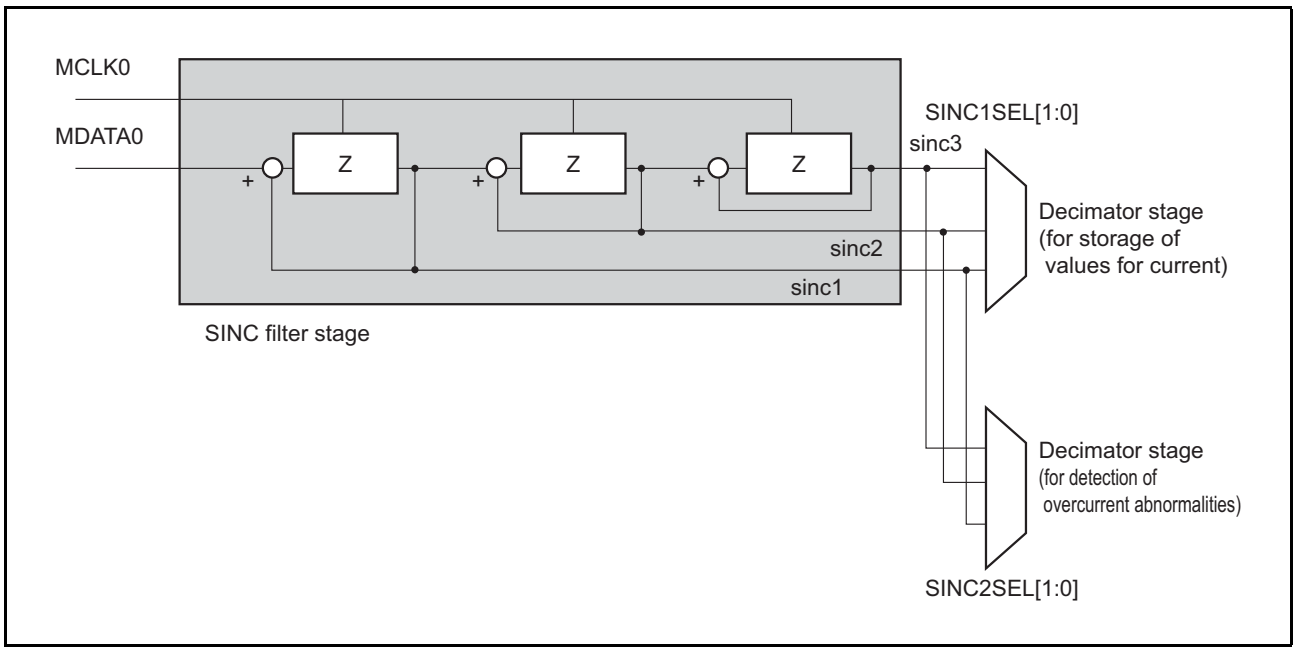

Figure 41.2 Configuration of a SINC Filter (Example of Channel 0 (U))

The orders of the filters (sinc3, sinc2, or sinc1) for storage of values for current and for the detection of abnormal overcurrents can be selected with the SINC1SEL[1:0] bits and the SINC2SEL[1:0] bits in the UVWCTL register (for unit 0) and XYZCTL register (for unit 1), respectively. Table 41.3 lists the SINC filter order settings.

Table 41.3 SINC Filter Order Settings

SINC1SEL[1:0] or SINC2SEL[1:0] Settings	SINC Filter Order
00b	3 (sinc3)
01b	1 (sinc1)
10b	2 (sinc2)

41.3.2 Decimation

Each DSMIF has three 24-bit divider stages which handle decimation.
The SINC filter output on each channel m (m = 0 to 2 or 3) is filtered by the decimation clock divided by a value from 4 to 256.
Figure 41.3 shows the configuration of the decimator.

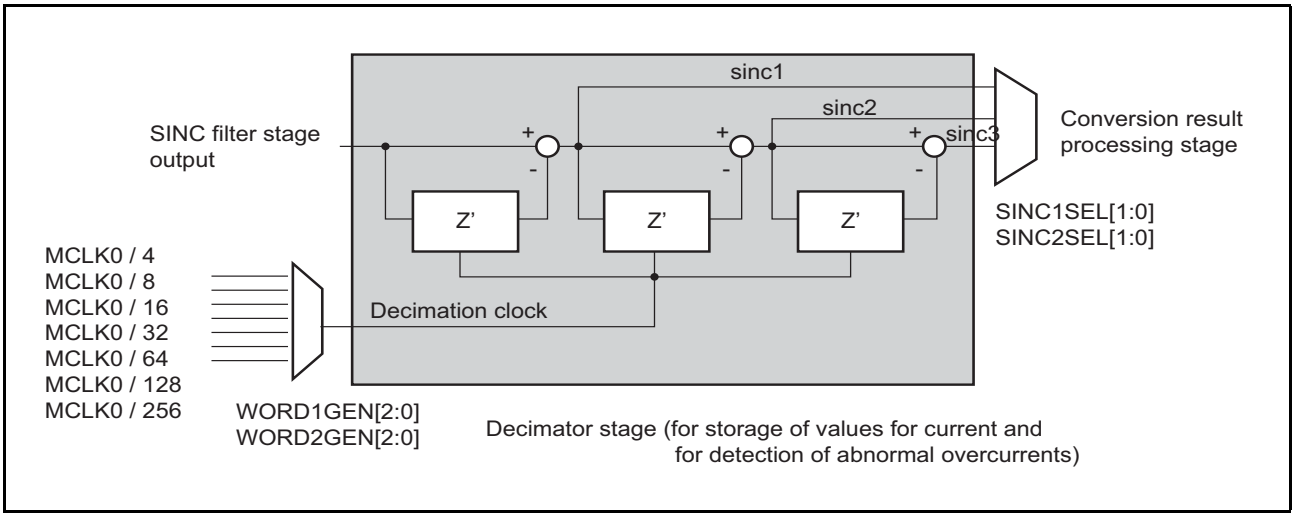

Figure 41.3 Configuration of the Decimator (Example of Channel 0 (U))

The division ratio of the decimation clocks for detection of abnormal overcurrents and for the storage of values for current are selected with the WORD1GEN[2:0] and WORD2GEN[2:0] bits in the UVWCTL register (for unit 0) and XYZCTL register (for unit 1), respectively.
Table 41.4 lists the decimation clock settings and resolutions.

Table 41.4 Decimation Clock Settings and Resolutions

WORD1GEN[2:0] or WORD2GEN[2:0] Settings	Division Ratio (m = 0 to 2, 3)	Resolution
000b	MCLKm/4	6 bits
010b	MCLKm/8	9 bits
011b	MCLKm/16	12 bits
100b	MCLKm/32	15 bits
101b	MCLKm/64	16 bits
110b	MCLKm/128	16 bits
111b	MCLKm/256	16 bits

Furthermore, the orders of the filters (sinc3, sinc2, or sinc1) for storage of values for current and for the detection of abnormal overcurrents can be selected with the SINC1SEL[1: 0] bits and the SINC2SEL[1:0] bits in the UVWCTL register (for unit 0) and XYZCTL register (for unit 1), respectively. For the SINC filter order settings, see Table 41.3, SINC Filter Order Settings.

41.3.3 Processing of Conversion Results

41.3.3.1 Conversion of Values for Current and Capture of Values in Response to Crest and Trough Triggers

As facilities for current conversion, each DSMIF has current value registers 1 (U1DATA, V1DATA, W1DATA, and X1DATA) for storing the results of conversion on the corresponding channels, current value crest trigger capture registers (U1CDATA, V1CDATA, W1CDATA, and X1CDATA) and current value trough trigger capture registers (U1VDATA, V1VDATA, W1VDATA, and X1VDATA). The capture registers hold values for current captured in response to the crest and trough triggers from the PWM timer selected for input by using the event link controller (ELC). Figure 41.4 the configuration for the conversion of values for current.

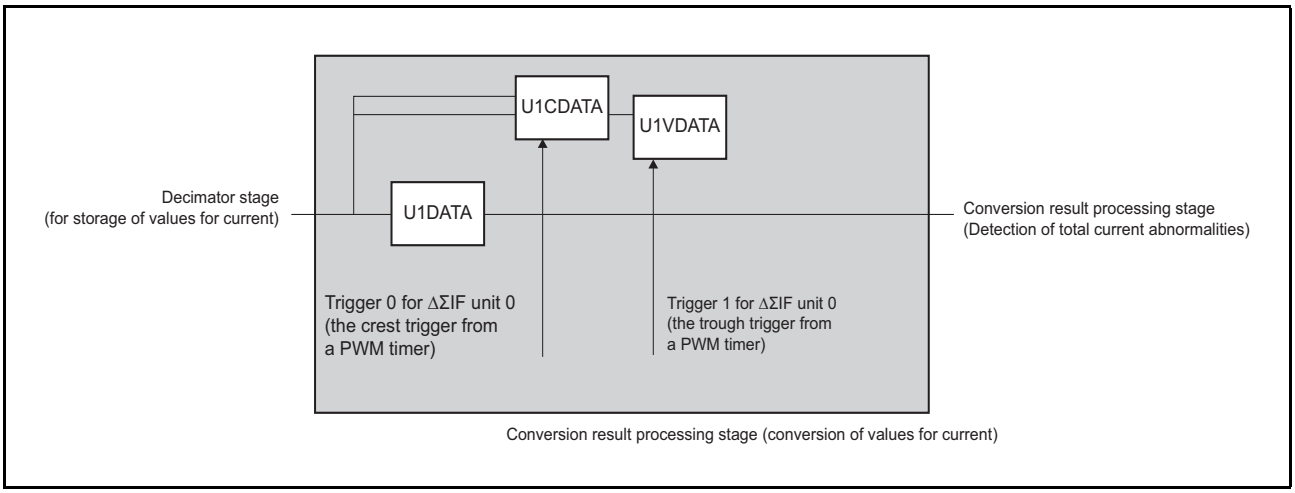

Figure 41.4 Configuration for the Conversion of Values for Current and Capture of Values in Response to Crest and Trough Triggers (Example of Channel 0 (U))

Also, as the results of conversion of values for current, 24-bit values for current from the decimator stage are filtered in accord with the bit shift setting of the BITSHIFT1[3:0] bits in the UVWCTL register (for unit 0) or the XYZCTL register (for unit 1) and stored as 16-bit values for current.

Table 41.5 Correspondence between BITSHIFT1[3:0] Settings and 16-Bit Values for Current

BITSHIFT1[3:0] Settings	16-Bit Values Selected from 24-Bit Values Output by the Decimator*1
0000b	[23:8]
0001b	[20:5]
0010b	[17:2]
0011b	[15:0]
0100b	[14:0], 0b
0101b	[13:0], 00b
0110b	[11:0], 0000b
0111b	[9:0], 00 0000b
1000b	[8:0], 000 0000b
1001b	[7:0], 0000 0000b
1010b	[6:0], 0 0000 0000b
1011b	[5:0], 00 0000 0000b
1100b	[4:0], 000 0000 0000b

Note 1. When BITSHIFT1[3:0] = 0100b to 1100b, the lower-order bits are padded with 0. For details, see Figure 41.8, Relationship between the Settings for Filtering and the Format of Values for Current.

Crest and trough trigger capturing allows capturing of values for current at the time of crest and trough triggers by setting the crest trigger (or trough trigger) from a timer (MTU3a, GPTa) set to PWM mode as trigger 0 for ΔΣ IF unit n (or trigger 1 for ΔΣ IF unit n) by using the event link controller (ELC).
Table 41.6 lists the crest and trough trigger settings. For details of the ELC, see section 16, Event Link Controller (ELC).

Table 41.6 Crest and Trough Trigger Settings

Unit	Crest and Trough Triggers
0 (U, V, W)	Crest trigger: trigger 0 for ΔΣ IF unit 0
	Trough trigger: trigger 1 for ΔΣ IF unit 0
1 (X)	Crest trigger: trigger 0 for ΔΣ IF unit 1
	Trough trigger: trigger 1 for ΔΣ IF unit 1

41.3.3.2 Detection of Overcurrent Abnormalities

For the detection of overcurrent abnormalities, 24-bit values for current from the decimator stage are filtered according to the bit shift setting of the BITSHIFT2[3:0] bits in the UVWCTL register (for unit 0) or the XYZCTL register (for unit 1), and the 16-bit values thus obtained are stored as the results of conversion of values for current.

Table 41.7 Correspondence between BITSHIFT2[3:0] Settings and 16-Bit Values for Current

BITSHIFT2[3:0] Settings	16-Bit Values Selected from 24-Bit Values Output by the Decimator*1
0000b	[23:8]
0001b	[20:5]
0010b	[17:2]
0011b	[15:0]
0100b	[14:0], 0b
0101b	[13:0], 00b
0110b	[11:0], 0000b
0111b	[9:0], 00 0000b
1000b	[8:0], 000 0000b
1001b	[7:0], 0000 0000b
1010b	[6:0], 0 0000 0000b
1011b	[5:0], 00 0000 0000b
1100b	[4:0], 000 0000 0000b

Note 1. When BITSHIFT1[3:0] = 0100b to 1100b, the lower-order bits are padded with 0. For details, see Figure 41.8, Relationship between the Settings for Filtering and the Format of Values for Current.

If a 16-bit value for current is not in the range defined by the upper and lower limits set by the UVWIUNCMP and UVWIOVCMP registers (for unit 0) and the XYZIUNCMP or XYZIOVCMP registers (for unit 1), the overcurrent abnormality detection error signal is generated. For details of the output of error sources, see section 41.4, Error Sources. Figure 41.5 shows the configuration for the detection of overcurrent abnormalities.

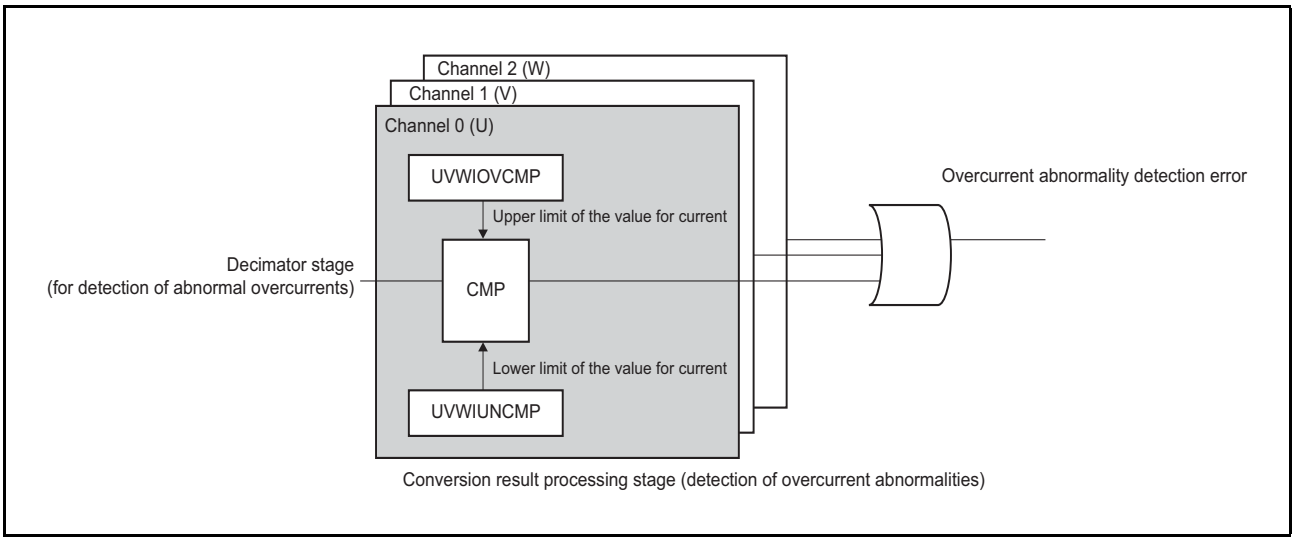

Figure 41.5 Detection of Overcurrent Abnormalities (Example of Unit 0 (U, V, and W))

41.3.3.3 Detection of Short-Circuit Abnormalities

For the detection of short-circuit abnormalities, a dedicated 13-bit counter counts the number of times 0 or 1 is consecutively input as 1-bit digital input data MDATAm (m = 0 to 2, 3). When the number of consecutive times exceeds the threshold for “0”- or “1”-valued data set in the UVWSCUNCMP and UVWSCOVCMP registers (for unit 0) or the XYZSCUNCMP and XYZSCOVCMP registers (for unit 1), the short-circuit abnormality detection error signal is generated. For details of the output of error sources, see section 41.4, Error Sources.
Figure 41.6 shows the configuration for the detection of short-circuit abnormalities.

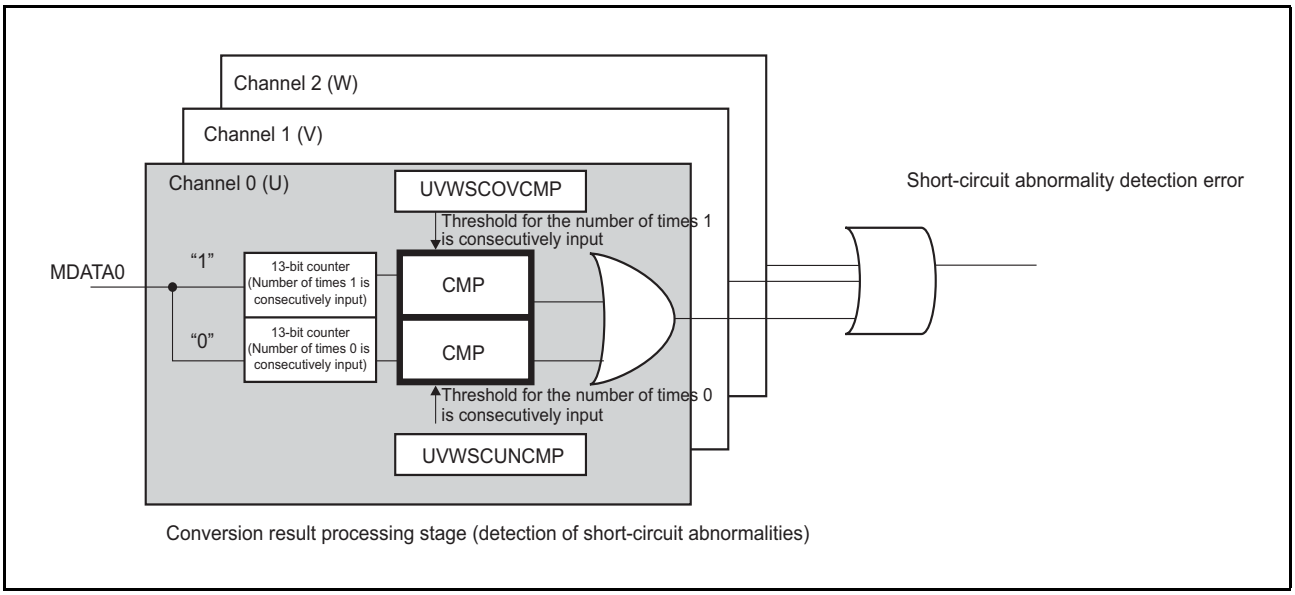

Figure 41.6 Detection of Short-Circuit Abnormalities (Example of Unit 0 (U, V, and W))

41.3.3.4 Detection of Total Current Abnormalities (only for unit 0 (U, W, and W))

In total current abnormality detection, a total current abnormality detection error signal is generated when the sum of the values for current after conversion on each channel of unit 0 is not in the range specified by the lower and upper limit settings in the UVWIGUNCMP and UVWIGOVCMP registers. For details of the output of error sources, see section 41.4, Error Sources.

Figure 41.7 shows the configuration for the detection of total current abnormalities.

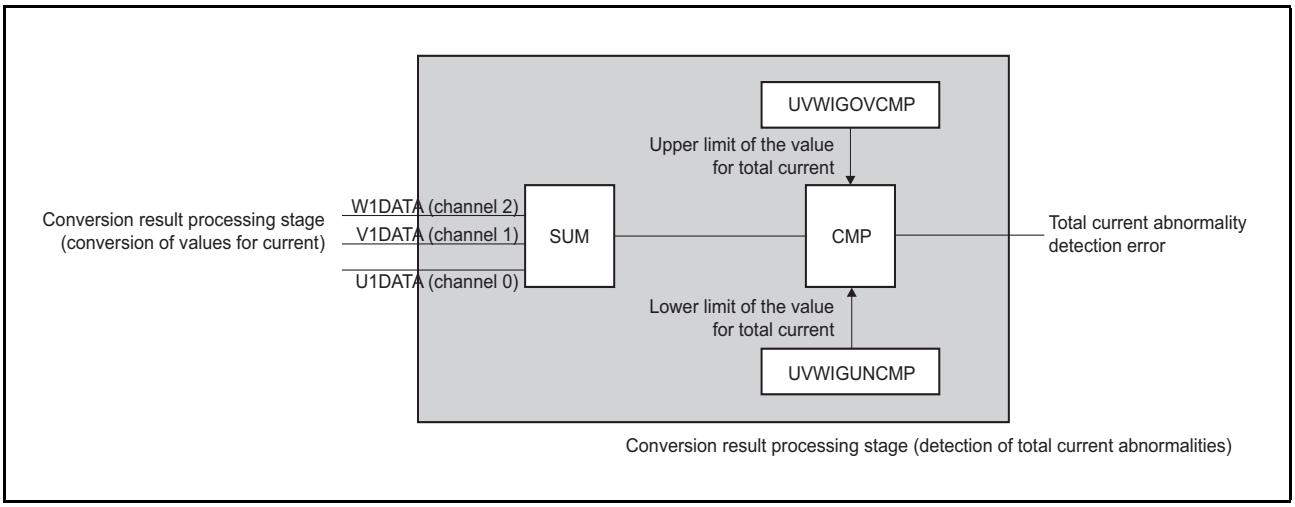

Figure 41.7 Detection of Total Current Abnormalities (Example of Unit 0 (U, V, and W)

41.3.4 Settings for Operating Clock Signals

In the DSMIF, the DSCR register is used to select whether the operating clock MCLKm (m = 0 to 2, 3) is to be supplied by a ΔΣ modulator external to the LSI (slave operation) or from the clock generator (master operation).

In master operation, the frequency of the DSCLKm clock is selectable as 6.25 MHz, 9.375 MHz, 12.5 MHz, 18.75 MHz, or 25 MHz. The active sense of the clock signal is selectable in both master and slave operation. For details of the DSCR register, see section 7, Clock Generation Circuit.

41.3.5 Settings for Filtering

Table 41.8 lists the settings for filtering by the individual registers and Figure 41.8 shows the relationship between the settings for filtering and the format of values for current.

Table 41.8 Settings for Filtering (The Only Allowed Combinations of the Register Values)

SINC Filter Order	WORD1GEN[2:0] or WORD2GEN[2:0] Settings	MSB	BITSHIFT1[3:0] or BITSHIFT2[3:0] Settings	Resolution
3 (sinc3)	010b	Bit 8	1000b	9 bits
	011b	Bit 11	0110b	12 bits
	100b	Bit 14	0100b	15 bits
	101b	Bit 17	0010b	16 bits
	110b	Bit 20	0001b	16 bits
	111b	Bit 23	0000b	16 bits
2 (sinc2)	011b	Bit 7	1001b	8 bits
	100b	Bit 9	0111b	10 bits
	101b	Bit 11	0110b	12 bits
	110b	Bit 13	0101b	14 bits
	111b	Bit 15	0011b	16 bits
1 (sinc1)	100b	Bit 4	1100b	5 bits
	101b	Bit 5	1011b	6 bits
	110b	Bit 6	1010b	7 bits
	111b	Bit 7	1001b	8 bits

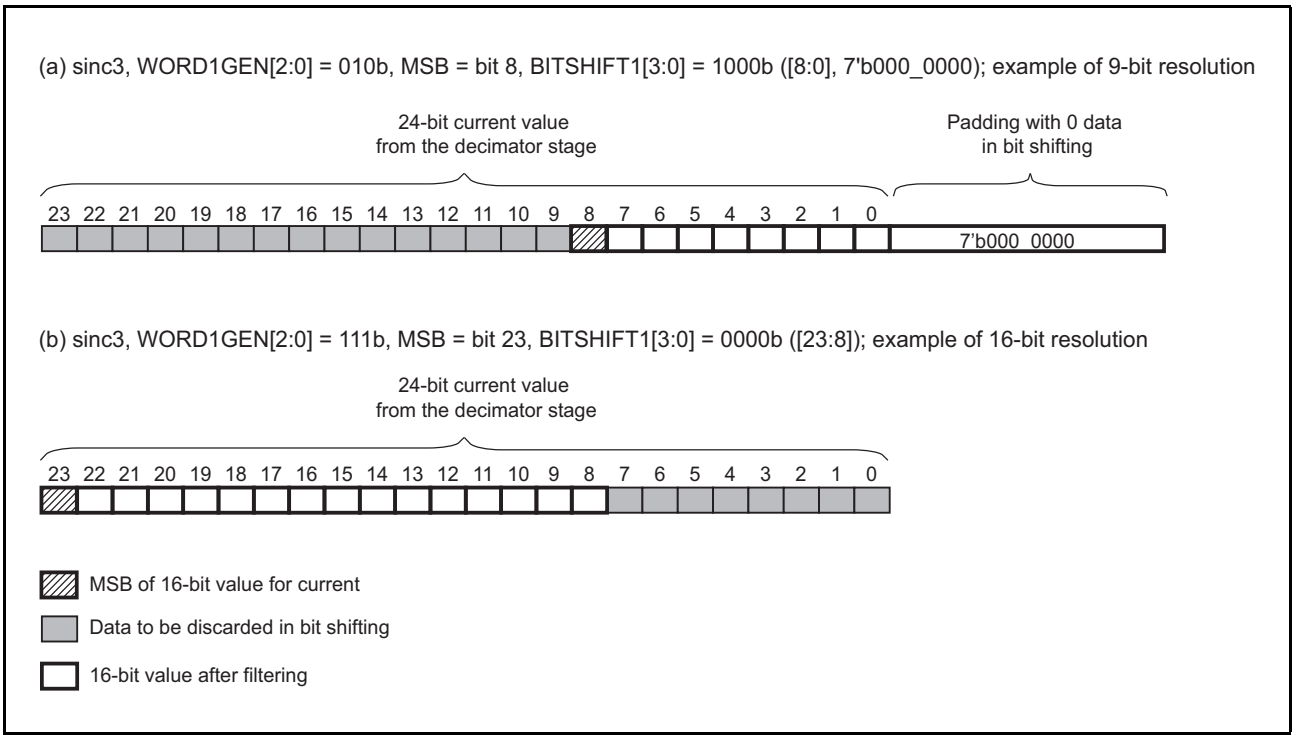

Figure 41.8 Relationship between the Settings for Filtering and the Format of Values for Current

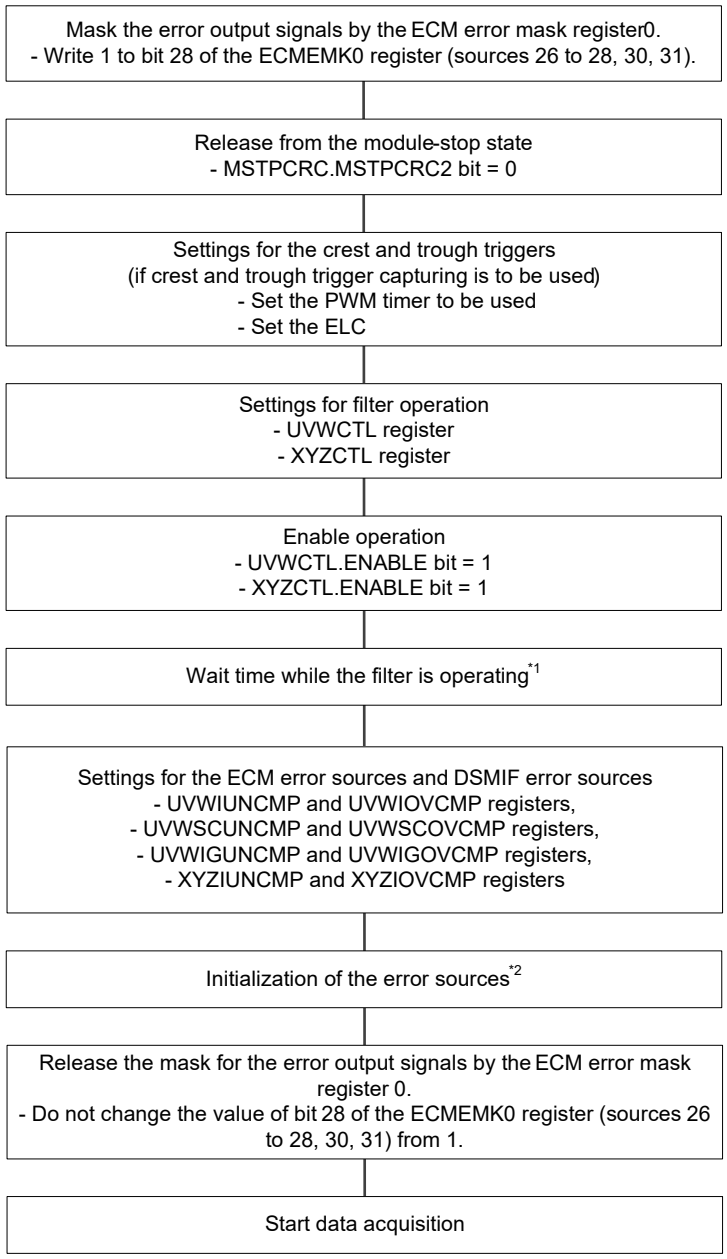
41.3.6 Setting Examples

Figure 41.9 shows the setting procedure.



Note 1. The wait time while the filter is operating is obtained as follows:
[Period of MCLK] × [Number of SINC stages (1 to 3)] + [Period of decimation clock (max.)] × (6 + [Number of SINC stages (1 to 3)]) + [5 µs]
Use the period of decimation clock with its maximum allowable value.

Note 2. After release from the module-stop state, be sure to make initial settings for error sources in the error control module (ECM). For details, see section 41.5, Usage Notes.

Figure 41.9 Setting Example of the Error Control Module

41.3.7 Filtering

Figure 41.10 and Figure 41.11 show the timing for sampling in SINC3 filtering and decimation by the ΔΣ interfaces. Settings (1), (2), and (3) below can be made for filter clocks (MCLKn (n = 0 to 3) input to the ΔΣ interfaces by using the DSCR register. For the DSCR register, see section 7, Clock Generation Circuit.

(1) Select the source of the signal for input to MCLKn as being generated within (in master operation) or outside (in slave operation) the RZ/T1.
(2) If the clock is to be generated within the RZ/T1, select one of the five available frequencies.
(3) Select inversion or non-inversion for MCLKn.

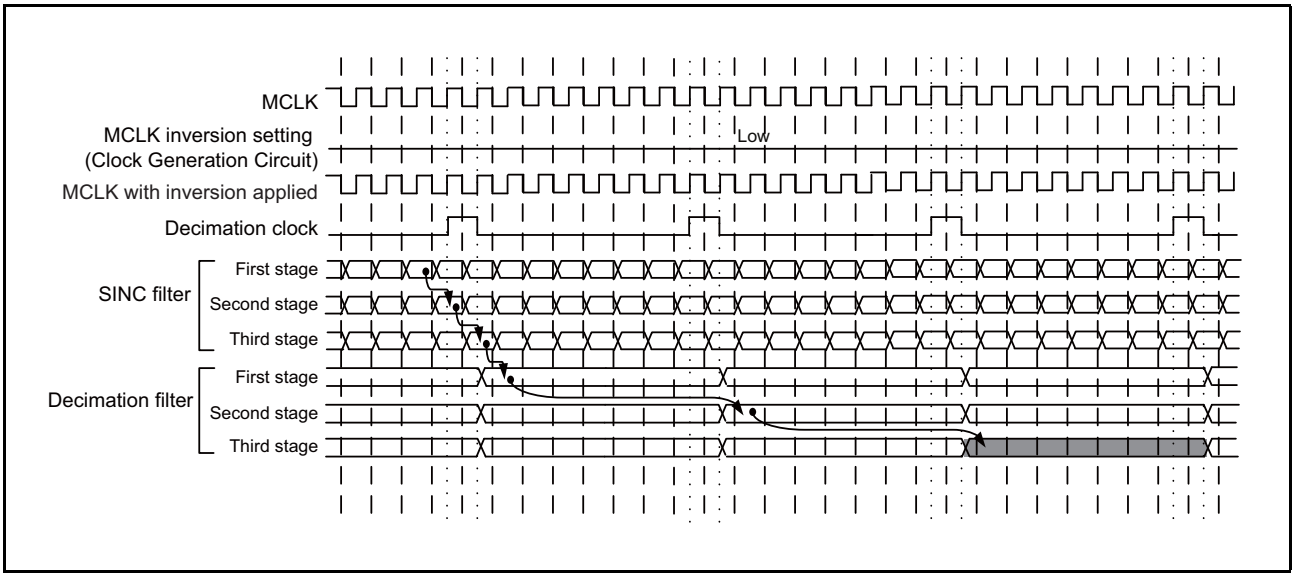


Figure 41.10 Operation when MCLKn is not Inverted

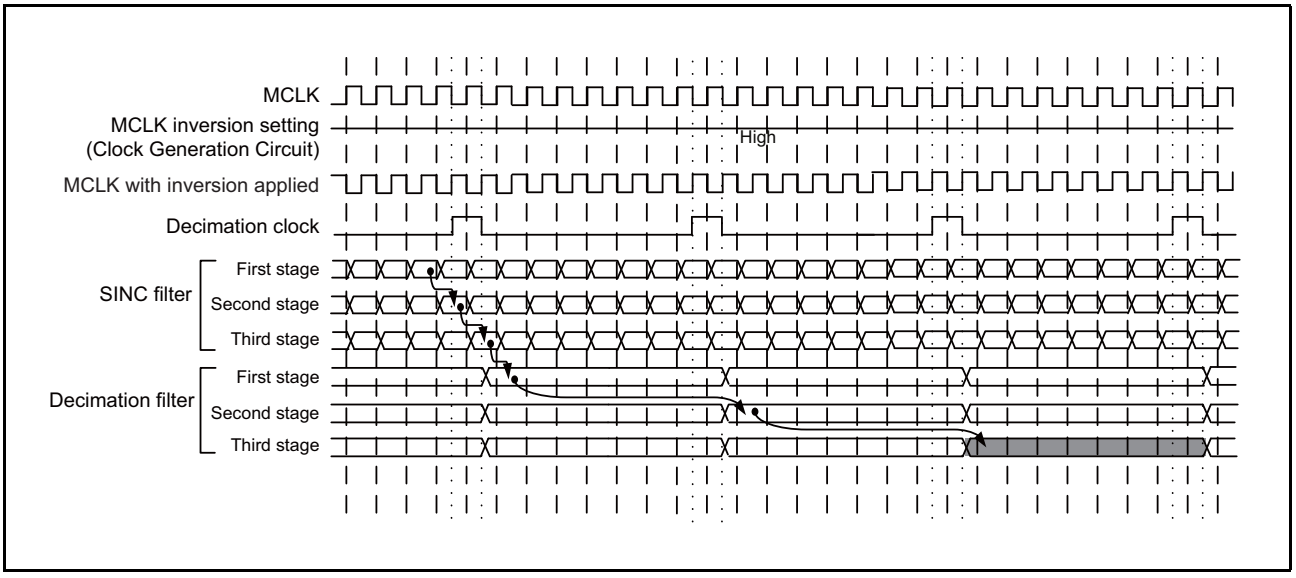

Figure 41.11 Operation when MCLKn is Inverted

41.4 Error Sources

The DSMIF can output the following three error signals to the error control module (ECM).

- Overcurrent abnormality detection error signal (in units 0 and 1)
- Short-circuit abnormality detection error signal (in units 0 and 1)
- Total current abnormality detection error signal (in unit 0)

For details of the error control module (ECM), see section 42, Error Control Module (ECM).

41.5 Usage Notes

41.5.1 Initial Settings for Error Sources after Release from the Module-Stop State

The DSMIF always outputs a short-circuit abnormality detection error signal after release from the module-stop state. Clear the error flag once before enabling error handling by the ECM.

(1) Mask the error output signals by the ECM error mask register 0 (sources 26 to 28, 30, 31). Do not change bit 28 from 1.
(2) Enable filter operation.
(3) Wait while the filter is operating.
(4) Clear the error status register of the DSMIF.*1
(5) Clear the error state of the ECM DSMIF error numbers (No. 26 to 28, 30 and 31) of the ECM error source status clear trigger register 0.
(6) Enable the ECM DSMIF error numbers (No. 26 to 28, 30 and 31).
(7) Release the mask for the error output signals by the ECM error mask register 0 (sources 26 to 28, 30, 31). Do not change bit 28 from 1.
(8) If a short-circuit abnormality detection error occurs, read the UVWSTA and XYZSTA registers to check if the error occurred in one of channels 0 to 3 (U, V, W, and X).*2

For details, see section 41.3.6, Setting Examples.

Note 1. Performing step (4) after step (5) does not create any problem.
Note 2. If the ECM is reset by an ECM error, the UVWSTA and XYZSTA registers are initialized, so read the flags retained in the corresponding error source status register of the ECM. However, if this is the case, you cannot judge in which of channels 0 to 2 (U, V, and W) of unit 0 the error occurred.

For details of the error control module (ECM), see section 42, Error Control Module (ECM).

41.5.2 Current Value on Detection of an Overcurrent

If a value for current increases and an overflow occurs on the related current value register, the read value of the current value register is not FFFFh but 0000h. For this reason, for the detection of overcurrent abnormalities, generate an error by using the overcurrent abnormality detection function and do not refer to the value of the current value register.

42. Error Control Module (ECM)

This section describes an error control module (ECM).

42.1 Overview

The error control module (ECM) collects error output signals coming from individual peripheral modules. It also outputs error signals from the error output pin (ERROROUT#) and generates error interrupts and internal reset signals. Table 42.1 describes the ECM specifications and Figure 42.1 shows the block diagram of ECM.

Table 42.1 Specifications of ECM

Item	Description
Safety processing	ECM can handle the following processing in response to error signal inputs from individual modules. • Error flag set ECM has flags that indicate the state of error occurrence for individual error sources. • ECM maskable interrupt generation Maskable interrupt generation can be controlled (enabled or disabled) for individual error sources. • ECM non-maskable interrupt generation Non-maskable interrupt generation can be controlled (enabled or disabled) for individual error sources. • ECM reset (Internal reset) Internal reset generation can be controlled (enabled or disabled) for individual error sources. • Error signal output from the ERROROUT# pin Error signal output and mask control (enable or disable) are possible for individual error sources. Output can be toggled in response to a CMTW timer input or made at a fixed level.
Error status	ECM incorporates error status registers, whose error flag values can be used to check whether the corresponding error sources have been generated.
Debug, self-diagnosis	• Pseudo errors can be generated for debug and self-diagnosis. The operation during injection of pseudo errors is identical to that for the occurrence of real errors. All configurations for the mask to the error pin output, interrupt, or internal reset apply in the same way. In addition, extended pseudo errors can be used for error detection for functional safely. • ECM incorporates a loop-back function of the error pin output that is used to diagnose the path to the error output pin. The status of the error output pin is reflected to an internal register and can be confirmed by reading the register.
Delay timer timeout	ECM has a function of outputting an error signal or resetting ECM when the delay timer starts at the same time with generation of an ECM maskable interrupt or an ECM non-maskable interrupt and a delay timer overflow occurs because the delay timer cannot be stopped during the interrupt processing.
Others	ECM has a duplexed structure (master and checker) for redundancy.

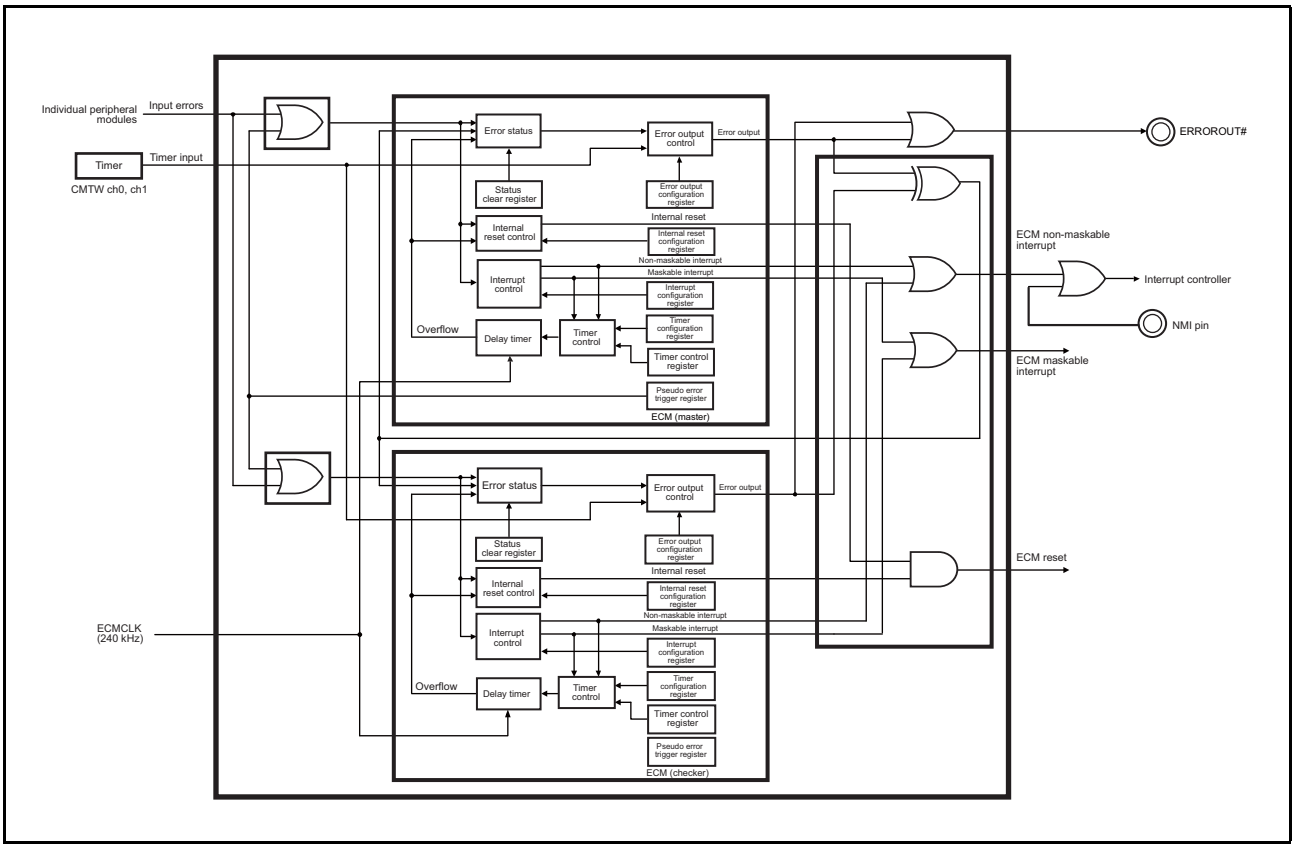

Figure 42.1 Block Diagram of ECM

Table 42.2 shows the error input to ECM.

Table 42.2 ECM Error Input (1 / 2)

Error Source Number	Module	Function
1	WDTA	WDTA underflow/refresh error (for Cortex-R4)
2	WDTA	WDTA underflow/refresh error (for Cortex-M3) (for products incorporating an R-IN engine)
3	IWDTa	IWDTa underflow/refresh error
4	—	Reserved
5	Cortex-R4 cache	1-bit or 2-bit ECC error in the instruction cache (Tag RAM)
6		1-bit or 2-bit ECC error in the instruction cache (Data RAM)
7		1-bit ECC error in the data cache (Tag/Dirty RAM)
8		2-bit ECC error in the data cache (Tag/Dirty RAM)
9		1-bit ECC error in the data cache (Data RAM)
10		2-bit ECC error in the data cache (Data RAM)
11	Cortex-R4 RAM	1-bit ECC error in the ATCM
12		2-bit ECC error in the ATCM
13		1-bit ECC error in the BTCM
14		2-bit ECC error in the BTCM
15	Extended internal SRAM	1-bit ECC error in the IRAM or DRAM
16		2-bit ECC error in the IRAM or DRAM
17	RSCAN	1-bit ECC error in the RSCAN RAM
18		2-bit ECC error in the RSCAN RAM
19		RSCAN overflow error
20	Clock monitor circuit (CLMA)	Main clock oscillation stop detection

35	—	Extended pseudo error 35*1
36	—	Extended pseudo error 36*1
37	—	Extended pseudo error 37*1
38	—	Extended pseudo error 38*1
39	—	Extended pseudo error 39*1
40	—	Extended pseudo error 40*1
41	—	Extended pseudo error 41*1
42 to 92	—	Reserved

Table 42.2 ECM Error Input (2 / 2)

Error Source Number	Module	Function
93	Error control module (ECM)	Compare error
94		Delay timer overflow error
95		Error set by the ECMmESET register
96		Loopback error

Note 1. A pseudo error can be generated if the corresponding bit in the ECM pseudo error trigger register (ECMPEn) is set by software. For details, see section 42.3.3, Pseudo Error Generation.

42.2 Registers

42.2.1 ECM Master/Checker Error Set Trigger Register (ECMmESET (m = M or C))

The ECMmSET (m = M or C) register controls the output of the ERROROUT# pin. Setting the ECMmEST bit to 1 can set the output of the ERROROUT# pin to the active level (low level). The ERROROUT# pin output cannot be masked. Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers. This register is always read as 00h.

Address(es): ECMMESET: A007 D000h
ECMCESET: A007 D040h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECMmEST
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECMmEST	Error Set Trigger	0: Writing 0 is invalid. 1: Sets the output level of the ERROROUT# pin to the active level (low level).	W
b7 to b1	—	Reserved	The write value should be 0.	W

Note 1. Setting the ECMmESET register will set the ECMmSSE228 bit of the ECMmESSTR2 register (ECM compare error). Therefore, to use the ECMmESET register to control the ERROROUT# pin, follow the procedure below.
1. Set the ECMEMK228 bit of the ECMEMK2 register to “masked”.
2. Prevent the generation of interrupts by setting the ECMMIE228 bit of the ECMMICFG2 register to “prohibited” and the ECMNMIE228 bit of the ECMNMICFG2 register to “prohibited”.
3. Prevent generation of an internal reset by setting the ECMIRE228 bit of the ECMIRCFG2 register to “prohibited”.
4. Set the error output bit in the ECMmESET register.
5. Clear error flags by setting the ECMCLSSE228 bit of the ECMESSTC2 register.
6. Make the following settings, as necessary, to change back the ECM compare error settings.
   - To enable the error output from the ERROROUT# pin, set the ECMEMK228 bit in the ECMEMK2 register to “not masked”.
   - To enable an error interrupt, set the ECMMIE228 bit in the ECMMICFG2 register or the ECMNMIE228 bit in the ECMNMICFG2 register to “enabled”.
   - To enable an ECM reset, set the ECMIRE228 bit in the ECMIRCFG2 register to “enabled”.

Note 2. When the error output is set by the ECMmESET register, an error state is retained even after all error sources that have not been masked in the ECMESSTCn register are cleared, and the low level is output from the ERROROUT# pin while the pin stays active. To clear an error state, perform clear processing on the ECMmECLR register.

42.2.2 ECM Master/Checker Error Clear Trigger Register (ECMmECLR (m = M or C))

The ECMmECLR (m = M or C) register controls the output from the ERROROUT# pin. When the ECMmECT bit is set to 1, the output of the ERROROUT# pin can be set to the inactive level (high level) if there is no other error sources that set the ERROROUT# pin to the active level (low level).
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers. This register is always read as 00h.

Address(es): ECMMECLR: A007 D004h
ECMCECLR: A007 D044h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	ECMm ECT
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECMmECT	Error Clear Trigger	0: Writing 0 has no effect. 1: Sets the output level of the ERROROUT# pin to the inactive level (high level). Note that, however, this bit cannot be used to clear an error while ECM error output clear is disabled. For details, see section 42.3.6, Setting of Disabling Error Output Clear.	W
b7 to b1	—	Reserved	The write value should be 0.	W

Note: Clearing the output of the error pin is only possible if all error sources, not masked by ECMEMK0, ECMEMK1, or ECMEMK2, are cleared beforehand. Setting the ECMmECT bit in this register will set the output of the ERROROUT# pin to the inactive level (high level).
If an error state is generated due to the error output set by ECMmESET, use this register to clear the error state.
Follow the procedure below to “clear” error states.

1. Set all bits corresponding to an error in the ECMESSTC0, ECMESSTC1, and ECMESSTC2 registers to clear the error state indicator.
2. To mask the output of error signals due to any error sources, set all bits corresponding to an error in the ECMEMK0, ECMEMK1, and ECMEMK2 registers to “masked”.
3. To prevent unintended processing in response to an ECM comparison error (error source 93), set the ECMMIE228, ECMNMIE228, and ECMIRE228 bits in the ECMMICFG2, ECMNMICFG2, and ECMIRCFG2 registers to “prohibited”.
4. Clear the output on the ERROROUT# pin by using the ECMMECT and ECMCECT bits in the ECMMECLR and ECMCECLR registers. At this time, an ECM comparison error will be generated.
5. Use software to set up the following interval of waiting until generation of the ECM compare error is reflected in the ECMESSTR2 register.
   (3 × ECMCLK) + (5 × PCLKD)
   In this product, the waiting time is about 12.6 µs because ECMCLK = 240 kHz and PCLKD = 75 MHz.
6. Use the ECMCLSSE228 bit in the ECMESSTC2 register to “clear” the ECM comparison error.
7. As required, restore the settings of the ECMEMK0, ECMEMK1, and ECMEMK2 registers which were changed in step 2 above.
8. As required, restore the settings of the ECMMICFG2, ECMNMICFG2, and ECMIRCFG2 registers which were changed in step 3 above.

42.2.3 ECM Master/Checker Error Source Status Register 0 (ECMmESSTR0 (m = M or C))

The ECMmESSTR0 (m = M or C) register is a flag register that indicates whether individual error sources occurred. This register is cleared with the corresponding bits in the ECM error source status clear trigger register 0 (ECMESSTC0) set, or with the RES# pin reset. This register is not cleared by occurrence of other reset sources.

Address(es): ECMMESSTR0: A007 D008h
ECMCESSTR0: A007 D048h

b31	ECMmSSE031	Error Source Status 32	Indicates occurrence of a DOC operation error (error source 32). 0: Error not occurred 1: Error occurred	R

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, this bit is read as 0.

42.2.4 ECM Master/Checker Error Source Status Register 1 (ECMmESSTR1 (m = M or C))

The ECMmESSTR1 (m = M or C) register is a flag register that indicates whether individual error sources occurred. This register is cleared with the corresponding bits in the ECM error source status clear trigger register 1 (ECMESSTC1) set, or with the RES# pin reset. This register is not cleared by occurrence of other reset sources.

Address(es): ECMMESSTR1: A007 D00Ch
ECMCESSTR1: A007 D04Ch

b7	ECMmSSE107	Error Source Status 40	Indicates occurrence of extended pseudo error 40 (error source 40)*1. 0: Error not occurred 1: Error occurred	R
b8	ECMmSSE108	Error Source Status 41	Indicates occurrence of extended pseudo error 41 (error source 41)*1. 0: Error not occurred 1: Error occurred	R
b31 to b9	—	Reserved	These bits are read as 0.	R

Note 1. An error occurs when the ECMPE1.ECMPE102 to ECMPE1.ECMPE108 bit is set by software.

42.2.5 ECM Master/Checker Error Source Status Register 2 (ECMmESSTR2 (m = M or C))

The ECMmESSTR2 (m = M or C) register is a flag register that indicates whether individual error sources occurred. Bits 30 to 28 of this register are cleared with the corresponding bits in the ECM error source status clear trigger register 2 (ECMESSTC2) set, or with the RES# pin reset. This register is not cleared by occurrence of other reset sources. Note that bit 31 of this register is not reset.

Address(es): ECMMESSTR2: A007 D010h
ECMCESSTR2: A007 D050h

b31 to b8	—	Reserved	The write value should be 0.	W

42.2.7 ECM Error Pulse Configuration Register (ECMEPCFG)

The ECMEPCFG register controls output to the ERROROUT# pin. For details, see section 42.3.1, Operations for Error Output.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D080h

b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.2.8 ECM Maskable Interrupt Configuration Register 0 (ECMMICFG0)

The ECMMICFG0 register controls generation of ECM maskable interrupts due to occurrence of individual error sources.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D084h

b14	ECMMIE014	ECM Maskable Interrupt Generation Control 15	Enables or disables a maskable interrupt due to occurrence of a 1-bit ECC error in the IRAM or DRAM (error source 15). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b15	ECMMIE015	ECM Maskable Interrupt Generation Control 16	Enables or disables a maskable interrupt due to occurrence of a 2-bit ECC error in the IRAM or DRAM (error source 16). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b16	ECMMIE016	ECM Maskable Interrupt Generation Control 17	Enables or disables a maskable interrupt due to occurrence of a 1-bit ECC error in the RSCAN RAM (error source 17). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b17	ECMMIE017	ECM Maskable Interrupt Generation Control 18	Enables or disables a maskable interrupt due to occurrence of a 2-bit ECC error in the RSCAN RAM (error source 18). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b18	ECMMIE018	ECM Maskable Interrupt Generation Control 19	Enables or disables a maskable interrupt due to occurrence of an RSCAN overflow error (error source 19). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b19	ECMMIE019	ECM Maskable Interrupt Generation Control 20	Enables or disables a maskable interrupt due to occurrence of an error of main clock oscillation stop detection (error source 20). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	ECMMIE020	ECM Maskable Interrupt Generation Control 21	Enables or disables a maskable interrupt due to occurrence of an error of CLMA0 oscillation stop detection (PLL0) (error source 21). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b21	ECMMIE021	ECM Maskable Interrupt Generation Control 22	Enables or disables a maskable interrupt due to occurrence of an error of CLMA1 oscillation stop detection (PLL1) (error source 22). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b22	ECMMIE022	ECM Maskable Interrupt Generation Control 23	Enables or disables a maskable interrupt due to occurrence of an error of CLMA2 oscillation stop detection (LOCO) (error source 23). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b23	ECMMIE023	ECM Maskable Interrupt Generation Control 24	Enables or disables a maskable interrupt due to occurrence of a 12-bit A/D converter unit 0 overwrite interrupt (error source 24). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b24	ECMMIE024	ECM Maskable Interrupt Generation Control 25	Enables or disables a maskable interrupt due to occurrence of a 12-bit A/D converter unit 1 overwrite interrupt (error source 25). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b25	ECMMIE025	ECM Maskable Interrupt Generation Control 26	Enables or disables a maskable interrupt due to occurrence of a UVW overcurrent abnormality detection error (error source 26). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b26	ECMMIE026	ECM Maskable Interrupt Generation Control 27	Enables or disables a maskable interrupt due to occurrence of a UVW total current abnormality detection error (error source 27). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b27	ECMMIE027	ECM Maskable Interrupt Generation Control 28	Enables or disables a maskable interrupt due to occurrence of a UVW short circuit abnormality detection error (error source 28). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b28	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b29	ECMMIE029	ECM Maskable Interrupt Generation Control 30	Enables or disables a maskable interrupt due to occurrence of an X overcurrent abnormality detection error (error source 30). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b30	ECMMIE030	ECM Maskable Interrupt Generation Control 31	Enables or disables a maskable interrupt due to occurrence of an X short circuit abnormality detection error (error source 31). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b31	ECMMIE031	ECM Maskable Interrupt Generation Control 32	Enables or disables a maskable interrupt due to occurrence of a DOC operation error (error source 32). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.9 ECM Maskable Interrupt Configuration Register 1 (ECMMICFG1)

The ECMMICFG1 register controls generation of ECM maskable interrupts due to occurrence of individual error sources.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.2.10 ECM Maskable Interrupt Configuration Register 2 (ECMMICFG2)

The ECMMICFG2 register controls generation of ECM maskable interrupts due to occurrence of individual error sources.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b1	ECMMIE001	ECM Non-maskable Interrupt Generation Control 2	Enables or disables a non-maskable interrupt due to occurrence of a WDT overflow/refresh error (for Cortex-M3) (error source 2).*1 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b2	ECMNMIE002	ECM Non-maskable Interrupt Generation Control 3	Enables or disables a non-maskable interrupt due to occurrence of an IWDTa overflow/refresh error (error source 3). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ECMNMIE004	ECM Non-maskable Interrupt Generation Control 5	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error (with correction) and 2-bit ECC error (without correction) in the instruction cache (Tag RAM) (error source 5). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b5	ECMNMIE005	ECM Non-maskable Interrupt Generation Control 6	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error (with correction) and 2-bit ECC error (without correction) in the instruction cache (Data RAM) (error source 6). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b6	ECMNMIE006	ECM Non-maskable Interrupt Generation Control 7	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error in the data cache (Tag/Dirty RAM) (error source 7). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b7	ECMNMIE007	ECM Non-maskable Interrupt Generation Control 8	Enables or disables a non-maskable interrupt due to occurrence of a 2-bit ECC error in the data cache (Tag/Dirty RAM) (error source 8). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b8	ECMNMIE008	ECM Non-maskable Interrupt Generation Control 9	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error in the data cache (Data RAM) (error source 9). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b9	ECMNMIE009	ECM Non-maskable Interrupt Generation Control 10	Enables or disables a non-maskable interrupt due to occurrence of a 2-bit ECC error in the data cache (Data RAM) (error source 10). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b10	ECMNMIE010	ECM Non-maskable Interrupt Generation Control 11	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error in the ATCM (error source 11). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b11	ECMNMIE011	ECM Non-maskable Interrupt Generation Control 12	Enables or disables a non-maskable interrupt due to occurrence of a 2-bit ECC error in the ATCM (error source 12). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b12	ECMNMIE012	ECM Non-maskable Interrupt Generation Control 13	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error in the BTCM (error source 13). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b13	ECMNMIE013	ECM Non-maskable Interrupt Generation Control 14	Enables or disables a non-maskable interrupt due to occurrence of a 2-bit ECC error in the BTCM (error source 14). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b14	ECMNMIE014	ECM Non-maskable Interrupt Generation Control 15	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error in the IRAM or DRAM (error source 15). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b15	ECMNMIE015	ECM Non-maskable Interrupt Generation Control 16	Enables or disables a non-maskable interrupt due to occurrence of a 2-bit ECC error in the IRAM or DRAM (error source 16). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b16	ECMNMIE016	ECM Non-maskable Interrupt Generation Control 17	Enables or disables a non-maskable interrupt due to occurrence of a 1-bit ECC error in the RSCAN RAM (error source 17). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b17	ECMNMIE017	ECM Non-maskable Interrupt Generation Control 18	Enables or disables a non-maskable interrupt due to occurrence of a 2-bit ECC error in the RSCAN RAM (error source 18). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b18	ECMNMIE018	ECM Non-maskable Interrupt Generation Control 19	Enables or disables a non-maskable interrupt due to occurrence of an RSCAN overflow error (error source 19). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b19	ECMNMIE019	ECM Non-maskable Interrupt Generation Control 20	Enables or disables a non-maskable interrupt due to occurrence of an error of main clock oscillation stop detection (error source 20). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	ECMNMIE020	ECM Non-maskable Interrupt Generation Control 21	Enables or disables a non-maskable interrupt due to occurrence of an error of CLMA0 oscillation stop detection (PLL0) (error source 21). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b21	ECMNMIE021	ECM Non-maskable Interrupt Generation Control 22	Enables or disables a non-maskable interrupt due to occurrence of an error of CLMA1 oscillation stop detection (PLL1) (error source 22). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b22	ECMNMIE022	ECM Non-maskable Interrupt Generation Control 23	Enables or disables a non-maskable interrupt due to occurrence of an error of CLMA2 oscillation stop detection (LOCO) (error source 23). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b23	ECMNMIE023	ECM Non-maskable Interrupt Generation Control 24	Enables or disables a non-maskable interrupt due to occurrence of a 12-bit A/D converter unit 0 overwrite interrupt (error source 24). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b24	ECMNMIE024	ECM Non-maskable Interrupt Generation Control 25	Enables or disables a non-maskable interrupt due to occurrence of a 12-bit A/D converter unit 1 overwrite interrupt (error source 25). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b25	ECMNMIE025	ECM Non-maskable Interrupt Generation Control 26	Enables or disables a non-maskable interrupt due to occurrence of a UVW overcurrent abnormality detection error (error source 26). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b26	ECMNMIE026	ECM Non-maskable Interrupt Generation Control 27	Enables or disables a non-maskable interrupt due to occurrence of a UVW total current abnormality detection error (error source 27). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b27	ECMNMIE027	ECM Non-maskable Interrupt Generation Control 28	Enables or disables a non-maskable interrupt due to occurrence of a UVW short circuit abnormality detection error (error source 28). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b28	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b29	ECMNMIE029	ECM Non-maskable Interrupt Generation Control 30	Enables or disables a non-maskable interrupt due to occurrence of an X overcurrent abnormality detection error (error source 30). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b30	ECMNMIE030	ECM Non-maskable Interrupt Generation Control 31	Enables or disables a non-maskable interrupt due to occurrence of an X short circuit abnormality detection error (error source 31). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W
b31	ECMNMIE031	ECM Non-maskable Interrupt Generation Control 32	Enables or disables a non-maskable interrupt due to occurrence of a DOC operation error (error source 32). 0: Interrupt generation disabled 1: Interrupt generation enabled	R/W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.12 ECM Non-maskable Interrupt Configuration Register 1 (ECMNMICFG1)

The ECMNMICFG1 register controls generation of ECM non-maskable interrupts due to occurrence of individual error sources.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b1	ECMIRE001	ECM Internal Reset Generation Control 2	Enables or disables generation of an ECM reset due to occurrence of a WDT overflow/refresh error (for Cortex-M3) (error source 2).*1 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b2	ECMIRE002	ECM Internal Reset Generation Control 3	Enables or disables generation of an ECM reset due to occurrence of an IWDTa overflow/refresh error (error source 3). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ECMIRE004	ECM Internal Reset Generation Control 5	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error (with correction) or a 2-bit ECC error (without correction) in the instruction cache (Tag RAM) (error source 5). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b5	ECMIRE005	ECM Internal Reset Generation Control 6	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error (with correction) or a 2-bit ECC error (without correction) in the instruction cache (Data RAM) (error source 6). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b6	ECMIRE006	ECM Internal Reset Generation Control 7	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error in the data cache (Tag/Dirty RAM) (error source 7). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b7	ECMIRE007	ECM Internal Reset Generation Control 8	Enables or disables generation of an ECM reset due to occurrence of a 2-bit ECC error in the data cache (Tag/Dirty RAM) (error source 8). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b8	ECMIRE008	ECM Internal Reset Generation Control 9	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error in the data cache (Data RAM) (error source 9). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b9	ECMIRE009	ECM Internal Reset Generation Control 10	Enables or disables generation of an ECM reset due to occurrence of a 2-bit ECC error in the data cache (Data RAM) (error source 10). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b10	ECMIRE010	ECM Internal Reset Generation Control 11	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error in the ATCM (error source 11). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b11	ECMIRE011	ECM Internal Reset Generation Control 12	Enables or disables generation of an ECM reset due to occurrence of a 2-bit ECC error in the ATCM (error source 12). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b12	ECMIRE012	ECM Internal Reset Generation Control 13	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error in the BTCM (error source 13). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b13	ECMIRE013	ECM Internal Reset Generation Control 14	Enables or disables generation of an ECM reset due to occurrence of a 2-bit ECC error in the BTCM (error source 14). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b14	ECMIRE014	ECM Internal Reset Generation Control 15	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error in the IRAM or DRAM (error source 15). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b15	ECMIRE015	ECM Internal Reset Generation Control 16	Enables or disables generation of an ECM reset due to occurrence of a 2-bit ECC error in the IRAM or DRAM (error source 16). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b16	ECMIRE016	ECM Internal Reset Generation Control 17	Enables or disables generation of an ECM reset due to occurrence of a 1-bit ECC error in the RSCAN RAM (error source 17). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b17	ECMIRE017	ECM Internal Reset Generation Control 18	Enables or disables generation of an ECM reset due to occurrence of a 2-bit ECC error in the RSCAN RAM (error source 18). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b18	ECMIRE018	ECM Internal Reset Generation Control 19	Enables or disables generation of an ECM reset due to occurrence of an RSCAN overflow error (error source 19). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b19	ECMIRE019	ECM Internal Reset Generation Control 20	Enables or disables generation of an ECM reset due to occurrence of an error of main clock oscillation stop detection (error source 20). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	ECMIRE020	ECM Internal Reset Generation Control 21	Enables or disables generation of an ECM reset due to occurrence of an error of CLMA0 oscillation stop detection (PLL0) (error source 21). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b21	ECMIRE021	ECM Internal Reset Generation Control 22	Enables or disables generation of an ECM reset due to occurrence of an error of CLMA1 oscillation stop detection (PLL1) (error source 22). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b22	ECMIRE022	ECM Internal Reset Generation Control 23	Enables or disables generation of an ECM reset due to occurrence of an error of CLMA2 oscillation stop detection (LOCO) (error source 23). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b23	ECMIRE023	ECM Internal Reset Generation Control 24	Enables or disables generation of an ECM reset due to occurrence of a 12-bit A/D converter unit 0 overwrite interrupt (error source 24). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b24	ECMIRE024	ECM Internal Reset Generation Control 25	Enables or disables generation of an ECM reset due to occurrence of a 12-bit A/D converter unit 1 overwrite interrupt (error source 25). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b25	ECMIRE025	ECM Internal Reset Generation Control 26	Enables or disables generation of an ECM reset due to occurrence of a UVW overcurrent abnormality detection error (error source 26). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b26	ECMIRE026	ECM Internal Reset Generation Control 27	Enables or disables generation of an ECM reset due to occurrence of a UVW total current abnormality detection error (error source 27). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b27	ECMIRE027	ECM Internal Reset Generation Control 28	Enables or disables generation of an ECM reset due to occurrence of a UVW short circuit abnormality detection error (error source 28). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b28	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b29	ECMIRE029	ECM Internal Reset Generation Control 30	Enables or disables generation of an ECM reset due to occurrence of an X overcurrent abnormality detection error (error source 30). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b30	ECMIRE030	ECM Internal Reset Generation Control 31	Enables or disables generation of an ECM reset due to occurrence of an X short circuit abnormality detection error (error source 31). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b31	ECMIRE031	ECM Internal Reset Generation Control 32	Enables or disables generation of an ECM reset due to occurrence of a DOC operation error (error source 32). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.15 ECM Internal Reset Configuration Register 1 (ECMIRCFG1)

The ECMIRCFG1 register controls generation of internal resets (ECM resets) due to occurrence of individual error sources.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b31 to b9	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.2.16 ECM Internal Reset Configuration Register 2 (ECMIRCFG2)

The ECMIRCFG2 register controls generation of internal resets (ECM resets) due to occurrence of individual error sources.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D0A4h

b28	ECMIRE228	ECM Internal Reset Generation Control 93	Enables or disables generation of an ECM reset due to occurrence of an ECM compare error (error source 93). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b29	ECMIRE229	ECM Internal Reset Generation Control 94	Enables or disables generation of an ECM reset due to occurrence of a delay timer overflow (error source 94). 0: ECM reset generation disabled 1: ECM reset generation enabled	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.2.17 ECM Error Mask Register 0 (ECMEMK0)

The ECMEMK0 register controls mask settings for error output signals due to occurrence of individual error sources. If an unmasked error output signal is generated, the output of the ERROROUT# pin is set to the active level (low level). This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Bit	Symbol	Bit Name	Description	R/W
b0	ECMEMK000	ECM Error Output Signal Mask Control 1	Controls whether to mask an error output signal due to occurrence of a WDT overflow/refresh error (for Cortex-R4) (error source 1). 0: Error signal output not masked 1: Error signal output masked	R/W
b1	ECMEMK001	ECM Error Output Signal Mask Control 2	Controls whether to mask an error output signal due to occurrence of a WDT overflow/refresh error (for Cortex-M3) (error source 2).*1 0: Error signal output not masked 1: Error signal output masked	R/W
b2	ECMEMK002	ECM Error Output Signal Mask Control 3	Controls whether to mask an error output signal due to occurrence of an IWDTa overflow/refresh error (error source 3). 0: Error signal output not masked 1: Error signal output masked	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	ECMEMK004	ECM Error Output Signal Mask Control 5	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error (with correction) or a 2-bit ECC error (without correction) in the instruction cache (Tag RAM) (error source 5). 0: Error signal output not masked 1: Error signal output masked	R/W
b5	ECMEMK005	ECM Error Output Signal Mask Control 6	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error (with correction) or a 2-bit ECC error (without correction) in the instruction cache (Data RAM) (error source 6). 0: Error signal output not masked 1: Error signal output masked	R/W
b6	ECMEMK006	ECM Error Output Signal Mask Control 7	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error in the data cache (Tag/Dirty RAM) (error source 7). 0: Error signal output not masked 1: Error signal output masked	R/W
b7	ECMEMK007	ECM Error Output Signal Mask Control 8	Controls whether to mask an error output signal due to occurrence of a 2-bit ECC error in the data cache (Tag/Dirty RAM) (error source 8). 0: Error signal output not masked 1: Error signal output masked	R/W

Bit	Symbol	Bit Name	Description	R/W
b8	ECMEMK008	ECM Error Output Signal Mask Control 9	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error in the data cache (Data RAM) (error source 9). 0: Error signal output not masked 1: Error signal output masked	R/W
b9	ECMEMK009	ECM Error Output Signal Mask Control 10	Controls whether to mask an error output signal due to occurrence of a 2-bit ECC error in the data cache (Data RAM) (error source 10). 0: Error signal output not masked 1: Error signal output masked	R/W
b10	ECMEMK010	ECM Error Output Signal Mask Control 11	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error in the ATCM (error source 11). 0: Error signal output not masked 1: Error signal output masked	R/W
b11	ECMEMK011	ECM Error Output Signal Mask Control 12	Controls whether to mask an error output signal due to occurrence of a 2-bit ECC error in the ATCM (error source 12). 0: Error signal output not masked 1: Error signal output masked	R/W
b12	ECMEMK012	ECM Error Output Signal Mask Control 13	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error in the BTCM (error source 13). 0: Error signal output not masked 1: Error signal output masked	R/W
b13	ECMEMK013	ECM Error Output Signal Mask Control 14	Controls whether to mask an error output signal due to occurrence of a 2-bit ECC error in the BTCM (error source 14). 0: Error signal output not masked 1: Error signal output masked	R/W
b14	ECMEMK014	ECM Error Output Signal Mask Control 15	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error in the IRAM or DRAM (error source 15). 0: Error signal output not masked 1: Error signal output masked	R/W
b15	ECMEMK015	ECM Error Output Signal Mask Control 16	Controls whether to mask an error output signal due to occurrence of a 2-bit ECC error in the IRAM or DRAM (error source 16). 0: Error signal output not masked 1: Error signal output masked	R/W
b16	ECMEMK016	ECM Error Output Signal Mask Control 17	Controls whether to mask an error output signal due to occurrence of a 1-bit ECC error in the RSCAN RAM (error source 17). 0: Error signal output not masked 1: Error signal output masked	R/W
b17	ECMEMK017	ECM Error Output Signal Mask Control 18	Controls whether to mask an error output signal due to occurrence of a 2-bit ECC error in the RSCAN RAM (error source 18). 0: Error signal output not masked 1: Error signal output masked	R/W
b18	ECMEMK018	ECM Error Output Signal Mask Control 19	Controls whether to mask an error output signal due to occurrence of an RSCAN overflow error (error source 19). 0: Error signal output not masked 1: Error signal output masked	R/W
b19	ECMEMK019	ECM Error Output Signal Mask Control 20	Controls whether to mask an error output signal due to occurrence of an error of main clock oscillation stop detection (error source 20). 0: Error signal output not masked 1: Error signal output masked	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	ECMEMK020	ECM Error Output Signal Mask Control 21	Controls whether to mask an error output signal due to occurrence of an error of CLMA0 oscillation stop detection (PLL0) (error source 21). 0: Error signal output not masked 1: Error signal output masked	R/W
b21	ECMEMK021	ECM Error Output Signal Mask Control 22	Controls whether to mask an error output signal due to occurrence of an error of CLMA1 oscillation stop detection (PLL1) (error source 22). 0: Error signal output not masked 1: Error signal output masked	R/W
b22	ECMEMK022	ECM Error Output Signal Mask Control 23	Controls whether to mask an error output signal due to occurrence of an error of CLMA2 oscillation stop detection (LOCO) (error source 23). 0: Error signal output not masked 1: Error signal output masked	R/W
b23	ECMEMK023	ECM Error Output Signal Mask Control 24	Controls whether to mask an error output signal due to occurrence of a 12-bit A/D converter unit 0 overwrite interrupt (error source 24). 0: Error signal output not masked 1: Error signal output masked	R/W
b24	ECMEMK024	ECM Error Output Signal Mask Control 25	Controls whether to mask an error output signal due to occurrence of a 12-bit A/D converter unit 1 overwrite interrupt (error source 25). 0: Error signal output not masked 1: Error signal output masked	R/W
b25	ECMEMK025	ECM Error Output Signal Mask Control 26	Controls whether to mask an error output signal due to occurrence of a UVW overcurrent abnormality detection error (error source 26). 0: Error signal output not masked 1: Error signal output masked	R/W
b26	ECMEMK026	ECM Error Output Signal Mask Control 27	Controls whether to mask an error output signal due to occurrence of a UVW total current abnormality detection error (error source 27). 0: Error signal output not masked 1: Error signal output masked	R/W
b27	ECMEMK027	ECM Error Output Signal Mask Control 28	Controls whether to mask an error output signal due to occurrence of a UVW short circuit abnormality detection error (error source 28). 0: Error signal output not masked 1: Error signal output masked	R/W
b28	ECMEMK028	ECM Error Output Signal Mask Control 29	Always write 1.	R/W
b29	ECMEMK029	ECM Error Output Signal Mask Control 30	Controls whether to mask an error output signal due to occurrence of an X overcurrent abnormality detection error (error source 30). 0: Error signal output not masked 1: Error signal output masked	R/W
b30	ECMEMK030	ECM Error Output Signal Mask Control 31	Controls whether to mask an error output signal due to occurrence of an X short circuit abnormality detection error (error source 31). 0: Error signal output not masked 1: Error signal output masked	R/W
b31	ECMEMK031	ECM Error Output Signal Mask Control 32	Controls whether to mask an error output signal due to occurrence of a DOC operation error (error source 32). 0: Error signal output not masked 1: Error signal output masked	R/W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.18 ECM Error Mask Register 1 (ECMEMK1)

The ECMEMK1 register controls mask settings for error output signals due to occurrence of individual error sources. If an unmasked error output signal is generated, the output of the ERROROUT# pin is set to the active level (low level). This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b28	ECMEMK228	ECM Internal Reset Generation Control 93	ECM Error Output Signal Mask Control Controls whether to mask an error output signal due to occurrence of an ECM compare error (error source 93). 0: Error signal output not masked 1: Error signal output masked	R/W
b29	ECMEMK229	ECM Internal Reset Generation Control 94	ECM Error Output Signal Mask Control Controls whether to mask an error output signal due to occurrence of a delay timer overflow (error source 94). 0: Error signal output not masked 1: Error signal output masked	R/W
b31, b30	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.2.20 ECM Error Source Status Clear Trigger Register 0 (ECMESSTC0)

The ECMESSTC0 register controls clearing of individual error statuses. Setting individual bits in this register to 1 can clear the corresponding error statuses held in the ECMmESSTR0 (m = M or C) register.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Bit	Symbol	Bit Name	Description	R/W
b0	ECMCLSSE000	ECM Error Status Clear 1	Clears the error status of WDT overflow/refresh error (for Cortex-R4) (error source 1) and the ECMmESSTR0.ECMmSSE000 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b1	ECMCLSSE001	ECM Error Status Clear 2	Clears the error status of WDT overflow/refresh error (for Cortex-M3) (error source 2) and the ECMmESSTR0.ECMmSSE001 bit.*1 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b2	ECMCLSSE002	ECM Error Status Clear 3	Clears the error status of IWDTa overflow/refresh error (error source 3) and the ECMmESSTR0.ECMmSSE002 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b3	—	Reserved	The write value should be 0.	W
b4	ECMCLSSE004	ECM Error Status Clear 5	Clears the error status of a 1-bit ECC error (with correction) or a 2-bit ECC error (without correction) in the instruction cache (Tag RAM) (error source 5) and the ECMmESSTR0.ECMmSSE004 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b5	ECMCLSSE005	ECM Error Status Clear 6	Clears the error status of a 1-bit ECC error (with correction) or a 2-bit ECC error (without correction) in the instruction cache (Data RAM) (error source 6) and the ECMmESSTR0.ECMmSSE005 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b6	ECMCLSSE006	ECM Error Status Clear 7	Clears the error status of 1-bit ECC error in the data cache (Tag/Dirty RAM) (error source 7) and the ECMmESSTR0.ECMmSSE006 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b7	ECMCLSSE007	ECM Error Status Clear 8	Clears the error status of 2-bit ECC error in the data cache (Tag/Dirty RAM) (error source 8) and the ECMmESSTR0.ECMmSSE007 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W

Bit	Symbol	Bit Name	Description	R/W
b8	ECMCLSSE008	ECM Error Status Clear 9	Clears the error status of 1-bit ECC error in the data cache (Data RAM) (error source 9) and the ECMmESSTR0.ECMmSSE008 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b9	ECMCLSSE009	ECM Error Status Clear 10	Clears the error status of 2-bit ECC error in the data cache (Data RAM) (error source 10) and the ECMmESSTR0.ECMmSSE009 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b10	ECMCLSSE010	ECM Error Status Clear 11	Clears the error status of 1-bit ECC error in the ATCM (error source 11) and the ECMmESSTR0.ECMmSSE010 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b11	ECMCLSSE011	ECM Error Status Clear 12	Clears the error status of 2-bit ECC error in the ATCM (error source 12) and the ECMmESSTR0.ECMmSSE011 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b12	ECMCLSSE012	ECM Error Status Clear 13	Clears the error status of 1-bit ECC error in the BTCM (error source 13) and the ECMmESSTR0.ECMmSSE012 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b13	ECMCLSSE013	ECM Error Status Clear 14	Clears the error status of 2-bit ECC error in the BTCM (error source 14) and the ECMmESSTR0.ECMmSSE013 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b14	ECMCLSSE014	ECM Error Status Clear 15	Clears the error status of 1-bit ECC error in the IRAM or DRAM (error source 15) and the ECMmESSTR0.ECMmSSE014 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b15	ECMCLSSE015	ECM Error Status Clear 16	Clears the error status of 2-bit ECC error in the IRAM or DRAM (error source 16) and the ECMmESSTR0.ECMmSSE015 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b16	ECMCLSSE016	ECM Error Status Clear 17	Clears the error status of 1-bit ECC error in the RSCAN RAM (error source 17) and the ECMmESSTR0.ECMmSSE016 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b17	ECMCLSSE017	ECM Error Status Clear 18	Clears the error status of 2-bit ECC error in the RSCAN RAM (error source 18) and the ECMmESSTR0.ECMmSSE017 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b18	ECMCLSSE018	ECM Error Status Clear 19	Clears the error status of RSCAN overflow error (error source 19) and the ECMmESSTR0.ECMmSSE018 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b19	ECMCLSSE019	ECM Error Status Clear 20	Clears the error status of main clock oscillation stop detection (error source 20) and the ECMmESSTR0.ECMmSSE019 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W

Bit	Symbol	Bit Name	Description	R/W
b20	ECMCLSSE020	ECM Error Status Clear 21	Clears the error status of CLMA0 oscillation stop detection (PLL0) (error source 21) and the ECMmESSTR0.ECMmSSE020 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b21	ECMCLSSE021	ECM Error Status Clear 22	Clears the error status of CLMA1 oscillation stop detection (PLL1) (error source 22) and the ECMmESSTR0.ECMmSSE021 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b22	ECMCLSSE022	ECM Error Status Clear 23	Clears the error status of CLMA2 oscillation stop detection (LOCO) (error source 23) and the ECMmESSTR0.ECMmSSE022 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b23	ECMCLSSE023	ECM Error Status Clear 24	Clears the error status of a 12-bit A/D converter unit 0 overwrite interrupt (error source 24) and the ECMmESSTR0.ECMmSSE023 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b24	ECMCLSSE024	ECM Error Status Clear 25	Clears the error status of a 12-bit A/D converter unit 1 overwrite interrupt (error source 25) and the ECMmESSTR0.ECMmSSE024 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b25	ECMCLSSE025	ECM Error Status Clear 26	Clears the error status of UVW overcurrent abnormality detection error (error source 26) and the ECMmESSTR0.ECMmSSE025 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b26	ECMCLSSE026	ECM Error Status Clear 27	Clears the error status of UVW total current abnormality detection error (error source 27) and the ECMmESSTR0.ECMmSSE026 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b27	ECMCLSSE027	ECM Error Status Clear 28	Clears the error status of UVW short circuit abnormality detection error (error source 28) and the ECMmESSTR0.ECMmSSE027 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b28	—	Reserved	The write value should be 0.	W
b29	ECMCLSSE029	ECM Error Status Clear 30	Clears the error status of X overcurrent abnormality detection error (error source 30) and the ECMmESSTR0.ECMmSSE029 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b30	ECMCLSSE030	ECM Error Status Clear 31	Clears the error status of X short circuit abnormality detection error (error source 31) and the ECMmESSTR0.ECMmSSE030 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W
b31	ECMCLSSE031	ECM Error Status Clear 32	Clears the error status of DOC operation error (error source 32) and the ECMmESSTR0.ECMmSSE031 bit. 0: Corresponding error status unchanged 1: Corresponding error status cleared	W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.21 ECM Error Source Status Clear Trigger Register 1 (ECMESSTC1)

The ECMESSTC1 register controls clearing of individual error statuses. Setting individual bits in this register to 1 can clear the corresponding error statuses held in the ECMmESSTR1 (m = M or C) register.

This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.

Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D0B8h

Bit	Symbol	Bit Name	Description	R/W
b31 to b9	—	Reserved	The write value should be 0.	W

42.2.22 ECM Error Source Status Clear Trigger Register 2 (ECMESSTC2)

The ECMESSTC2 register controls clearing of individual error statuses. Setting individual bits in this register to 1 can clear the corresponding error statuses held in the ECMmESSTR2 (m = M or C) register.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b0	ECMPRERR	ECM Protection Status	Indicates whether writing to the write protected register has been correctly done. 0: Writing was successful. 1: Writing failed.	R
b7 to b1	—	Reserved	These bits are read as 0.	R

42.2.25 ECM Pseudo Error Trigger Register 0 (ECMPE0)

The ECMPE0 register is a control register that issues a pseudo error for self-diagnosis. When a pseudo error is issued, an interrupt set by ECM or an ECM reset occurs in the same way as when an actual error source occurs.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D0C8h

Bit	Symbol	Bit Name	Description	R/W
b0	ECMPE000	ECM Pseudo Error Trigger 1	Generates a pseudo WDT overflow/refresh error (for Cortex-R4) (error source 1). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b1	ECMPE001	ECM Pseudo Error Trigger 2	Generates a pseudo WDT overflow/refresh error (for Cortex-M3) (error source 2).*1 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b2	ECMPE002	ECM Pseudo Error Trigger 3	Generates a pseudo IWDTa overflow/refresh error (error source 3). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b3	—	Reserved	The write value should be 0.	W
b4	ECMPE004	ECM Pseudo Error Trigger 5	Generates a pseudo 1-bit ECC error (with correction) or 2-bit ECC error (without correction) in the instruction cache (Tag RAM) (error source 5). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b5	ECMPE005	ECM Pseudo Error Trigger 6	Generates a pseudo 1-bit ECC error (with correction) or 2-bit ECC error (without correction) in the instruction cache (Data RAM) (error source 6). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b6	ECMPE006	ECM Pseudo Error Trigger 7	Generates a pseudo 1-bit ECC error in the data cache (Tag/Dirty RAM) (error source 7). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b7	ECMPE007	ECM Pseudo Error Trigger 8	Generates a pseudo 2-bit ECC error in the data cache (Tag/Dirty RAM) (error source 8). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b8	ECMPE008	ECM Pseudo Error Trigger 9	Generates a pseudo 1-bit ECC error in the data cache (Data RAM) (error source 9). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W

Bit	Symbol	Bit Name	Description	R/W
b9	ECMPE009	ECM Pseudo Error Trigger 10	Generates a pseudo 2-bit ECC error in the data cache (Data RAM) (error source 10). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b10	ECMPE010	ECM Pseudo Error Trigger 11	Generates a pseudo 1-bit ECC error in the ATCM (error source 11). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b11	ECMPE011	ECM Pseudo Error Trigger 12	Generates a pseudo 2-bit ECC error in the ATCM (error source 12). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b12	ECMPE012	ECM Pseudo Error Trigger 13	Generates a pseudo 1-bit ECC error in the BTCM (error source 13). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b13	ECMPE013	ECM Pseudo Error Trigger 14	Generates a pseudo 2-bit ECC error in the BTCM (error source 14). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b14	ECMPE014	ECM Pseudo Error Trigger 15	Generates a pseudo 1-bit ECC error in the IRAM or DRAM (error source 15). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b15	ECMPE015	ECM Pseudo Error Trigger 16	Generates a pseudo 2-bit ECC error in the IRAM or DRAM (error source 16). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b16	ECMPE016	ECM Pseudo Error Trigger 17	Generates a pseudo 1-bit ECC error in the RSCAN RAM (error source 17). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b17	ECMPE017	ECM Pseudo Error Trigger 18	Generates a pseudo 2-bit ECC error in the RSCAN RAM (error source 18). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b18	ECMPE018	ECM Pseudo Error Trigger 19	Generates a pseudo RSCAN overflow error (error source 19). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b19	ECMPE019	ECM Pseudo Error Trigger 20	Generates pseudo detection of main clock oscillation stoppage (error source 20). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b20	ECMPE020	ECM Pseudo Error Trigger 21	Generates pseudo detection of CLMA0 oscillation stoppage (PLL0) (error source 21). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b21	ECMPE021	ECM Pseudo Error Trigger 22	Generates pseudo detection of CLMA1 oscillation stoppage (PLL1) (error source 22). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b22	ECMPE022	ECM Pseudo Error Trigger 23	Generates pseudo detection of CLMA2 oscillation stoppage (LOCO) (error source 23). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b23	ECMPE023	ECM Pseudo Error Trigger 24	Generates a pseudo 12-bit A/D converter unit 0 overwrite interrupt (error source 24). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W

Bit	Symbol	Bit Name	Description	R/W
b24	ECMPE024	ECM Pseudo Error Trigger 25	Generates a pseudo 12-bit A/D converter unit 1 overwrite interrupt (error source 25). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b25	ECMPE025	ECM Pseudo Error Trigger 26	Generates a pseudo UVW overcurrent abnormality detection error (error source 26). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b26	ECMPE026	ECM Pseudo Error Trigger 27	Generates a pseudo UVW total current abnormality detection error (error source 27). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b27	ECMPE027	ECM Pseudo Error Trigger 28	Generates a pseudo UVW short circuit abnormality detection error (error source 28). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b28	—	Reserved	The write value should be 0.	W
b29	ECMPE029	ECM Pseudo Error Trigger 30	Generates a pseudo X overcurrent abnormality detection error (error source 30). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b30	ECMPE030	ECM Pseudo Error Trigger 31	Generates a pseudo X short circuit abnormality detection error (error source 31). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b31	ECMPE031	ECM Pseudo Error Trigger 32	Generates a pseudo DOC operation error (error source 32). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.26 ECM Pseudo Error Trigger Register 1 (ECMPE1)

The ECMPE1 register is a control register that issues a pseudo error for self-diagnosis. When a pseudo error is issued, an interrupt set by ECM or an ECM reset occurs in the same way as when an actual error source occurs.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.
Bits 2 to 8 are trigger bits for extended pseudo errors. For details, see section 42.3.3, Pseudo Error Generation.

b0	ECMPE100	ECM Pseudo Error Trigger 33	Generates a pseudo bus error (error source 33). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b1	ECMPE101	ECM Pseudo Error Trigger 34	Generates a pseudo timeout error caused by the external WAIT pin (error source 34). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b2	ECMPE102	ECM Pseudo Error Trigger 35	Generates a pseudo “extended pseudo error 35” (error source 35). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b3	ECMPE103	ECM Pseudo Error Trigger 36	Generates a pseudo “extended pseudo error 36” (error source 36). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b4	ECMPE104	ECM Pseudo Error Trigger 37	Generates a pseudo “extended pseudo error 37” (error source 37). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b5	ECMPE105	ECM Pseudo Error Trigger 38	Generates a pseudo “extended pseudo error 38” (error source 38). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b6	ECMPE106	ECM Pseudo Error Trigger 39	Generates a pseudo “extended pseudo error 39” (error source 39). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b7	ECMPE107	ECM Pseudo Error Trigger 40	Generates a pseudo “extended pseudo error 40” (error source 40). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b8	ECMPE108	ECM Pseudo Error Trigger 41	Generates a pseudo “extended pseudo error 41” (error source 41). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b31 to b9	—	Reserved	The write value should be 0.	W

42.2.27 ECM Pseudo Error Trigger Register 2 (ECMPE2)

The ECMPE2 register is a control register that issues a pseudo error for self-diagnosis. When a pseudo error is issued, an interrupt set by ECM or an ECM reset occurs in the same way as when an actual error source occurs.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D0D0h

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b27 to b0	—	Reserved	The write value should be 0.	W
b28	ECMPE228	ECM Pseudo Error Trigger 93	Generates a pseudo EMC error (error source 93). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b29	ECMPE229	ECM Pseudo Error Trigger 94	Generates a pseudo delay timer overflow (error source 94). 0: Pseudo error not generated 1: Generates corresponding pseudo error	W
b31, b30	—	Reserved	The write value should be 0.	W

42.2.28 ECM Delay Timer Control Register (ECMDTMCTL)

The ECMDTMCTL register controls the delay timer.
This register is a common register. Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D0D4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	DTMSTACNTCLK	—	—	DTMSTP	DTMSTA
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DTMSTA	Delay Timer Start	Sets the operation of the delay timer. 0: Delay timer operation disabled 1: Delay timer operation enabled	R/W
b1	DTMSTP	Delay Timer Stop	Writing 1 to this bit initializes the delay timer counter, causing the delay timer to stop. Simultaneously, the DTMSTA bit is set to 0.	W
b3, b2	—	Reserved	These bits are read as 0.	R
b4	DTMSTACNTCLK	Delay Timer Status	The value of the DTMSTA bit is applied to the operating status of the delay timer. If the DTMSTA bit is modified once, modifying the DTMSTA bit is disabled until the setting value of the DTMSTA bit is applied to the DTMSTACNTCLK bit.	R
b7 to b5	—	Reserved	These bits are read as 0.	R

42.2.29 ECM Delay Timer Register (ECMDTMR)

The ECMDTMR register is a 16-bit counter register for the delay timer. The 16-bit counter counts up using ECMCLK (240 kHz). Changing the DTMSTA bit in the ECM delay timer control register from 1 (delay timer operation enabled) to 0 (delay timer operation disabled) initializes the 16-bit counter. This register can only be read.

Address(es): A007 D0D8h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ECMTDMR[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

42.2.30 ECM Delay Timer Compare Register (ECMDTMCMP)

The ECMDTMCMP register is a compare register used to set the overflow cycle of the delay timer. A delay timer overflow signal is generated to set the ECMmSSE229 bit when the value of this register matches with the value of the delay timer counter. Writing data to this register has to be conducted while the delay timer is stopped.
This register is a common register. Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.
Write this register after confirming that the read value of the CMPW bit is 0.

Address(es): A007 D0DCh

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ECMDTMCMP [15:0]	Delay Timer Compare	Sets the overflow cycle of the delay timer. (overflow cycle) = (N + 1) × (ECMCLK cycle (240 kHz)) N: Set value For details, see section 42.3.5, Timeout Function for Interrupt Processing by Using the Delay Timer.	R/W
b16	CMPW	Compare Write	Indicates whether writing to the delay timer compare bit is enabled. Writing the compare value is possible when this bit is 0. 0: Writing to ECMDTMCMP[15:0] enabled 1: Writing to ECMDTMCMP[15:0] disabled	R
b31 to b17	—	Reserved	These bits are read as 0.	R

42.2.31 ECM Delay Timer Configuration Register 0 (ECMDTMCFG0)

The ECMDTMCFG0 register controls delay timer operation in response to an ECM maskable interrupt. Whether to enable delay timer operation when an ECM maskable interrupt is generated can be set.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b7	ECMTE007	ECM Delay Timer Start Control 8	Enables delay timer operation in response to an ECM maskable interrupt caused by a 2-bit ECC error in the data cache (Tag/Dirty RAM) (error source 8). 0: Delay timer start disabled 1: Delay timer start enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b8	ECMTE008	ECM Delay Timer Start Control 9	Enables delay timer operation in response to an ECM maskable interrupt caused by a 1-bit ECC error in the data cache (Data RAM) (error source 9). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b9	ECMTE009	ECM Delay Timer Start Control 10	Enables delay timer operation in response to an ECM maskable interrupt caused by a 2-bit ECC error in the data cache (Data RAM) (error source 10). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b10	ECMTE010	ECM Delay Timer Start Control 11	Enables delay timer operation in response to an ECM maskable interrupt caused by a 1-bit ECC error in the ATCM (error source 11). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b11	ECMTE011	ECM Delay Timer Start Control 12	Enables delay timer operation in response to an ECM maskable interrupt caused by a 2-bit ECC error in the ATCM (error source 12). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b12	ECMTE012	ECM Delay Timer Start Control 13	Enables delay timer operation in response to an ECM maskable interrupt caused by a 1-bit ECC error in the BTCM (error source 13). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b13	ECMTE013	ECM Delay Timer Start Control 14	Enables delay timer operation in response to an ECM maskable interrupt caused by a 2-bit ECC error in the BTCM (error source 14). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b14	ECMTE014	ECM Delay Timer Start Control 15	Enables delay timer operation in response to an ECM maskable interrupt caused by a 1-bit ECC error in the IRAM or DRAM (error source 15). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b15	ECMTE015	ECM Delay Timer Start Control 16	Enables delay timer operation in response to an ECM maskable interrupt caused by a 2-bit ECC error in the IRAM or DRAM (error source 16). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b16	ECMTE016	ECM Delay Timer Start Control 17	Enables delay timer operation in response to an ECM maskable interrupt caused by a 1-bit ECC error in the RSCAN RAM (error source 17). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b17	ECMTE017	ECM Delay Timer Start Control 18	Enables delay timer operation in response to an ECM maskable interrupt caused by a 2-bit ECC error in the RSCAN RAM (error source 18). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b18	ECMTE018	ECM Delay Timer Start Control 19	Enables delay timer operation in response to an ECM maskable interrupt caused by an RSCAN overflow error (error source 19). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b19	ECMTE019	ECM Delay Timer Start Control 20	Enables delay timer operation in response to an ECM maskable interrupt caused by main clock oscillation stop detection (error source 20). 0: Delay timer start disabled 1: Delay timer start enabled	R/W

Bit	Symbol	Bit Name	Description	R/W
b20	ECMTE020	ECM Delay Timer Start Control 21	Enables delay timer operation in response to an ECM maskable interrupt caused by CLMA0 oscillation stop detection (PLL0) (error source 21). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b21	ECMTE021	ECM Delay Timer Start Control 22	Enables delay timer operation in response to an ECM maskable interrupt caused by CLMA1 oscillation stop detection (PLL1) (error source 22). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b22	ECMTE022	ECM Delay Timer Start Control 23	Enables delay timer operation in response to an ECM maskable interrupt caused by CLMA2 oscillation stop detection (LOCO) (error source 23). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b23	ECMTE023	ECM Delay Timer Start Control 24	Enables delay timer operation in response to an ECM maskable interrupt caused by a 12-bit A/D converter unit 0 overwrite interrupt (error source 24). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b24	ECMTE024	ECM Delay Timer Start Control 25	Enables delay timer operation in response to an ECM maskable interrupt caused by a 12-bit A/D converter unit 1 overwrite interrupt (error source 25). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b25	ECMTE025	ECM Delay Timer Start Control 26	Enables delay timer operation in response to an ECM maskable interrupt caused by a UVW overcurrent abnormality detection error (error source 26). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b26	ECMTE026	ECM Delay Timer Start Control 27	Enables delay timer operation in response to an ECM maskable interrupt caused by a UVW total current abnormality detection error (error source 27). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b27	ECMTE027	ECM Delay Timer Start Control 28	Enables delay timer operation in response to an ECM maskable interrupt caused by a UVW short circuit abnormality detection error (error source 28). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b28	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b29	ECMTE029	ECM Delay Timer Start Control 30	Enables delay timer operation in response to an ECM maskable interrupt caused by an X overcurrent abnormality detection error (error source 30). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b30	ECMTE030	ECM Delay Timer Start Control 31	Enables delay timer operation in response to an ECM maskable interrupt caused by an X short circuit abnormality detection error (error source 31). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b31	ECMTE031	ECM Delay Timer Start Control 32	Enables delay timer operation in response to an ECM maskable interrupt caused by a DOC operation error (error source 32). 0: Delay timer start disabled 1: Delay timer start enabled	R/W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.32 ECM Delay Timer Configuration Register 1 (ECMDTMCFG1)

The ECMDTMCFG1 register controls delay timer operation in response to an ECM maskable interrupt. Whether to enable delay timer operation when an ECM maskable interrupt is generated can be set.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

b27	ECMTE327	ECM Delay Timer Start Control 28	Enables delay timer operation in response to an ECM non-maskable interrupt caused by a UVW short circuit abnormality detection error (error source 28). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b28	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b29	ECMTE329	ECM Delay Timer Start Control 30	Enables delay timer operation in response to an ECM non-maskable interrupt caused by an X overcurrent abnormality detection error (error source 30). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b30	ECMTE330	ECM Delay Timer Start Control 31	Enables delay timer operation in response to an ECM non-maskable interrupt caused by an X short circuit abnormality detection error (error source 31). 0: Delay timer start disabled 1: Delay timer start enabled	R/W
b31	ECMTE331	ECM Delay Timer Start Control 32	Enables delay timer operation in response to an ECM non-maskable interrupt caused by a DOC operation error (error source 32). 0: Delay timer start disabled 1: Delay timer start enabled	R/W

Note 1. This bit is only supported in products incorporating an R-IN engine.
For products other than those incorporating an R-IN engine, do not change the value from the value after a reset.

42.2.35 ECM Delay Timer Configuration Register 4 (ECMDTMCFG4)

The ECMDTMCFG4 register controls delay timer operation in response to an ECM non-maskable interrupt. Whether to enable delay timer operation when an ECM non-maskable interrupt is generated can be set.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

42.2.36 ECM Delay Timer Configuration Register 5 (ECMDTMCFG5)

The ECMDTMCFG5 register controls delay timer operation in response to an ECM non-maskable interrupt. Whether to enable delay timer operation when an ECM non-maskable interrupt is generated can be set.
This register is a common register. Settings for both ECM master and ECM checker can be performed by writing to this register.
Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.

Address(es): A007 D0F4h

b31 to b29	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.2.37 ECM Error Output Clear Disable Configuration Register (ECMEOCCFG)

The ECMEOCCFG register controls the setting to disable clearing of an error output signal.
Clearing an error output signal by the ECMmECLR register (m = M or C) can be disabled until the value of the error output clear disable counter exceeds the value set in this register.
Setting to this register is possible only when no error source occurs.
This register is reset by the RES# pin reset only, and is not reset by other reset sources.
This register is a common register. Writing to this register is protected by the specific instruction sequence. For details, see section 42.3.4, Writing to Protected Registers.
Write this register after confirming that the read value from the CMPW bit is 1.

Address(es): A007 D0F8h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	MSKC	ECM Compare Error Mask for Checker	Masks the ECM compare error source (error source 93) on the ECM checker. 0: ECM compare error not masked 1: ECM compare error masked	R/W
b1	MSKM	ECM Compare Error Mask for Master	Masks the ECM compare error source (error source 93) on the ECM master. 0: ECM compare error not masked 1: ECM compare error masked	R/W
b31 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

42.3 Operations

42.3.1 Operations for Error Output

There are two output modes (non-dynamic and dynamic) for the ERROROUT# pin when an error source occurs.
In non-dynamic mode, the ERROROUT# pin outputs the high level when an error is not detected.
In dynamic mode, the ERROROUT# pin can output a toggle waveform according to the compare match timer W (CMTW) when an error is not detected.
In both modes, the ERROROUT# pin outputs the low level when an error is detected.

Operating Mode	Error Status	ERROROUT# Pin Output Level
Non-dynamic (ECMEPCFG.ECMSL0 bit = 0)	No error*1	High
	Error	Low
Dynamic (ECMEPCFG.ECMSL0 bit = 1)	No error*1	Toggles (according to CMTW input)
	Error	Low

Note 1. After reset is released, the ERROROUT# pin outputs the low level (error status).
Use this pin after clearing the error status according to the procedure described in the note in section 42.2.2.

42.3.1.1 Dynamic Mode Enable

1. Initialize the compare match timer W (CMTW) for the input signal for toggle output. The output compare signal for toggle output can be selected by the ECDMESLR register.
   For details on the CMTW setting, see section 25, Compare Match Timer W (CMTW).
2. Set the output of the ERROROUT# pin to the high level (no error) by setting the ECMmECT bit (m = M or C) of the ECM master/checker error clear trigger register to 1.
3. Set the ECMSL0 bit in the ECM error pulse configuration register (ECMPCFG) to 1 to specify dynamic mode.
4. Start up the CMTW.

42.3.1.2 Dynamic Mode Disable

1. Set the output of the ERROROUT# pin to the low level by setting the ECMmEST bit (m = M or C) in the ECM master/checker error set trigger register to 1.
2. Stop the CMTW operation.
3. Clear the ECMSL0 bit in the ECM error pulse configuration register (ECMPCFG) to 0 to specify non-dynamic mode.

42.3.2 Loop-Back Function

ECM incorporates a loop-back function that is used to check the path for an error output signal from the ECM module to the ERROROUT# pin. The output level of the ERROROUT# pin can be checked with the ECMmSSE231 bit (m = M or C) in the ECM master/checker error source status register 1.

42.3.3 Pseudo Error Generation

ECM can generate individual pseudo error sources for self-diagnosis. ECM generates a pseudo error when the corresponding bit in the ECM pseudo error trigger register (ECMPEn) is set to 1. When a pseudo error is generated, ECM operates in the same way as when a real error occurs, and the settings for error source mask, ECM interrupt, ECM reset, and delay timer all apply in the same way.
Error sources 35 to 41 can be used as extended pseudo errors to detect errors for functional safety as shown below. When software detects an error, it can set a bit in the ECMPEn register to generate a corresponding pseudo error to use a function such as ECM interrupt, ECM reset, or delay timer.

Table 42.3 Example Assignment of Errors for Functional Safety to Error Sources

Error Source Number	Example Functions to be Assigned to Extended Pseudo Errors 35 to 41
35	Access violation to the Cortex-R4 protected area
36	Access violation to the Cortex-M3 protected area (only for products incorporating an R-IN engine)
37	PWM cycle/Duty error
38	ADC unit 0 range over error
39	ADC unit 1 range over error
40	ADC unit 0 pin-level self-diagnosis error
41	ADC unit 1 pin-level self-diagnosis error

42.3.4 Writing to Protected Registers

Write protected registers are protected from incorrect write access due to erroneous program execution, etc.

42.3.4.1 Protection Unlock Sequence

Write access to a write protected register is only possible within the following sequence.

1. Write the fixed value 0000 00A5h to the ECM protection command register (ECMPCMD1) or the ECM master/checker protection command register (ECMmPCMD0) (m = M or C). If the register to be written is the common register, write the fixed value to the ECM protection command register (ECMPCMD1). If the register to be written is not the common register, write the fixed value to the ECM master/checker protection command register (ECMmPCMD0). See descriptions of each register in section 42.2, Registers, to find out whether the target register is a common one or not.
2. Write the desired setting value to the protected, of the ECM common, ECM master, and ECM checker according to the following sequence:
   - Write the desired setting value.
   - Write the inversed value of the desired setting value.
   - Write the desired setting value again.
3. Check the desired setting value has been successfully written to the protected register by checking that the ECMPRERR bit of the ECM protection status register (ECMPS) is 0.

In case of any access to another register between step 1 to step 3 of the above sequence, the protection mechanism behaves as follows.

- If that register belongs to the ECM, the write to the protected register fails (the ECMPRERR bit of the ECM protection status register becomes 1). The sequence has to be reexecuted from step 1.
- If that register does not belong to the ECM, the sequence is not disrupted and the write to the protected register is conducted successfully.

In case the protection unlock sequence is interrupted, the protection mechanism behaves as follows.

- Interrupts during protection sequence
  If an interrupt is acknowledged within the protection sequence and the interrupt process does not access any ECM register, the protection sequence is not disrupted and the write to the protected register can be successfully completed after returning from the interrupt process.

In case a break occurs in the protection unlock sequence, the protection mechanism behaves as follows.

- Breaks during protection sequence
  If the CPU goes into the break state during the protection sequence and any ECM register is not accessed, the protection sequence is not disrupted and the write to the protected register can be successfully completed after returning from the break.
  If the CPU goes into the break state during the protection sequence and any ECM register is accessed, the protection sequence is disrupted and the write to the protected register is not performed after returning from the break.
  Therefore, be careful not to let the CPU go into the break state during the protection sequence.

42.3.5 Timeout Function for Interrupt Processing by Using the Delay Timer

ECM can start the delay timer at the same time as an ECM maskable or non-maskable interrupt request due to occurrence of an error source is issued, to manage timeout of the interrupt processing time. If ECM cannot stop the delay timer (by setting the ECMDTMCTL.DTMSTP bit to 1) during interrupt processing and the count value of the delay timer matches with the value of the delay timer compare register, ECM can generate a delay timer overflow (error source 94), and an error signal output on the ERROROUT# pin or ECM reset. Specify the settings of the error signal output and ECM reset when the delay timer overflow (error source 94) occurs in the ECMEMK2 and ECMIRCFG2 registers, respectively.
The delay timer always starts counting up from 0 by using ECMCLK (240 kHz).
Specify the setting of the overflow cycle of the delay timer in the ECMDTMCMP register.

(Overflow cycle) = (Value set in ECMDTMCMP. ECMDTMCMP[15:0] + 1) × ECMCLK cycle (240 kHz)

Note: The delay timer continues count operation even when a break occurs.

42.3.6 Setting of Disabling Error Output Clear

ECM has a function that disables clearing (by the ECMmECLR register (m = M or C)) of an error signal output from the ERROROUT# pin when an error occurs. An error output signal is disabled during the specified period. This period can be specified in the ECMEOCCFG register.
When an error source occurs, the error output clear disable counter starts counting up by using the ECMCLK clock (240 kHz). Clear processing by the ECMmECLR register for an error output is disabled until the counter value matches with the value set in ECMEOCCFG.ECMEOUTCLRT[15:0]. After the counter value exceeds the set value, clearing of an error output is possible.

(Error output clear disabled period) = (ECMEOUTCLRT[15:0] + 1) × ECMCLK cycle (240 kHz)

If another error source occurs while the error output clear disable counter is in count operation, the counter is cleared and restarts counting up. If the same error source occurs again, the counter is not cleared and continues counting up.

Note: The error output disable counter continues count operation even when a break occurs.

42.4 Usage Notes

42.4.1 Notes Regarding ECMCLK

Counting by the delay timer and by the counter to disable clearing of the error output is of cycles of ECMCKL, a signal generated by the low-speed on-chip oscillator.
After release from the reset state, counting does not proceed or the error output is not cleared if the delay timer is started while the low-speed on-chip oscillator is stopped.
To enable the delay timer function and error output, enable the low-speed on-chip oscillator beforehand and wait for the LOCO oscillation stabilization time.
For details on the low-speed on-chip oscillator, see section 7.2.6, Low-Speed On-Chip Oscillator Control Register (LOCOCR).

43. 12-Bit A/D Converter (S12ADCa)

43.1 Overview

This LSI incorporates two units of a 12-bit successive approximation A/D converter. In unit 0, up to eight analog input channels and temperature sensor output are selectable. In unit 1, up to 16 analog input channels and extended analog input are selectable.

The 12-bit A/D converter converts a maximum of 8 analog input channels and temperature sensor output (unit 0) and a maximum of 16 analog input channels (unit 1), which have been selected, into a 12-bit digital value through successive approximation.

The A/D converter has three operating modes: single scan mode in which the analog inputs of up to 8 (unit 0) and 16 (unit 1) channels arbitrarily selected are converted for only once in ascending channel order; continuous scan mode in which the analog inputs of up to 8 (unit 0) and 16 (unit 1) channels arbitrarily selected are continuously converted in ascending channel order; and group scan mode in which up to 8 (unit 0) and 16 (unit 1) channels of the analog inputs are arbitrarily divided into two groups (group A and group B) and converted in ascending channel order in each group.

In group scan mode, the conditions for scanning start of group A and group B (synchronous trigger) can be independently selected, thus allowing A/D conversion of group A and group B to be started independently. When group A priority control is selected along with operation as described above, if a request to start scanning for group A is received during A/D conversion for group B, the conversion operation for group B is discontinued and the conversion for group A starts, which is given priority.

In double trigger mode, one analog input channel arbitrarily selected is converted in single scan mode or group scan mode (group A), and the resulting data of A/D conversion started by the first and second synchronous triggers are stored into different registers (duplication of A/D conversion data).

The temperature sensor output can be selected at the same time as the analog input of channels. A/D conversion of the analog input of channels and the temperature sensor output is performed in that order.

A/D conversion of the extended analog input is independently performed.

Self-diagnosis, pin-level self-diagnosis, detection of guidewire malfunction, overwrite checking of data registers, and automatic clearing of data registers are provided as security functions.

Table 43.1 lists the specifications of the 12-bit A/D converter and Table 43.2 indicates the functions of the 12-bit A/D converter. Figure 43.1 shows a block diagram of the 12-bit A/D converter (unit 0) and Figure 43.2 shows a block diagram of the 12-bit A/D converter (unit 1).

Table 43.1 Specifications of 12-Bit A/D Converter (1 / 2)

Item	Specifications
Number of units	Two units
Input channels	Unit 0: Up to 8 channels Unit 1: Up to 16 channels + one extended*1
Extended analog function	Temperature sensor output, extended input
A/D conversion method	Successive approximation method
Resolution	12 bits
Conversion time	Unit 0: 0.483 µs per channel (when A/D conversion clock ADCLK = 60 MHz) Unit 1: 0.833 µs per channel*1 (when A/D conversion clock ADCLK = 60 MHz)
A/D conversion clock	Peripheral module clock PCLKH and A/D conversion clock ADCLK (PCLKF or PCLKG)*2 can be set so that the frequency division ratio should be one of the following. PCLKH to ADCLK frequency division ratio = 1:1, 1:2, 1:4, 1:8 ADCLK is set using the clock generation circuit.
Data registers	• 24 registers for analog input (8 for unit 0 and 16 for unit 1), 1 for A/D-converted data duplication in double trigger mode in each unit, and 2 for A/D-converted data duplication during extended operation in double trigger mode in each unit • One register for temperature sensor output (in unit 0 only) • One register for self-diagnosis (per unit) • The results of A/D conversion are stored in 12-bit A/D data registers. • 8-, 10-, and 12-bit accuracy output for the results of A/D conversion • The value obtained by adding up A/D-converted results is stored as a value in the number of bit for conversion accuracy + 2 bits in the A/D data registers in A/D-converted value addition mode. • Double trigger mode (selectable in single scan and group scan modes): The first piece of A/D-converted analog-input data on one selected channel is stored in the data register for the channel, and the second piece is stored in the duplication register. • Extended operation in double trigger mode (available for specific triggers): A/D-converted analog-input data on one selected channel is stored in the duplication register that is prepared for each type of trigger.
Operating modes*3	• Single scan mode: A/D conversion is performed only once on the analog inputs of up to 8 (unit 0) and 16 (unit 1) channels arbitrarily selected and on the temperature sensor output (in unit 0 only). A/D conversion is performed only once on the extended analog input (in unit 1 only). • Continuous scan mode: A/D conversion is performed repeatedly on the analog inputs of up to 8 (unit 0) and 16 (unit 1) channels arbitrarily selected and on the temperature sensor output (in unit 0 only). A/D conversion is performed repeatedly on the extended analog input (in unit 1 only). • Group scan mode: Analog inputs of up to 8 (unit 0) and 16 (unit 1) channels arbitrarily selected and the temperature sensor output (in unit 0 only) are divided into group A and group B, and A/D conversion of the selected analog input is performed only once on a group basis. The conditions for scanning start of group A and group B (synchronous trigger) can be independently selected, thus allowing A/D conversion of group A and group B to be started independently. • Group scan mode (when group A is given priority): If a group A trigger is input during A/D conversion on group B, the A/D conversion on group B is stopped and A/D conversion is performed on group A. Restarting (rescanning) for A/D conversion on group B after completion of A/D conversion on group A can only be set when the ratio between the frequency division settings for PCLKH and ADCLK = 1:1.
Conditions for A/D conversion start	• Software trigger • Synchronous trigger Trigger by the multi-function timer pulse unit (MTU3a), the general-purpose PWM timer (GPTa), the event link controller (ELC), and 16-bit timer pulse unit (TPUa). • Asynchronous trigger A/D conversion can be triggered by the external trigger pins, ADTRG0 (unit 0) and ADTRG1 (unit 1).

Table 43.1 Specifications of 12-Bit A/D Converter (2 / 2)

Item	Specifications
Function	• Sample-and-hold function • Channel-dedicated sample-and-hold function (4ch: in unit 0 only) • Variable sampling state count (which can be set for each channel) • Self-diagnosis of 12-bit A/D converter • Selectable A/D-converted value addition mode or average mode • Analog input disconnection detection function (Precharge function/discharge function) • Double trigger mode (duplication of A/D conversion data) • Switching function of 8-, 10-, and 12-bit conversion*4 • Automatic clear function of A/D data registers • Extended analog input function*3 • Compare Function (which compares the compare register and data register) • Pin-level self-diagnosis function • Overwrite checking function of the A/D data register
Interrupt source	• In the modes except double trigger mode and group scan mode, A/D scan end interrupt (S12ADI) request can be generated on completion of single scan. • In double trigger mode, A/D scan end interrupt (S12ADI) request can be generated on completion of double scan. • In group scan mode, an A/D scan end interrupt (S12ADI) request can be generated on completion of group A scan, whereas an A/D scan end interrupt for group B (S12GBADI) request can be generated on completion of group B scan. • When double trigger mode is selected in group scan mode, A/D scan end interrupt (S12ADI) request can be generated on completion of double scan of group A, whereas A/D scan end interrupt specially for group B (S12GBADI) request can be generated on completion of group B scan. • A compare interrupt (S12CMPI) can be generated in response to the results of detection using compare function. • An AD error interrupt request (S12ADE) can be generated by an error in overwrite checking for data register. • The S12ADI or S12GBADI interrupt can activate the DMA controller (DMAC).
Event link (ELC) function	• An ELC event is generated on completion of scans other than group B scan in group scan mode. • Scan can be started by a trigger output by ELC.
Low-power consumption function	• Module-stop state can be specified.*5

Note 1. One unit for 176-pin devices (only unit 0 is provided)
Note 2. Peripheral module clock PCLKH is fixed to 60 MHz. A/D conversion clock ADCLK is set according to the setting of the SCKCR.PCKF[1:0] bits and the SCKCR.PCKG[1:0] bits in unit 0 and unit 1, respectively.
Note 3. When the extended analog input is selected, do not use group scan mode.
Note 4. When A/D conversion accuracy is modified, A/D conversion time is also changed. See section 43.3.7 Analog Input Sampling and Scan Conversion Time, for details.
Note 5. See section 9, Low-Power Consumption Function, for details.

Table 43.2 Functions of 12-Bit A/D Converter (1 / 2)

Item			Unit 0 (S12ADC0)	Unit 1 (S12ADC1)
Analog input channel			AN000 to AN007 Temperature sensor output	AN100 to AN115 Extended input
Conditions for A/D conversion start	Software	Software trigger	Enabled	Enabled

	Synchronous trigger (trigger from ELC)	ELC trigger	ELCTRG0	ELCTRG1
Channel-dedicated sample-and-hold function	Target channel		AN000 to AN003	—
Interrupt	Interrupt request to the CPU		S12ADI0 S12GBADI0 S12CMPI0 S12ADE0	S12ADI1 S12GBADI1 S12CMPI1 S12ADE1
	Start request to DMAC		S12ADI0 S12GBADI0	S12ADI1 S12GBADI1
	Event output to ELC		S12ADI0	S12ADI1
Setting of module stop function*2, *3			MSTPCRC.MSTPCRC5 bit	MSTPCRC.MSTPCRC4 bit

Note 1. “0” and “1” added to synchronous triggers indicate the number of unit. For the settings to output synchronous triggers, see the sections related to A/D converter startup of the responding modules.
Note 2. See section 9, Low-Power Consumption Function for details.
Note 3. Wait for 1 µs or longer to start A/D conversion after release from the module-stop state.

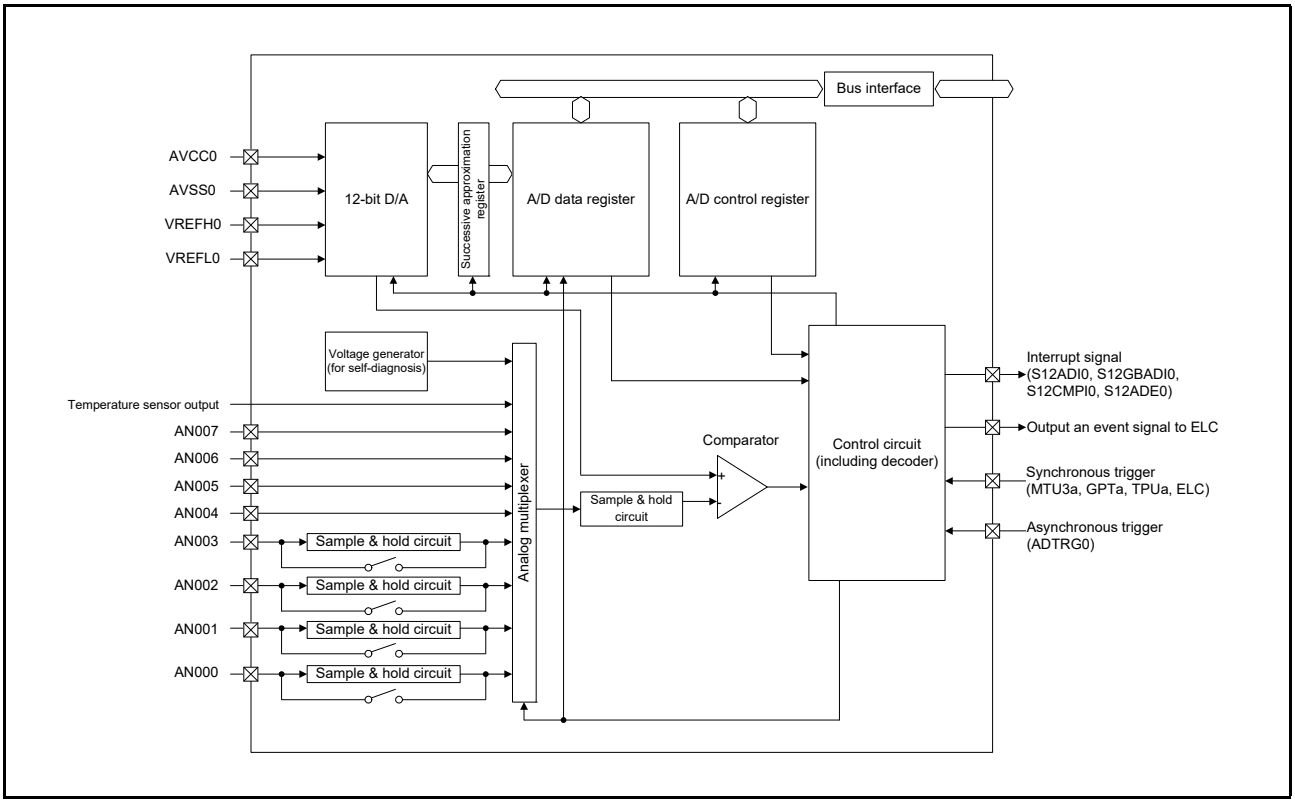

Figure 43.1 Block Diagram of 12-Bit A/D Converter (Unit 0)

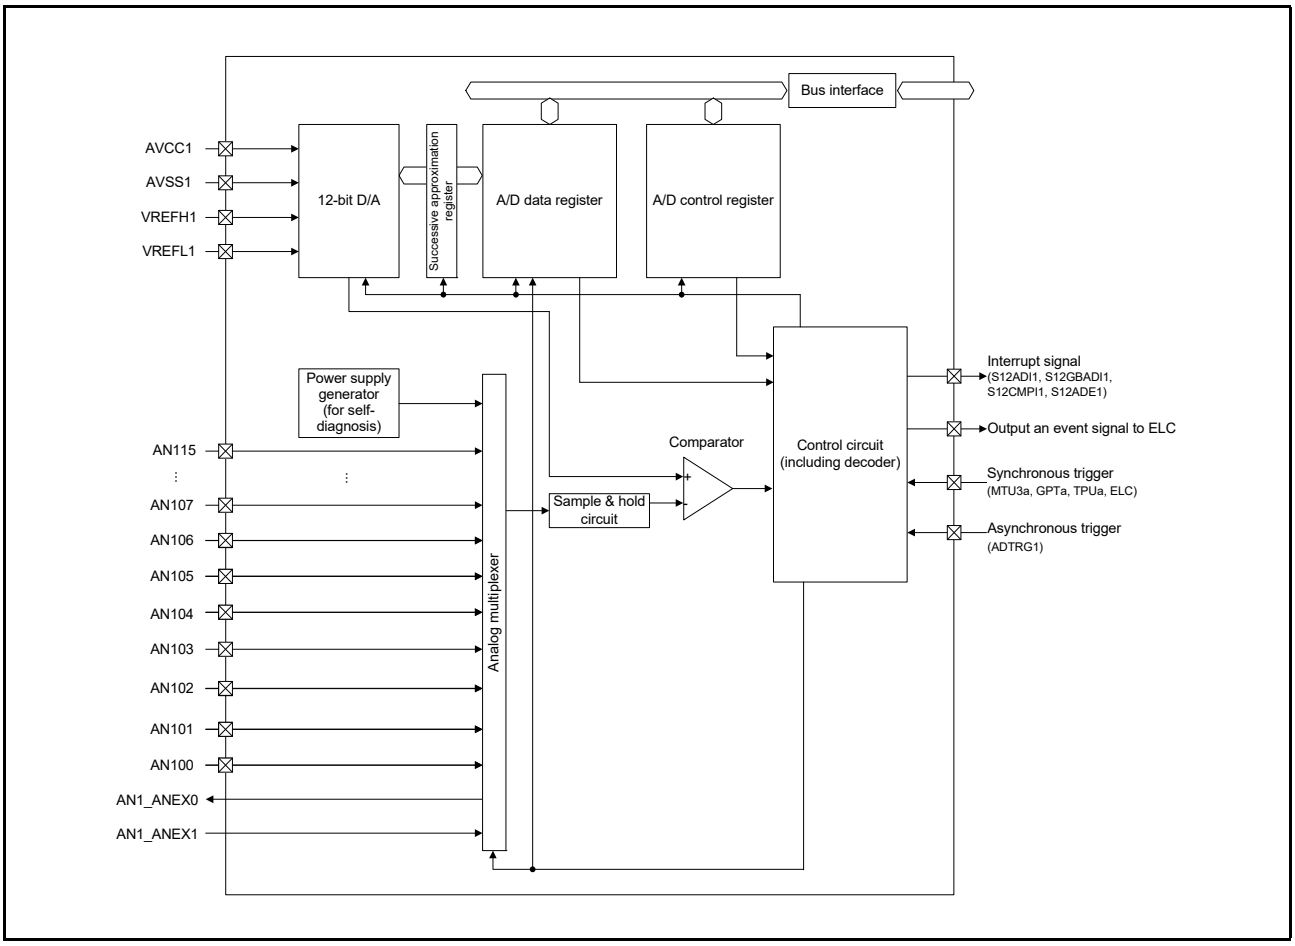

Figure 43.2 Block Diagram of 12-Bit A/D Converter (Unit 1)

Table 43.3 lists the I/O pins of the 12-bit A/D converter.

Table 43.3 I/O Pins of 12-Bit A/D Converter

Unit	Pin Name	I/O	Function
Unit 0	AVCC0	Input	Analog block power supply pin
	AVSS0	Input	Analog block ground pin
	VREFH0	Input	Reference power supply pin
	VREFL0	Input	Reference power supply ground pin
	AN000 to AN007	Input	Analog input pins 0 to 7
	ADTRG0	Input	External trigger input pin for starting A/D conversion
Unit 1	AVCC1	Input	Analog block power supply pin
	AVSS1	Input	Analog block ground pin
	VREFH1	Input	Analog block power supply pin
	VREFL1	Input	Analog block ground pin
	AN100 to AN115	Input	Analog input pins 8 to 23
	AN1_ANEX0	Output	Extended analog output pin
	AN1_ANEX1	Input	Extended analog input pin
	ADTRG1	Input	External trigger input pin for starting A/D conversion

43.2 Register Descriptions

43.2.1 A/D Data Registers y (ADDRy), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR)

The ADDRy registers (y = 0 to 7 in unit 0; y = 0 to 15 in unit 1) are 16-bit read-only registers for storing the result of A/D conversion. Register ADDBLDR is a 16-bit read-only register for storing the result of A/D conversion in response to the second trigger in double trigger mode. Registers ADDBLDRA and ADDBLDRB are 16-bit read-only registers for storing the result of A/D conversion during extended operation in double trigger mode. Register ADTSDR is a 16-bit read-only register for storing the A/D conversion result of temperature sensor output.
The formats for data in the ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, and ADTSDR registers vary according to the following conditions.

- The setting of the A/D data register format select bit (ADCER.ADRFT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D conversion-accuracy selection bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit is selectable.)
- The setting of the addition frequency select bits (ADADC.ADC[1:0]) (once, twice, three times, or four times is selectable.)
- The setting of the average mode enable bit (ADADC.AVEE) (Addition or average is selectable.)

The data formats for each given condition are shown below.

(1) When A/D-converted value addition/average mode is not selected

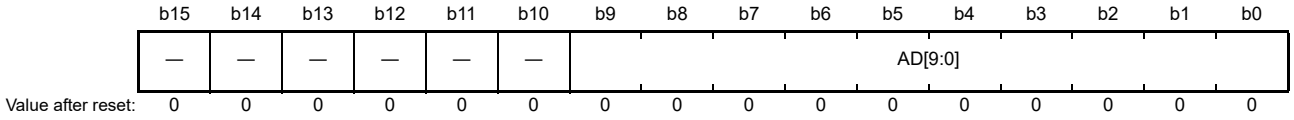
- The settings for flush-right data with 12-bit accuracy

Address(es): S12ADC0.ADDBLDR A008 C018h, S12ADC0.ADTSDR A008 C01Ah, S12ADC0.ADDR0 A008 C020h, S12ADC0.ADDR1 A008 C022h, S12ADC0.ADDR2 A008 C024h, S12ADC0.ADDR3 A008 C026h, S12ADC0.ADDR4 A008 C028h, S12ADC0.ADDR5 A008 C02Ah, S12ADC0.ADDR6 A008 C02Ch, S12ADC0.ADDR7 A008 C02Eh, S12ADC0.ADDBLDRA A008 C084h, S12ADC0.ADDBLDRB A008 C086h S12ADC1.ADDBLDR A008 C418h, S12ADC1.ADDR0 A008 C420h, S12ADC1.ADDR1 A008 C422h, S12ADC1.ADDR2 A008 C424h, S12ADC1.ADDR3 A008 C426h, S12ADC1.ADDR4 A008 C428h, S12ADC1.ADDR5 A008 C42Ah, S12ADC1.ADDR6 A008 C42Ch, S12ADC1.ADDR7 A008 C42Eh, S12ADC1.ADDR8 A008 C430h, S12ADC1.ADDR9 A008 C432h, S12ADC1.ADDR10 A008 C434h, S12ADC1.ADDR11 A008 C436h, S12ADC1.ADDR12 A008 C438h, S12ADC1.ADDR13 A008 C43Ah, S12ADC1.ADDR14 A008 C43Ch, S12ADC1.ADDR15 A008 C43Eh, S12ADC1.ADDBLDRA A008 C484h, S12ADC1.ADDBLDRB A008 C486h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

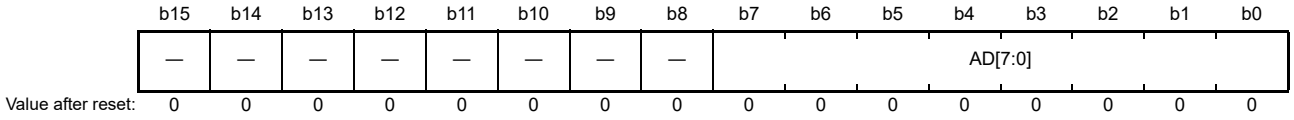
Bit	Symbol	Bit Name	Description	R/W
b11 to b0	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R
b15 to b12	—	Reserved	These bits are read as 0.	R

- The settings for flush-right data with 10-bit accuracy



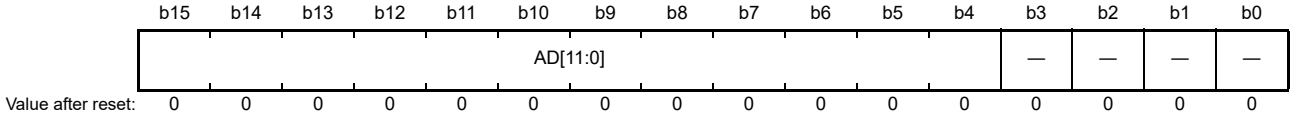
Bit	Symbol	Bit Name	Description	R/W
b9 to b0	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R
b15 to b10	—	Reserved	These bits are read as 0.	R

- The settings for flush-right data with 8-bit accuracy



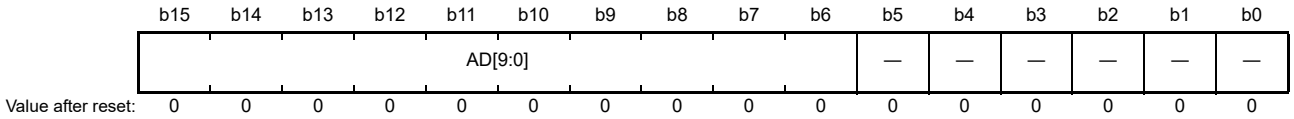
Bit	Symbol	Bit Name	Description	R/W
b7 to b0	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R
b15 to b8	—	Reserved	These bits are read as 0.	R

- The settings for flush-left data with 12-bit accuracy



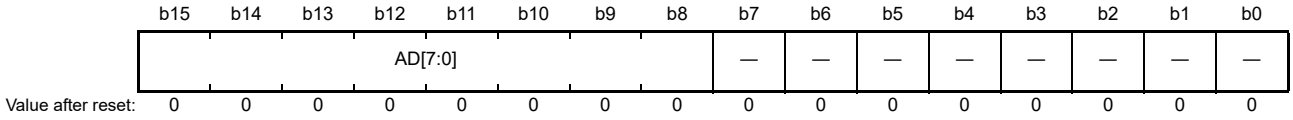
Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0.	R
b15 to b4	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R

- The settings for flush-left data with 10-bit accuracy



Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0.	R
b15 to b6	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R

- The settings for flush-left data with 8-bit accuracy



Bit	Symbol	Bit Name	Description	R/W
b7 to b0	—	Reserved	These bits are read as 0.	R
b15 to b8	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R

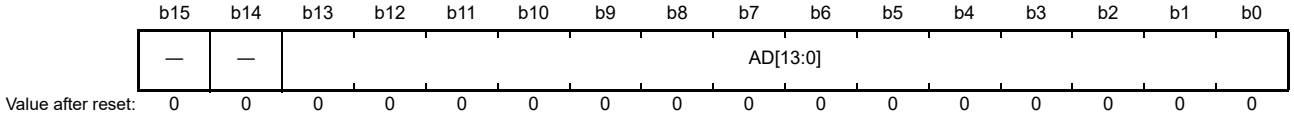
(2) When A/D-converted value average mode is selected

When A/D-converted value average mode is selected, the AD[11:0] bits indicate the mean of A/D-converted values on a specific channel. Even if A/D-converted value average mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bit in the same way as normal A/D conversion.

(3) When A/D-converted value addition mode is selected

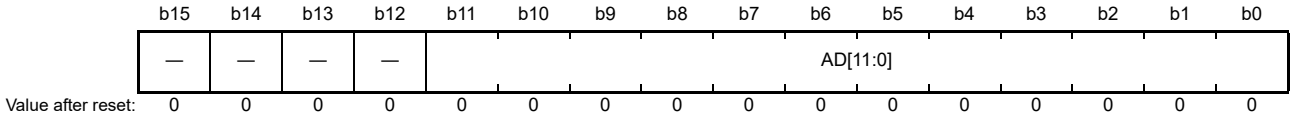
When A/D-converted value addition mode is selected, the AD[13:0] bits indicate the value that is obtained by adding up A/D-converted values on a specific channel. In A/D-converted value addition mode, the value obtained by adding up of A/D conversion results is retained in the A/D data register as a 2-bit-extended value of the conversion accuracy specified. Even if A/D-converted value addition mode is selected, the value is stored in the A/D data register according to the settings of the A/D data register format select bits.
The data formats for each given condition are shown below.

- The settings for flush-right data with 12-bit accuracy (when A/D-converted value addition mode is selected)



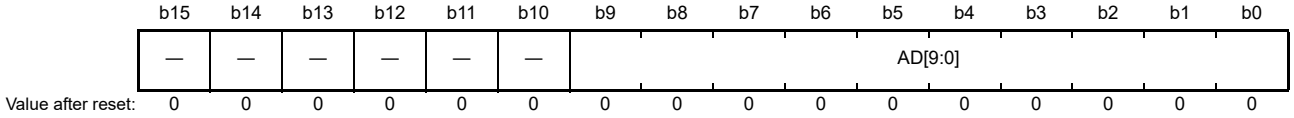
Bit	Symbol	Bit Name	Description	R/W
b13 to b0	AD[13:0]	Added Value 13 to 0	14-bit value obtained by adding up of A/D conversion results	R
b15, b14	—	Reserved	These bits are read as 0.	R

- The settings for flush-right data with 10-bit accuracy (when A/D-converted value addition mode is selected)



Bit	Symbol	Bit Name	Description	R/W
b11 to b0	AD[11:0]	Added Value 11 to 0	12-bit value obtained by adding up of A/D conversion results	R
b15 to b12	—	Reserved	These bits are read as 0.	R

- The settings for flush-right data with 8-bit accuracy (when A/D-converted value addition mode is selected)

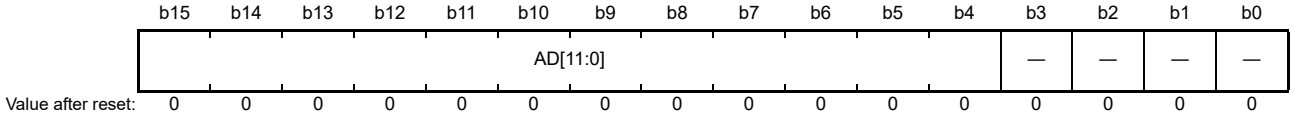


Bit	Symbol	Bit Name	Description	R/W
b9 to b0	AD[9:0]	Added Value 9 to 0	10-bit value obtained by adding up of A/D conversion results	R
b15 to b10	—	Reserved	These bits are read as 0.	R

- The settings for flush-left data with 12-bit accuracy (when A/D-converted value addition mode is selected)

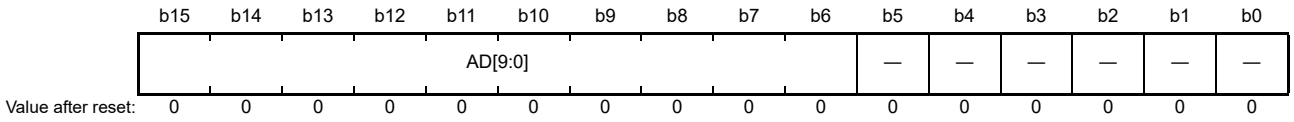
Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0.	R
b15 to b2	AD[13:0]	Added Value 13 to 0	14-bit value obtained by adding up of A/D conversion results	R

- The settings for flush-left data with 10-bit accuracy (when A/D-converted value addition mode is selected)



Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0.	R
b15 to b4	AD[11:0]	Added Value 11 to 0	12-bit value obtained by adding up of A/D conversion results	R

- The settings for flush-left data with 8-bit accuracy (when A/D-converted value addition mode is selected)



Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0.	R
b15 to b6	AD[9:0]	Added Value 9 to 0	10-bit value obtained by adding up of A/D conversion results	R

43.2.2 A/D Self-Diagnosis Data Register (ADRD)

ADRD is a 16-bit read-only register that holds the A/D conversion results based on the 12-bit A/D converter's self-diagnosis. In addition to the AD bit indicating A/D-converted value, the self-diagnosis status bit (DIAGST) is included in. In the ADRD register, the following different formats are used depending on the conditions below.

- The setting of the A/D data register format select bit (ADCER.ADRFT) (determining whether the data are flush-left or flush-right in the registers)
- The setting of the A/D conversion-accuracy selection bits (ADCER.ADPRC[1:0]) (8-, 10-, or 12-bit is selectable.)

The A/D-converted value addition mode and A/D-converted value average mode cannot be applied to the A/D self-diagnosis function. For details of self-diagnosis, see section 43.2.8 A/D Control Extended Register (ADCER). The data formats for each given condition are shown below.

- The settings for flush-right data with 12-bit accuracy

Address(es): S12ADC0.ADRD A008 C01Eh, S12ADC1.ADRD A008 C41Eh

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	AD[11:0]											
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b11 to b0	AD[11:0]	Converted Value 11 to 0	12-bit A/D-converted value	R
b13, b12	—	Reserved	These bits are read as 0.	R
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 43.2.8 A/D Control Extended Register (ADCER).	R

Note 1. "Reference voltage" refers to VREFH0 for unit 0 and to VREFH1 for unit 1.

- The settings for flush-right data with 10-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	—	—	AD[9:0]									
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b9 to b0	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R
b13 to b10	—	Reserved	These bits are read as 0.	R
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 43.2.8 A/D Control Extended Register (ADCER).	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to VREFH1 for unit 1.

- The settings for flush-right data with 8-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	DIAGST[1:0]		—	—	—	—	—	—	AD[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R
b13 to b8	—	Reserved	These bits are read as 0.	R
b15, b14	DIAGST[1:0]	Self-Diagnosis Status	b15 b14 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 43.2.8 A/D Control Extended Register (ADCER).	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to VREFH1 for unit 1.

- The settings for flush-left data with 12-bit accuracy

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	DIAGST[1:0]	Self-Diagnosis Status	b1 b0 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 43.2.8 A/D Control Extended Register (ADCER).	R
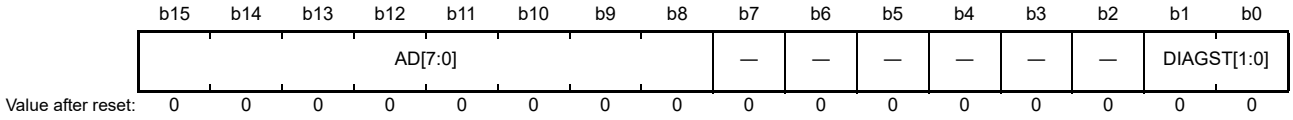
b5 to b2	—	Reserved	These bits are read as 0.	R
b15 to b6	AD[9:0]	Converted Value 9 to 0	10-bit A/D-converted value	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to VREFH1 for unit 1.

- The settings for flush-left data with 8-bit accuracy



Bit	Symbol	Bit Name	Description	R/W
b1, b0	DIAGST[1:0]	Self-Diagnosis Status	b1 b0 0 0: Self-diagnosis has never been executed since power-on. 0 1: Self-diagnosis using the voltage of 0 V has been executed. 1 0: Self-diagnosis using the voltage of reference power supply*1 × 1/2 has been executed. 1 1: Self-diagnosis using the voltage of reference power supply*1 has been executed. For details of self-diagnosis, see section 43.2.8 A/D Control Extended Register (ADCER).	R
b7 to b2	—	Reserved	These bits are read as 0.	R
b15 to b8	AD[7:0]	Converted Value 7 to 0	8-bit A/D-converted value	R

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to VREFH1 for unit 1.

43.2.3 A/D Control Register (ADCSR)

ADCSR sets double trigger mode, A/D conversion start trigger; enables or disables scan end interrupt; selects the scan mode; and starts or stops A/D conversion.

Address(es): S12ADC0.ADCSR A008 C000h, S12ADC1.ADCSR A008 C400h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	DBLANS[4:0]	Double Trigger Channel Select	These bits select one analog input channel for double triggered operation. The setting is only effective while double trigger mode is selected.	R/W
b5	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b6	GBADIE	Group B Scan End Interrupt Enable	0: Disables S12GBADI interrupt generation upon group B scan completion. 1: Enables S12GBADI interrupt generation upon group B scan completion.	R/W
b7	DBLE	Double Trigger Mode Select	0: Deselects double trigger mode. 1: Selects double trigger mode.	R/W
b8	EXTRG	Trigger Select*1	0: A/D conversion is started by a synchronous trigger (MTU3a, GPTa, TPUa, ELC). 1: A/D conversion is started by the asynchronous trigger (ADTRG0 in unit 0; ADTRG1 in unit 1).	R/W
b9	TRGE	Trigger Start Enable	0: Disables A/D conversion to be started by the synchronous or asynchronous trigger. 1: Enables A/D conversion to be started by the synchronous or asynchronous trigger.	R/W
b11, b10	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b12	ADIE	Scan End Interrupt Enable	0: Disables S12ADI interrupt generation upon scan completion. 1: Enables S12ADI interrupt generation upon scan completion.	R/W
b14, b13	ADCS[1:0]	Scan Mode Select	b14 b13 0 0: Single scan mode 0 1: Group scan mode 1 0: Continuous scan mode 1 1: Setting prohibited	R/W
b15	ADST	A/D Conversion Start	0: Stops A/D conversion process. 1: Starts A/D conversion process.	R/W

Note 1. Starting A/D conversion using an external pin (asynchronous trigger)
After a low-level signal is input to the external pin (ADTRG0 in unit 0; ADTRG1 in unit 1), write 1 to both the TRGE and EXTRG bits in ADCSR and change the signals of ADTRG0 in unit 0 and ADTRG1 in unit 1 to the high level. Thus the rising edge of ADTRG0 in unit 0 and ADTRG1 in unit 1 are detected and the scan conversion process is started. In this case, the pulse width of the high-level input must be at least 1.5 clock cycles of PCLK.

DBLANS[4:0] Bits (Double Trigger Channel Select)

The DBLANS[4:0] bits select one of the channels for A/D conversion data duplication in double trigger mode. The A/D conversion results of the analog input of the channel selected by the DBLANS[4:0] bits are stored into the A/D data register y when conversion is started by the first trigger in double trigger mode, and into the A/D data duplication register when started by the second trigger. Table 43.4 shows selection of the channel for double triggered operation.
When double trigger mode is selected, the channels selected by the ADANSA register are invalid, and the channel selected by the DBLANS[4:0] bits is subjected to A/D conversion instead.
When double trigger mode is used, do not select A/D conversion for the temperature sensor output and extended analog input. The DBLANS[4:0] bits should be set while the ADST bit is 0. (They should not be set simultaneously when 1 is written to the ADST bit.)
To use A/D-converted value addition/average mode while double trigger mode is set, the channel selected by the DBLANS[4:0] bits should be selected in the ADANSA register.

Table 43.4 Relationship between DBLANS Bit Settings and Double Trigger Enabled Channels

Unit 0		Unit 1			
DBLANS[4:0]	Duplication channel	DBLANS[4:0]	Duplication channel	DBLANS[4:0]	Duplication channel
00000	AN000	00000	AN100	01000	AN108

00111	AN007	00111	AN107	01111	AN115

Note: Settings other than above are prohibited.

GBADIE Bit (Group B Scan End Interrupt Enable)

The GBADIE bit sets whether to enable or disable group B scan end interrupt (S12GBADI) in group scan mode.

DBLE Bit (Double Trigger Mode Select)

Double trigger mode has a function to store the resulting data of A/D conversion started by the first and second synchronous triggers into separate registers.
When double trigger mode is selected, the channels specified in the ADANS register are invalid and the channel selected by the DBLANS[4:0] bits is effective instead. Double trigger mode is only operated by the synchronous trigger (MTU3a, GPTa, TPUa, ELC) selected by the ADSTRGR.TRSA[5:0] bits. Neither asynchronous trigger nor software trigger can be operated in double trigger mode. The A/D conversion results started by the first trigger are stored into the A/D data register y and those started by the second trigger are stored into the A/D data duplication register. In this case, if the ADIE bit is set to 1, the interrupt is output not upon completion of the first scan but upon completion of the second scan.
In continuous scan mode, double trigger mode should not be selected. Also do not select double trigger mode for conversion of temperature sensor output.
The DBLE bit should be set after the ADST bit has been set to 0.

EXTRG Bit (Trigger Select)

The EXTRG bit selects the synchronous trigger or the asynchronous trigger as the trigger for starting A/D conversion.

TRGE Bit (Trigger Start Enable)

The TRGE bit sets whether to enable or disable starting of A/D conversion by the synchronous trigger and the asynchronous trigger.

This bit should be set to 1 in group scan mode.

ADIE Bit (Scan End Interrupt Enable)

The ADIE bit sets whether to enable or disable generation of the A/D scan end interrupt (S12ADI) in group scan mode (except for group B scan).
With double trigger mode deselected, the S12ADI interrupt is generated after the first scan is completed if the ADIE bit is set to 1.
With the extended analog input selected, the S12ADI interrupt is generated after A/D conversion is completed if the ADIE bit is set to 1.
With double trigger mode selected, the S12ADI interrupt is generated after the second scan is completed if the ADIE bit is set to 1 as long as the scan is started by the synchronous trigger (MTU3a, GPTa, TPUa, ELC) selected by the ADSTRGR.TRSA[5:0] bits.

ADCS[1:0] Bits (Scan Mode Select)

The ADCS bit select the scan mode.
In single scan mode, A/D conversion is performed for the analog inputs of a maximum of eight channels in unit 0 and 16 channels in unit 1 selected with the ADANSA register in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, the scan conversion is stopped.*1
In continuous scan mode, while the ADST bit in ADCSR is 1, A/D conversion is performed for the analog inputs of a maximum of eight channels in unit 0 and 16 channels in unit 1 selected with the ADANSA register in the ascending order of the channel number, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is repeated from the first channel. If the ADST bit in ADCSR is set to 0 during continuous scan, A/D conversion is stopped even if scanning is in progress.*1
In group scan mode, A/D conversion is performed for the analog inputs (group A) of a maximum of eight channels in unit 0 and 16 channels in unit 1 selected with the ADANSA register in the ascending order of the channel number after scanning is started by the synchronous trigger (MTU3a, GPTa, TPUa, ELC) selected by the TRSA[5:0] bits in ADSTRGR, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped. A/D conversion is also performed for the analog inputs (group B) of a maximum of eight channels in unit 0 and 16 channels in unit 1 selected with the ADANSB register in the ascending order of the channel number after scanning is started by the synchronous trigger (MTU3a, GPTa, TPUa, ELC) selected by the TRSB[5:0] bits in ADSTRGR, and when one cycle of A/D conversion is completed for all the selected channels, A/D conversion is stopped. If the conversion processes in group A and B occur at the same time, ADC cannot control those conversion separately. In this case, set the group A priority control setting bit (ADGSPCR.PGS) in the A/D group scan priority control register (ADGSPCR) to 1 in order to assign a priority to conversion of group A.*1
In group scan mode, different channels and triggers should be selected for group A and group B.
When the extended analog input is selected, single scan mode or continuous scan mode should be selected.
The ADCS[1:0] bits should be set while the ADST bit is 0 (it should not be set simultaneously when 1 is written to the ADST bit.)

Note 1. When the temperature sensor output is selected, A/D conversion of the designated analog input channels is followed by A/D conversion of the temperature sensor output.

Table 43.5 shows the selectable targets for A/D conversion depending on the settings of scan mode and double trigger mode.

Table 43.5 Selectable Targets for A/D Conversion Depending on the Settings of Scan Mode and Double Trigger Mode

		Targets for A/D Conversion				
Scan Mode Setting	Double Trigger Mode Setting	Self-Diagnosis	Analog Input (Including Group A)	Analog Input (Group B)	Temperature Sensor Output	Extended Analog Input
Single scan	DBLE = 0	√	√	×	√	√
	DBLE = 1	√	√ (1ch only)	×	×	×
Continuous scan	DBLE = 0	√	√	×	√	√
	DBLE = 1	×	×	×	×	×
Group scan	DBLE = 0	√	√	√	√	×
	DBLE = 1	×	√ (1ch only)	√	×	×

Note: √: Selectable; ×: Not selectable
Note: When the extended analog input is selected as a target for A/D conversion, other A/D conversion targets should not be selected.

ADST Bit (A/D Conversion Start)

The ADST bit starts or stops A/D conversion process.
Before the ADST bit is set to 1, set the A/D conversion clock, the conversion mode, and conversion target analog input.
[Setting conditions]
The ADST bit is set to 1 if one of the following conditions is satisfied:

- 1 is written by software.
- The synchronous trigger (MTU3a, GPTa, TPUa, ELC) selected by the ADSTRGR.TRSA[5:0] bits is detected with ADCSR.EXTRG and ADCSR.TRGE bits being set to 0 and 1, respectively.
- The synchronous trigger (MTU3a, GPTa, TPUa, ELC) selected by the ADSTRGR.TRSB[5:0] bits is detected with the ADCSR.TRGE bit being set to 1 in group scan mode.
- The asynchronous trigger is detected with the ADCSR.TRGE and ADCSR.EXTRG bits being set to 1 and the ADSTRGR.TRSA[5:0] bits being set to 000000b.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), a group B trigger is detected and A/D conversion of group B is started.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and A/D conversion of group B is restarted.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and A/D conversion of group B is started.

[Clearing conditions]

The ADST bit is cleared to 0 if one of the following conditions is satisfied:

- 0 is written by software.
- The A/D conversion of all the selected channels or the temperature sensor output is completed in single scan mode.
- The A/D conversion of the extended analog input is completed in single scan mode.
- Group A scan is completed in group scan mode.
- Group B scan is completed in group scan mode.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), a group A trigger is detected during group B A/D conversion and the scanning of group B is stopped.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRP bit is set to 1 and the scanning of group B started by a resumption trigger is completed.
- With group-A priority control operation mode enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), the ADGSPCR.GBRSCN bit is set to 1 and the scanning of group B by a trigger is completed.

Note: When group-A priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1), do not set the ADST bit to 1.

Note: When group-A priority control operation mode has been enabled (ADCSR.ADCS[1:0] bits = 01b and ADGSPCR.PGS bit = 1) and ADGSPCR.GBRP = 1, do not set the ADST bit to 0. When forcibly terminating A/D conversion, follow the procedure for clearing the ADST bit.

43.2.4 A/D Channel Select Register A (ADANSA)

ADANSA selects analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). In group scan mode, this register selects group A channels.

Address(es): S12ADC0.ADANSA A008 C004h, S12ADC1.ADANSA A008 C404h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ANSA[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ANSA[15:0]	A/D Conversion Channel Select	0: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are not subjected to conversion. 1: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are subjected to conversion.	R/W

ANSA[15:0] Bits (A/D Conversion Channel Select)

The ANSA[15:0] bits select analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). The channels to be selected and the number of channels can be arbitrarily set. In unit 0, the ANSA[0] bit corresponds to AN000 and the ANSA[7] bit corresponds to AN007. In unit 1, the ANSA[0] bit corresponds to AN100 and the ANSA[15] bit corresponds to AN115.

When double trigger mode is selected, the channel selected by the ANSA[15:0] bits is invalid, and the channel selected by the ADCSR.DBLANS[4:0] bits is selected in group A instead.

When group scan mode is selected, do not select the channels specified in the A/D channel select register B (ADANSB).

The ANSA[15:0] bits should be set while the ADCSR.ADST bit is 0.

43.2.5 A/D Channel Select Register B (ADANSB)

ADANSB selects analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) in group B when group scan mode is selected. The ADANSB register is not used in any scan mode other than group scan mode.

Address(es): S12ADC0.ADANSB A008 C014h, S12ADC1.ADANSB A008 C414h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ANSB[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ANSB[15:0]	A/D Conversion Channel Select	0: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are not subjected to conversion. 1: AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) are subjected to conversion.	R/W

ANSB[15:0] Bits (A/D Conversion Channel Select)

The ANSB[15:0] bits select analog input channels for A/D conversion among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) in group B when group scan mode is selected. The ADANSB register is used for group scan mode only; not used for any other modes. The channels specified in group A (the channels corresponding to group A, selected with the ADANSA register and the ADCSR.DBLANS[4:0] bits in double trigger mode) should be excluded as the channels to be selected and the number of channels to be set.

In unit 0, the ANSB[0] bit corresponds to AN000 and the ANSB[7] bit corresponds to AN007. In unit 1, the ANSB[0] bit corresponds to AN100 and the ANSB[15] bit corresponds to AN115.

The ANSB[15:0] bits should be set while the ADCSR.ADST bit is 0.

43.2.6 A/D-Converted Value Addition/Average Mode Select Register (ADADS)

ADADS selects the channels AN000 to AN007 and AN100 to AN115 on which A/D conversion is performed successively 2 to 4 times and then converted values are added (integrated) or averaged.

Address(es): S12ADC0.ADADS A008 C008h, S12ADC1.ADADS A008 C408h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	ADS[15:0]	A/D-Converted Value Addition/ Average Channel Select	0: A/D-converted value addition/average mode for AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) is not selected. 1: A/D-converted value addition/average mode for AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) is selected.	R/W

ADS[15:0] Bits (A/D-Converted Value Addition/Average Channel Select)

When the ADS[n] bit of the number that is the same as that of A/D-converted channel selected by the ANSA[n] bits (n = 0 to 7 in unit 0, or n = 0 to 15 in unit 1) in ADANSA or DBLANS[4:0] bits in ADCSR and ANSB[n] bits (n = 0 to 7 in unit 0, or n = 0 to 15 in unit 1) in ADANSB is set to 1, A/D conversion of analog input of the selected channels is performed successively 2 to 4 times that is set with the ADC[1:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is stored in the A/D data register. When the ADADC.AVEE bit is 1, the mean value of the results obtained by addition (integration) is stored in the A/D data register. As for the channel on which the A/D conversion is performed and addition/average mode is not selected, a normal one-time conversion is executed and the conversion result is stored to the A/D data register.

The ADS[15:0] bits should be set while the ADCSR.ADST bit is 0.

Figure 43.3 shows the scan sequence when ADS[2] and ADS[6] are set to 1.

It is assumed that the scan is operated in continuous scan mode (ADCS = 10b in ADCSR), addition mode is selected (ADADC.AVEE = 0), the number of additions is set to 3 (conversion is performed four times) (ADADC.ADC[1:0] = 11b), and AN000 to AN007 is selected (ADANSA.ANSA[15:0] = 00FFh). Conversion is started from AN000. Conversion for AN002 is performed four times, and the value obtained by addition (integration) is stored in the A/D data register 2. Then, conversion for AN003 is started. Conversion for AN006 is performed four times successively, and the value obtained by addition (integration) is stored in the A/D data register 6. After conversion of AN007 is completed, the same sequence repeats from AN000.

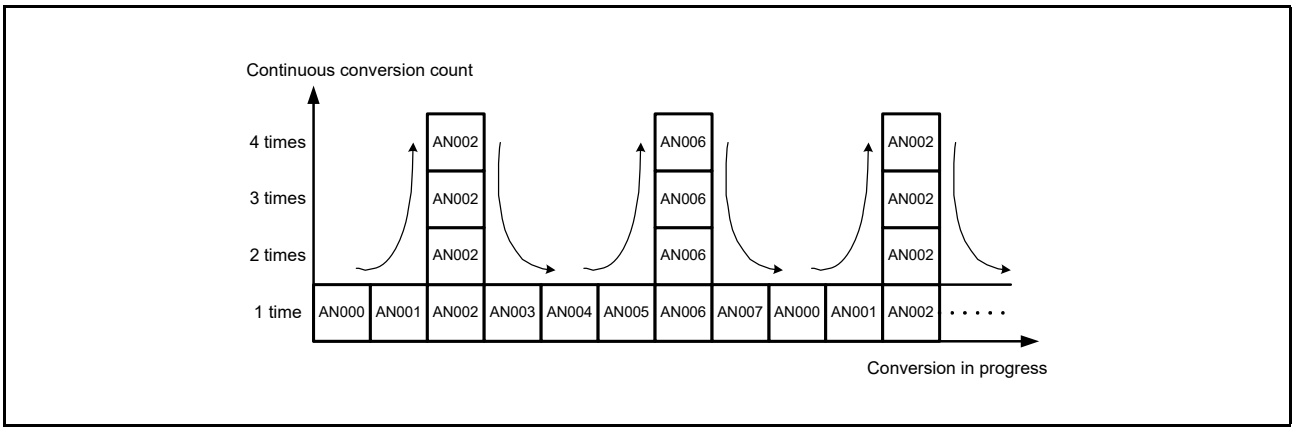

Figure 43.3 Scan Conversion Sequence with ADADC.ADC[1:0] = 11b, ADADC.AVEE = 0, ADS[2] = 1, and ADS[6] = 1

43.2.7 A/D-Converted Value Addition/Average Count Select Register (ADADC)

ADADC sets the addition count and average count for A/D conversion of the channel for which A/D-converted value addition/average mode is selected and for A/D conversion of temperature sensor output, and selects either addition or average mode.

Address(es): S12ADC0.ADADC A008 C00Ch, S12ADC1.ADADC A008 C40Ch

	b7	b6	b5	b4	b3	b2	b1	b0
	AVEE	—	—	—	—	—	ADC[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	ADC[1:0]	Addition Count Select	b1 b0 0 0: 1-time conversion (no addition; same as normal conversion) 0 1: 2-time conversion (addition once) 1 0: 3-time conversion (addition twice)*1 1 1: 4-time conversion (addition three times)	R/W
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	AVEE	Average Mode Enable	0: Addition mode is selected. 1: Average mode is selected.	R/W

Note 1. When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[1:0] = 10b)

ADC[1:0] Bits (Addition Count Select)

The ADC[1:0] bits set the addition count common to the channels for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits), and to A/D conversion of temperature sensor output.

When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[1:0] = 10b).

The ADC[1:0] bits should be set while the ADCSR.ADST bit is 0. When self-diagnosis is executed (ADCER.DIAGM = 1), do not set the ADC[1:0] bits to any value other than 00b.

AVEE Bit (Average Mode Enable)

The AVEE bit selects addition or average mode for A/D conversion of the channel for which A/D conversion and A/D-converted value addition/average mode is selected, including the channels selected in double trigger mode (by ADCSR.DBLANS[4:0] bits) and temperature sensor output.

When average mode is selected by setting the ADADC.AVEE bit to 1, do not set the addition count to three times (ADADC.ADC[1:0] = 10b).

The AVEE bits should be set while the ADCSR.ADST bit is 0.

43.2.8 A/D Control Extended Register (ADCER)

ADCER sets self-diagnosis mode, format of the A/D data registers y (ADDRy), and automatic clearing of A/D data registers.

Address(es): S12ADC0.ADCER A008 C00Eh, S12ADC1.ADCER A008 C40Eh

Bit	Symbol	Bit Name	Description	R/W
b0	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b2, b1	ADPRC[1:0]	A/D Conversion Accuracy Specify	b2 b1 0 0: A/D conversion is performed with 12-bit accuracy. 0 1: A/D conversion is performed with 10-bit accuracy. 1 0: A/D conversion is performed with 8-bit accuracy. 1 1: Setting is prohibited.	R/W
b4, b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b5	ACE	A/D Data Register Automatic Clearing Enable	0: Disables automatic clearing. 1: Enables automatic clearing.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b9, b8	DIAGVAL[1:0]	Self-Diagnosis Conversion Voltage Select	b9 b8 0 0: Setting prohibited when self-diagnosis is enabled 0 1: Uses the voltage of 0 V for self-diagnosis. 1 0: Uses the voltage of reference power supply*1 × 1/2 for self-diagnosis. 1 1: Uses the voltage of reference power supply*1 for self-diagnosis.	R/W
b10	DIAGLD	Self-Diagnosis Mode Select	0: Rotation mode for self-diagnosis voltage 1: Fixed mode for self-diagnosis voltage	R/W
b11	DIAGM	Self-Diagnosis Enable	0: Disables self-diagnosis of 12-bit A/D converter. 1: Enables self-diagnosis of 12-bit A/D converter.	R/W
b14 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	ADRFMT	A/D Data Register Format Select	0: Right-alignment is selected for the A/D data register format. 1: Left-alignment is selected for the A/D data register format.	R/W

Note 1. “Reference voltage” refers to VREFH0 for unit 0 and to VREFH1 for unit 1.

ADPRC[1:0] Bits (A/D Conversion Accuracy Specify)

These bits select the A/D conversion accuracy among 8-, 10-, or 12-bit accuracy. When the A/D conversion accuracy is changed, the bit width of effective data stored in the result register and A/D conversion time are also changed.
See section 43.3.7 Analog Input Sampling and Scan Conversion Time for details.

ACE Bit (A/D Data Register Automatic Clearing Enable)

The ACE bit selects enabling or disabling of automatic clearing (all “0”) of the A/D data register (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, or ADTSDR) when reading any of these registers by the CPU or DMACA. Automatic clearing of the A/D data register enables a failure which has not been updated in the A/D data register to be detected.

DIAGVAL[1:0] Bits (Self-Diagnosis Conversion Voltage Select)

These bits select the voltage value used in self-diagnosis voltage fixed mode. For details, refer to the descriptions of the ADCER.DIAGLD bit.

Self-diagnosis should not be executed by setting the ADCER.DIAGLD bit to 1 when the ADCER.DIAGVAL[1:0] bits are set to 00b.

DIAGLD Bit (Self-Diagnosis Mode Select)

The DIAGLD bit selects whether the three voltage values are rotated or the fixed voltage is used in self-diagnosis. Setting this bit (ADCER.DIAGLD) to 0 allows conversion of the voltages in rotation mode where 0, the reference power supply × 1/2, and the reference power supply are converted in this order. If the self-diagnosis voltage rotation mode is selected after a reset, rotation starts at 0 V. The fixed voltage specified by the ADCER.DIAGVAL[1:0] bits is converted when self-diagnosis voltage fixed mode is selected. In self-diagnosis voltage rotation mode, the self-diagnosis voltage value does not return to 0 when scan conversion is completed. When scan conversion is restarted, therefore, rotation starts at the voltage value following the previous value. If fixed mode is switched to rotation mode, rotation starts at the fixed voltage value.

The DIAGLD bit should be set while the ADCSR.ADST bit is 0.

DIAGM Bit (Self-Diagnosis Enable)

The DIAGM bit selects execution of self-diagnosis.

Self-diagnosis is used to detect a failure of the 12-bit A/D converter. Specifically, it is used to convert the voltage value selected from the internally generated voltage values 0, the reference power supply × 1/2, and the reference power supply. When conversion is completed, information on the converted voltage and the conversion result is stored into the self-diagnosis data register (ADRD). ADRD can then be read out by software to determine whether the conversion result falls within the normal range (normal) or not (abnormal). Self-diagnosis is executed once at the beginning of each scan, and one of the three voltages is converted. The execution time of self-diagnosis differs from the A/D conversion time of one channel.

When self-diagnosis is selected in double trigger mode, self-diagnosis is executed only for the first scan conversion by a synchronous trigger (MTU3a, GPTa, TPUa, ELC), not executed in the second scan. When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed in group A and B.

The DIAGM bit should be set while the ADCSR.ADST bit is 0.

Self-diagnosis cannot be performed when extended analog input is used.

ADRFMT Bit (A/D Data Register Format Select)

The ADRFMT bit specifies right-alignment or left-alignment for the data to be stored in ADDRy, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR, ADRD, or ADCMPDRy.

For details on the format of each data register, see section 43.2.1 A/D Data Registers y (ADDRy), A/D Data Duplication Register (ADDBLDR), A/D Data Duplication Register A (ADDBLDRA), A/D Data Duplication Register B (ADDBLDRB), A/D Temperature Sensor Data Register (ADTSDR), section 43.2.2 A/D Self-Diagnosis Data Register (ADRD), and section 43.2.21 A/D Compare Data Register y (ADCMPDRy) (y = 0, 1).

43.2.9 A/D Start Trigger Select Register (ADSTRGR)

ADSTRGR selects the A/D conversion start trigger.

Address(es): S12ADC0.ADSTRGR A008 C010h, S12ADC1.ADSTRGR A008 C410h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	TRSA[5:0]						—	—	TRSB[5:0]					
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	TRSB[5:0]	A/D Conversion Start Trigger Select for Group B	Select the A/D conversion start trigger for group B in group scan mode.	R/W
b7, b6	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b13 to b8	TRSA[5:0]	A/D Conversion Start Trigger Select	Select the A/D conversion start trigger in single scan mode and continuous mode. In group scan mode, the A/D conversion start trigger for group A is selected.	R/W
b15, b14	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TRSB[5:0] Bits (A/D Conversion Start Trigger Select for Group B)

The TRSB[5:0] bits select the trigger to start scanning of the analog input selected in group B. The TRSB[5:0] bits require to be set only in group scan mode and are not used in any other scan mode. For the scan conversion start trigger for group B, setting a software trigger or an asynchronous trigger is prohibited. Therefore, the TRSB[5:0] bits should be set to the value other than 000000b and the ADCSR.TRGE bit should be set to 1 in group scan mode.

When group A is given priority in group scan mode, setting the ADGSPCR.GBRP bit to 1 allows group B to continuously operate in single scan mode. When setting the ADGSPCR.GBRP bit to 1, set the TRSB[5:0] bits to 3Fh.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by the trigger may have no effect.

Because an A/D conversion start trigger requires synchronization processing, a delay of the period for synchronization processing occurs. See section 43.3.7 Analog Input Sampling and Scan Conversion Time for details.

Table 43.6 lists the A/D conversion startup sources selected by the TRSB[5:0] bits.

TRSA[5:0] Bits (A/D Conversion Start Trigger Select)

The TRSA[5:0] bits select the trigger to start A/D conversion in single scan mode and continuous scan mode. In group scan mode, the trigger to start scanning of the analog input selected in group A is selected. When scanning is executed in group scan mode or double trigger mode, a software trigger and an asynchronous trigger cannot be used at the same time.

- When using the A/D conversion startup source of a synchronous trigger (MTU3a, GPTa, TPUa, ELC), set the TRGE bit in ADCSR to 1 and set the EXTRG bit in ADCSR to 0.
- When using the asynchronous trigger (ADTRGn), set the TRGE bit in ADCSR to 1 and set the EXTRG bit in ADCSR to 1.
- Software trigger (ADCSR.ADST) is enabled regardless of the settings of the ADCSR.TRGE bit, the ADCSR.EXTRG bit, and the TRSA[5:0] bits.

Note that the issuance period of trigger for A/D conversion must be more than or equal to the actual scan conversion time (tSCAN). If the issuance period is less than tSCAN, A/D conversion by a trigger may have no effect. Because an A/D conversion start trigger requires synchronization processing, a delay of the period for synchronization processing occurs. See section 43.3.7 Analog Input Sampling and Scan Conversion Time for details.

Table 43.7 lists the selection of A/D activation sources selected by the TRSA[5:0] bits.

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	TSSAD	Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select	0: Temperature sensor output A/D-converted value addition/average mode is not selected. 1: Temperature sensor output A/D-converted value addition/average mode is selected.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b8	TSSA	Temperature Sensor Output A/D Conversion Select	0: A/D conversion of temperature sensor output is disabled. 1: A/D conversion of temperature sensor output is enabled.	R/W
b9	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b10	TSSB	Temperature Sensor Output A/D Conversion Select	0: A/D conversion of temperature sensor output is disabled. 1: A/D conversion of temperature sensor output is enabled.	R/W
b15 to b11	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

TSSAD Bit (Temperature Sensor Output A/D-Converted Value Addition/Average Mode Select)

This bit selects A/D conversion of the temperature sensor output. When the TSSAD bit is set to 1, A/D conversion of the temperature sensor output is selected and performed successively 2 to 4 times that is set with the ADC[1:0] bits in ADADC. When the ADADC.AVEE bit is 0, the value obtained by addition (integration) is returned to the A/D temperature sensor data register (ADTSDR). When the ADADC.AVEE bit is 1, the mean value is returned to ADTSDR. The TSSAD bit should be set while the ADCSR.ADST bit is 0.

TSSA Bit (Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group A in single scan mode, continuous scan mode or group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.
The TSSA bit should be set while the ADCSR.ADST bit is 0.

TSSB Bit (Temperature Sensor Output A/D Conversion Select)

This bit selects A/D conversion of the temperature sensor output for group B in group scan mode. When A/D conversion of the temperature sensor output is selected and performed, set the ADCSR.DBLE bit to 0.
The TSSB bit should be set while the ADCSR.ADST bit is 0. Do not set the TSSB bit to 1 while the TSSA bit is 1.

43.2.11 A/D Conversion Extended Input Control Register (ADEXICR) Unit1 (without Temperature Sensor and with Extended Analog Input)

ADEXICR controls temperature sensor output and extended analog input and output.

Address(es): S12ADC1.ADEXICR A008 C412h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

b14, b13	EXSEL[1:0]	Extended Analog Input Select	b14 b13 0 0: Analog input channel (ANn pin) 0 1: AN1_ANEX1 pin 1 0: Setting is prohibited. 1 1: Setting is prohibited.	R/W
b15	EXOEN	Extended Analog Output Control	0: Output is disabled. 1: Output is enabled.	R/W

EXSEL[1:0] Bits (Extended Analog Input Select)

These bits select the extended analog input pin (AN1_ANEX1) instead of the analog input channels (ANn).
When the AN1_ANEX1 pin is selected, AN1_ANEX0 pin output should be input to the AN1_ANEX1 pin via the external operational amplifier. In this case, only select AN100 to AN107; do not select AN108 to AN115. For details, see section 43.3.5.1 Usage of AN1_ANEX1.
When the AN1_ANEX1 pin is selected, self-diagnosis function cannot be used.

EXOEN Bit (Extended Analog Output Control)

This bit controls the extended analog output (AN1_ANEX0). When the output is enabled, the multiplexed value of AN100 to AN107 among analog input channels in unit 1 is output to the AN1_ANEX0 pin. Do not enable an output when the EXSEL[1:0] bits are 00b.

43.2.12 A/D Sampling State Register n (ADSSTRn) (n = 0 to 7, L, T)

The ADSSTRn register sets the sampling time for analog input.
If one state is one ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 11 states. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK clock is slow, the sampling time can be adjusted by the value of SST[7:0] bits. The SST[7:0] bits should be set while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 5 states or more and is 255 or less.
Table 43.8 shows the relationship between the A/D sampling state register and the relevant channels.
For details, refer to section 43.3.7 Analog Input Sampling and Scan Conversion Time.

Note 1. When self-diagnosis function is selected, the sampling time set by the ADSSTR0.SST[7:0] bits is applied to it.

43.2.13 A/D Sample and Hold Circuit Control Register (ADSHCR)

ADSHCR sets the parameters related to channel-dedicated sample-and-hold circuits.

Address(es): S12ADC0.ADSHCR A008 C066h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	SHANS[3:0]				SSTSH[7:0]							
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b7 to b0	SSTSH[7:0]	Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting	Set the sampling time (4 to 255 states).	R/W
b11 to b8	SHANS[3:0]	Channel-Dedicated Sample-and-Hold Circuit Bypass Select	Select whether to use or not use (bypass) AN000 to AN003 channel-dedicated sample-and-hold circuits. 0: Bypass the channel-dedicated sample-and-hold circuits. 1: Use the channel-dedicated sample-and-hold circuits.	R/W
b15 to b12	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

SSTSH[7:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Sampling Time Setting)

The SSTSH[7:0] bits set the sampling time for the channel-dedicated sample-and-hold circuits. If one state is one ADCLK (A/D conversion clock) cycle and the ADCLK clock is 60 MHz, one state is 16.7 ns. The initial value is 24 states. If the impedance of analog input signal source is too high to secure sufficient sampling time or if the ADCLK clock is slow, the sampling time can be adjusted. The SSTSH[7:0] bits should be set while the ADCSR.ADST bit is 0. The sampling time must be set to a value that is 4 states or more and is 255 or less. Also, the sampling time must be 0.4 µs or more.

SHANS[3:0] Bits (Channel-Dedicated Sample-and-Hold Circuit Bypass Select)

The SHANS[3:0] bits select whether to use or not use (bypass) AN000 to AN003 channel-dedicated sample-and-hold circuits. The SHANS[0] bit selects AN000, SHANS[1] bit selects AN001, SHANS[2] bit selects AN002, and SHANS[3] bit selects AN003. The SHANS[3:0] bits should be set while the ADST bit in ADCSR is 0.

If any channel from among AN000 to AN003 is selected for group B while operation is in group scan mode under group A priority control, make the setting to bypass the channel's dedicated sample-and-hold circuit.

The channels in unit 1 do not include channel-dedicated sample-and-hold circuits.

43.2.14 A/D Disconnection Detection Control Register (ADDISCR)

ADDISCR sets the disconnection detection assist function.

Address(es): S12ADC0.ADDISCR A008 C07Ah, S12ADC1.ADDISCR A008 C47Ah

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	ADNDIS[4:0]				
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b4 to b0	ADNDIS[4:0]	Disconnection Detection Assist Setting	Disconnection detection assist function is set.	R/W
b7 to b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

ADNDIS[4:0] Bits (Disconnection Detection Assist Setting)

These bits selects either precharge or discharge and the period of precharge/discharge for the A/D disconnection detection assist function. Setting the ADNDIS[4] bit = 1 allows to select precharge and setting the ADNDIS[4] bit = 0 allows to select discharge. The period of precharge/discharge can be set with the ADNDIS[3:0] bits. When the ADNDIS[3:0] bits = 0000b, the disconnection detection assist function is not effective. Setting of the ADNDIS[3:0] bits to 0001b is prohibited. Except for the case of ADNDIS[3:0] = 0000b or 0001b, the specified value indicates the number of states for the period of precharge/discharge. When the temperature sensor output is converted or self-diagnosis is used, the disconnection detection assistance cannot be used. In that case, the ADNDIS[3:0] bits should be set to 0000b. When the ADNDIS[3:0] bits are set to any values other than 0000b or 0001b, and the disconnection detection assistance is enabled, the disconnection detection assistance for the channel-dedicated sample-and-hold circuit is also enabled. Note that if ADEXICR.EXSEL[1:0] and ADEXICR.EXOEN are set to any values other than ADEXICR.EXSEL[1:0] = 00b and ADEXICR.EXOEN = 0b, and the disconnection detection assistance is enabled, A/D conversion cannot be executed correctly. In such a case, disable the disconnection detection assistance function. Also, disable this function when pin-level self-diagnosis is executed.

43.2.15 A/D Group Scan Priority Control Register (ADGSPCR)

ADGSPCR is used to make settings for priority control of A/D conversion for group A in group scan mode.

Address(es): S12ADC0.ADGSPCR A008 C080h, S12ADC1.ADGSPCR A008 C480h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	GBRP	—	—	—	—	—	—	—	—	—	—	—	—	—	GBRSCN	PGS
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PGS	Group-A Priority Control Setting*1	0: Operation is without group A priority control 1: Operation is with group A priority control	R/W
b1	GBRSCN	Group B Restart Setting	(Enabled only when PGS = 1. Set 0 when PGS = 0.) 0: Scanning for group B is not restarted when priority control is performed for group A. 1: Scanning for group B is restarted when priority control is performed for group A.	R/W
b14 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b15	GBRP	Group B Single Scan Continuous Start*2	(Enabled only when PGS = 1. Set 0 when PGS = 0.) 0: Single scan for group B is not continuously activated. 1: Single scan for group B is continuously activated.	R/W

Note 1. When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.
Note 2. When the GBRP bit has been set to 1, single scan is performed continuously for group B regardless of the setting of the GBRSCN bit.

PGS Bit (Group A Priority Control Setting)

This bit sets the priority of operation on group A. Set this bit to 1 when giving priority to operation on group A.
When the PGS bit is to be set to 1, the ADCSR.ADCS[1:0] bits must be set to 01b (group scan mode). If the bits are set to any other values, proper operation cannot be guaranteed.
When the PGS bit has been set to 0, A/D conversion must be stopped according to section 43.5.2 Notes on Stopping A/D Conversion. When the PGS bit has been set to 1, make register settings according to section 43.3.4.3 Operation under Group-A Priority Control.

GBRSCN Bit (Group B Restart Setting)

This bit controls the restarting of scan operation on group B when operation on group A is given priority.
If a scan operation on group B has been stopped by a group A trigger input with the GBRSCN bit set to 1, the scan operation is restarted on completion of the A/D conversion on group A. Also, if a group B trigger is input during A/D conversion on group A, the scan operation on group B is restarted on completion of the A/D conversion on group A.
However, when this function is to be used, set the ratio between the frequency divisors for PCLKH and ADCLK to 1:1. This function cannot be used if the frequency division settings are not in accord with this.
If the GBRSCN bit has been set to 0, triggers that are input during A/D conversion are ignored. Also, the ADCSR.ADST bit must be 0 when the GBRSCN bit is to be set.
The setting of the GBRSCN bit has an effect when the PGS bit is set to 1.

GBRP Bit (Group B Single Scan Continuous Start)

This bit is set when a single scan operation is to be performed continuously on group B.
Setting the GBRP bit to 1 starts a single scan on group B. On completion of the scan, another single scan on group B is automatically started. If an A/D conversion on group B has been stopped due to an operation on group A that takes priority, single scan on group B is automatically restarted on completion of the A/D conversion on group A.
Disable group B trigger input before setting the GBRP bit to 1. Setting the GBRP bit to 1 invalidates the setting of the GBRSCN bit. The ADCSR.ADST bit must be 0 when the GBRP bit is to be set.
The setting of the GBRP bit is valid when the PGS bit is 1.

43.2.16 A/D Compare Control Register (ADCMPCR)

ADCMPCR is used to set compare function.

Address(es): S12ADC0.ADCMPCR A008 C090h, S12ADC1.ADCMPCR A008 C490h

	b7	b6	b5	b4	b3	b2	b1	b0
	CMPIE	WCMPE	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b5 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b6	WCMPE	Window Function	0: Window function disabled 1: Window function enabled	R/W
b7	CMPIE	Compare Interrupt Enable	0: Generation of an S12CMPI interrupt in response to matches with a condition for comparison is disabled. 1: Generation of an S12CMPI interrupt in response to matches with a condition for comparison is enabled.	R/W

WCMPE Bit (Window Function)

Set enable/disable of Window function.
For details about Window function, see section 43.2.19 A/D Compare Level Register (ADCMPLR).

CMPIE Bit (Compare Interrupt Enable)

This bit selects whether to enable or disable generation of a compare interrupt (S12CMPI) in response to a match.

43.2.17 A/D Compare Channel Select Register (ADCMPANSR)

ADCMPANSR is used to select analog input channels for comparison from among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1).

Address(es): S12ADC0.ADCMPANSR A008 C094h, S12ADC1.ADCMPANSR A008 C494h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPS[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPS[15:0]	Compare Channel Select	0: The corresponding channel from among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) is not a target for comparison. 1: The corresponding channel from among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1) is a target for comparison.	R/W

CMPS[15:0] Bits (Compare Channel Select)

Setting the CMPS[n] bit which has the same number as the A/D channel selected by the ADANSA.ANSA[n] (n = 0 to 7 for unit 0, n = 0 to 15 for unit 1) or ADANSB.ANSB[n] (n = 0 to 7 for unit 0, n = 0 to 15 for unit 1) bit to 1 enables comparison with that channel.

Set the CMPS0[15:0] bits while ADCSR.ADST bit is 0.

The CMPS[15:8] bits of the unit 0 are reserved bits. Reading to these bits returns 0. Writing value should be 0.

43.2.18 A/D Compare Channel Select Extended Register (ADCMPANSER)

ADCMPANSER sets whether to use the temperature sensor output for comparison.

Address(es): S12ADC0.ADCMPANSER A008 C092h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPSTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPSTS	Temperature Sensor Output Compare Select	0: Temperature sensor output is not a target for comparison. 1: Temperature sensor output is a target for comparison.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPSTS Bit (Temperature Sensor Output Compare Select)

Setting the CMPSTS bit to 1 while ADEXICR.TSSA or ADEXICR.TSSB = 1 enables comparison.

43.2.19 A/D Compare Level Register (ADCMPLR)

The ADCMPLR register sets the condition for use in comparing the values of the ADCMPDR0 and ADCMPDR1 registers with results of A/D conversion.
Set the ADCMPLR register while ADCSR.ADST is 0.

Address(es): S12ADC0.ADCMPLR A008 C098h, S12ADC1.ADCMPLR A008 C498h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPL[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPL[15:0]	Compare Level Select	Set the condition for comparison with the selected channels from among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). When Window function is disabled (ADCMPCR.WCMPE bit = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE bit = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W

CMPL[15:0] Bits (Compare Level Select)

The CMPL0[15:0] bits set the condition for use in comparison with the selected channel from among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). A condition can be set for individual comparison of each analog input.
The CMPL[0] bit is used for AN000 (unit 0) and AN100 (unit 1), the CMPL[7] bit is used for AN007 (unit 0) and AN107 (unit 1), and the CMPL[15] bit is used for AN115 (unit 1).
When the result of comparison matches the set condition, ADCMPSR.CMPFn is set to 1 and a compare interrupt (S12CMPI) is generated.
The CMPL[15:8] bits of the unit 0 are reserved. Reading to these bits returns 0. Writing value should be 0.

43.2.20 A/D Compare Level Extended Register (ADCMPLER)

The ADCMPLER register sets the condition for use in comparing the values of ADCMPDR0 and ADCMPDR1 registers with results of A/D conversion.

Set the ADCMPLER register while ADCSR.ADST is 0.

Address(es): S12ADC0.ADCMPLER A008 C093h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPLTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPLTS	Temperature Sensor Output Compare Select	When Window function is disabled (ADCMPCR.WCMPE bit = 0): 0: ADCMPDR0 register value > A/D-converted value 1: ADCMPDR0 register value < A/D-converted value When Window function is enabled (ADCMPCR.WCMPE bit = 1): 0: AD-converted value < ADCMPDR0 register value or A/D-converted value > ADCMPDR1 register value 1: ADCMPDR0 register value < A/D-converted value < ADCMPDR1 register value	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPLTS Bit (Temperature Sensor Output Compare Level Select)

This bit sets the condition for use in comparison with temperature sensor output.

When the result of comparison matches the set condition, ADCMPSER.CMPFTS is set to 1 and a compare interrupt (S12CMPI) is generated.

43.2.21 A/D Compare Data Register y (ADCMPDRy) (y = 0, 1)

Set the reference data for comparison with the selected channels.
This register is accessible even during A/D conversion which allows dynamic changing of the reference data. The ADCMPDR1 register is not used when the Window function is disabled.
The ADCMPDRy register use different formats depending on the following conditions.

- The value of A/D data register format select bit (flush-right or flush-left)
- The value of A/D-conversion accuracy specification bit (12 bits, 10 bits, 8 bits)
- The value of A/D-converted value addition/average mode select register (A/D-converted value addition mode selected and not selected)

(1) When A/D-Converted Value Addition Mode is Not Selected

- The settings for flush-right data with 12-bit accuracy

Address(es): S12ADC0.ADCMPDR0 A008 C09Ch, S12ADC0.ADCMPDR1 A008 C09Eh, S12ADC1.ADCMPDR0 A008 C49Ch, S12ADC1.ADCMPDR1 A008 C49Eh

b15 to b6	CMPD[9:0]	—	10-bit reference value	R/W

43.2.22 A/D Compare Status Register (ADCMPSR)

The ADCMPSR register stores the compare results of compare function.

Address(es): S12ADC0.ADCMPSR A008 C0A0h, S12ADC1.ADCMPSR A008 C4A0h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	CMPF[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	CMPF[15:0]	Compare Flag	Indicates compare results of AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). 0: Condition for comparison was not met. 1: Condition for comparison was met.	R/W

CMPF[15:0] Bits (Compare Flag)

These bits are status flags to indicate the results of comparison with the selected analog inputs from among AN000 to AN007 (unit 0) and AN100 to AN115 (unit 1). When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLR.CMPLn, the corresponding flags are set to 1.

When the ADCMPCR.CMPIE bit is 1, a compare interrupt (S12CMPI) request is generated when the setting of the flag becomes 1.

The CMPF[0] bit is used for AN000 (unit 0)/AN100 (unit 1), the CMPF[7] bit is used for AN007 (unit 0)/AN107 (unit 1), and the CMPF[15] bit is used for AN115 (unit 1).

The value 1 cannot be written to the CMPFn bit.

The CMPF[15:8] bits of the unit 0 are reserved. Reading to these bits returns 0. Writing value should be 0.

[Setting condition]

- The condition set in ADCMPLR.CMPLn is met.

[Clearing condition]

- 0 is written after reading 1.

43.2.23 A/D Compare Status Extended Register (ADCMPSER)

The ADCMPSER register is a status register that indicates the compare results of temperature sensor output.

Address(es): S12ADC0.ADCMPSER A008 C0A4h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	CMPFTS
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	CMPFTS	Temperature Sensor Output Compare Flag	0: Condition for comparison was not met. 1: Condition for comparison was met.	R/W
b7 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

CMPFTS Bit (Temperature Sensor Output Compare Flag)

This bit is a status flag to indicate the result of comparison with temperature sensor output. When the result of comparison on completion of A/D conversion matches the condition set in ADCMPLER.CMPLTS, this flag is set to 1. When the ADCMPCR.CMPIE bit is 1, a compare interrupt (S12CMPI) request is generated when the setting of the flag becomes 1.

The value 1 cannot be written to the CMPFTS bit.

[Setting condition]

- The condition set in ADCMPLER.CMPLTS is met.

[Clearing condition]

- 0 is written after reading 1.

43.2.24 A/D Pin-Level Self-Diagnosis Control Register (ADTDCR)

ADTDCR controls pin-level self-diagnosis function. For details about this function, see section 43.3.13 Pin-Level Self-Diagnosis Function.

Address(es): S12ADC0.ADTDCR A008 C0C8h, S12ADC1.ADTDCR A008 C4C8h

	b7	b6	b5	b4	b3	b2	b1	b0
	TDE	—	—	—	—	—	TDLV[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	TDLV[1:0]	Pin-level Self-diagnosis Level Select	b1 b0 0 0: Input channels with even numbers are discharged to AVSS, and input channels with odd numbers are charged to AVCC. 0 1: Input channels with even numbers are charged to AVCC, and input channels with odd numbers are discharged to AVSS. 1 0: Input channels with even numbers are discharged to AVSS, and input channels with odd numbers are charged to AVCC × 1/2. 1 1: Input channels with even numbers are charged to AVCC × 1/2, and input channels with odd numbers are discharged to AVSS.	R/W
b6 to b2	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TDE	Pin-level Self-diagnosis Enable	0: Disables pin-level self-diagnosis. 1: Enables pin-level self-diagnosis.	R/W

TDLV[1:0] Bits (Pin-level Self-diagnosis Level Select)

These bits select the pin level for pin-level self-diagnosis.
Set the TDLV[1:0] bits while ADCSR.ADST bit is 0.

TDE Bit (Pin-level Self-diagnosis Enable)

This bit selects whether to perform pin-level self-diagnosis.
Set the TDE bit while ADCSR.ADST bit is 0.

43.2.25 A/D Error Control Register (ADERCR)

ADERCR controls error detection function. For details about errors, see section 43.3.14 Error Detection Function.

Address(es): S12ADC0.ADERCR A008 C0CAh, S12ADC1.ADERCR A008 C4CAh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	OWEIE	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b2	OWEIE	Overwrite Error Interrupt Enable	0: Disables interrupt generation when an overwrite error is detected. 1: Enables interrupt generation when an overwrite error is detected.	R/W
b7 to b3	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

OWEIE Bit (Overwrite Error Interrupt Enable)

This bit sets whether to enable or disable generation of an error interrupt request (S12ADE) when an overwrite error is detected.

Set the OWEIE bit while ADCSR.ADST bit is 0.

43.2.26 A/D Error Clear Register (ADERCLR)

The A/D error clear register is a write-only register for clearing errors.

Address(es): S12ADC0.ADERCLR A008 C0CBh, S12ADC1.ADERCLR A008 C4CBh

	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	OWEC	—	—
Value after reset:	0	0	0	0	0	0	0	0

b1, b0	—	Reserved	The write value should be 0.	W
b2	OWEC	Overwrite Error Clear	Writing 0: Disables clearing overwrite errors. Writing 1: Enables clearing overwrite errors.	W
b7 to b3	—	Reserved	The write value should be 0.	W

43.2.27 A/D Overwrite Error Register (ADOWER)

The ADOWER register is a status register that indicates that the results of A/D conversion in the ADDRy register were not read and an overwrite occurred.

Address(es): S12ADC0.ADOWER A008 C0D2h, S12ADC1.ADOWER A008 C4D2h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	OWE[15:0]															
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b15 to b0	OWE[15:0]	Overwrite Error	0: No overwrite error occurred in S12ADC0.ADDR0 to S12ADC0.ADDR7 (unit 0) and S12ADC1.ADDR0 to S12ADC1.ADDR15 (unit 1). 1: An overwrite error occurred in S12ADC0.ADDR0 to S12ADC0.ADDR7 (unit 0) and S12ADC1.ADDR0 to S12ADC1.ADDR15 (unit 1).	R

OWE[15:0] Bits (Overwrite Error 0)

The OWE[15:0] bits are set to 1 when the results of the next A/D conversion are stored in the ADDRy register after the A/D conversion finishes without the results of A/D conversion in the ADDRy register being read.

The OWE[15:0] bits are cleared to 0 when 1 is written to the ADERCLR.OWEC register. The OWE[15:0] bits cannot be written to 1.

The OWE[0] bit corresponds to S12ADC0.ADDR0 and the OWE[7] bit corresponds to S12ADC0.ADDR7 for unit 0.

The OWE[0] bit corresponds to S12ADC1.ADDR0 and the OWE[15] bit corresponds to S12ADC1.ADDR15 for unit 1.

43.2.28 A/D Overwrite Error Extended Register (ADOWEER)

The ADOWEER register is a status register that indicates that the results of A/D conversion in the ADDBLDRB, ADDBLDRA, ADDBLDR, ADRD, ADTSDR registers were not read and an overwrite occurred.

Address(es): S12ADC0.ADOWEER A008 C0D6h, S12ADC1.ADOWEER A008 C4D6h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	DBOWE	A/D Data Duplication Register B Overwrite Error	0: No overwrite error occurred in ADDBLDRB. 1: An overwrite error occurred in ADDBLDRB.	R
b1	DAOWE	A/D Data Duplication Register A Overwrite Error	0: No overwrite error occurred in ADDBLDRA. 1: An overwrite error occurred in ADDBLDRA.	R
b2	DOWE	A/D Data Duplication Register Overwrite Error	0: No overwrite error occurred in ADDBLDR. 1: An overwrite error occurred in ADDBLDR.	R
b3	DIAGOWE	A/D Self-diagnosis Data Register Overwrite Error	0: No overwrite error occurred in ADRD. 1: An overwrite error occurred in ADRD.	R
b4	TSOWE	A/D Temperature Sensor Data Register Overwrite Error	0: No overwrite error occurred in ADTSDR. 1: An overwrite error occurred in ADTSDR.	R
b15 to b5	—	Reserved	These bits are read as 0.	R

DBOWE Bit (A/D Data Duplication Register B Overwrite Error)

DBOWE bit is set to 1 when the results of the next A/D conversion are stored in the ADDBLDRB register after the A/D conversion finishes without the results of A/D conversion in the ADDBLDRB register being read.
DBOWE bit is cleared to 0 when 1 is written to the ADERCLR.OWEC register. DBOWE bit cannot be written to 1.

DAOWE Bit (A/D Data Duplication Register A Overwrite Error)

DAOWE bit is set to 1 when the results of the next A/D conversion are stored in the ADDBLDRA register after the A/D conversion finishes without the results of A/D conversion in the ADDBLDRA register being read.
DAOWE bit is cleared to 0 when 1 is written to the ADERCLR.OWEC register. DAOWE bit cannot be written to 1.

DOWE Bit (A/D Data Duplication Register Overwrite Error)

DOWE bit is set to 1 when the results of the next A/D conversion are stored in the ADDBLDR register after the A/D conversion finishes without the results of A/D conversion in the ADDBLDR register being read.
DOWE bit is cleared to 0 when 1 is written to the ADERCLR.OWEC register. DOWE bit cannot be written to 1.

DIAGOWE Bit (A/D Self-diagnosis Data Register Overwrite Error)

DIAGOWE bit is set to 1 when the results of the next A/D conversion are stored in the ADRD register after the A/D conversion finishes without the results of A/D conversion in the ADRD register being read.
DIAGOWE bit is cleared to 0 when 1 is written to the ADERCLR.OWEC register. DIAGOWE bit cannot be written to 1.

TSOWE Bit (A/D Temperature Sensor Data Register Overwrite Error)

TSOWE bit is set to 1 when the results of the next A/D conversion are stored in the ADTSDR register after the A/D conversion finishes without the results of A/D conversion in the ADTSDR register being read.
TSOWE bit is cleared to 0 when 1 is written to the ADERCLR.OWEC register. TSOWE bit cannot be written to 1.

43.3 Operation

43.3.1 Scanning Operation

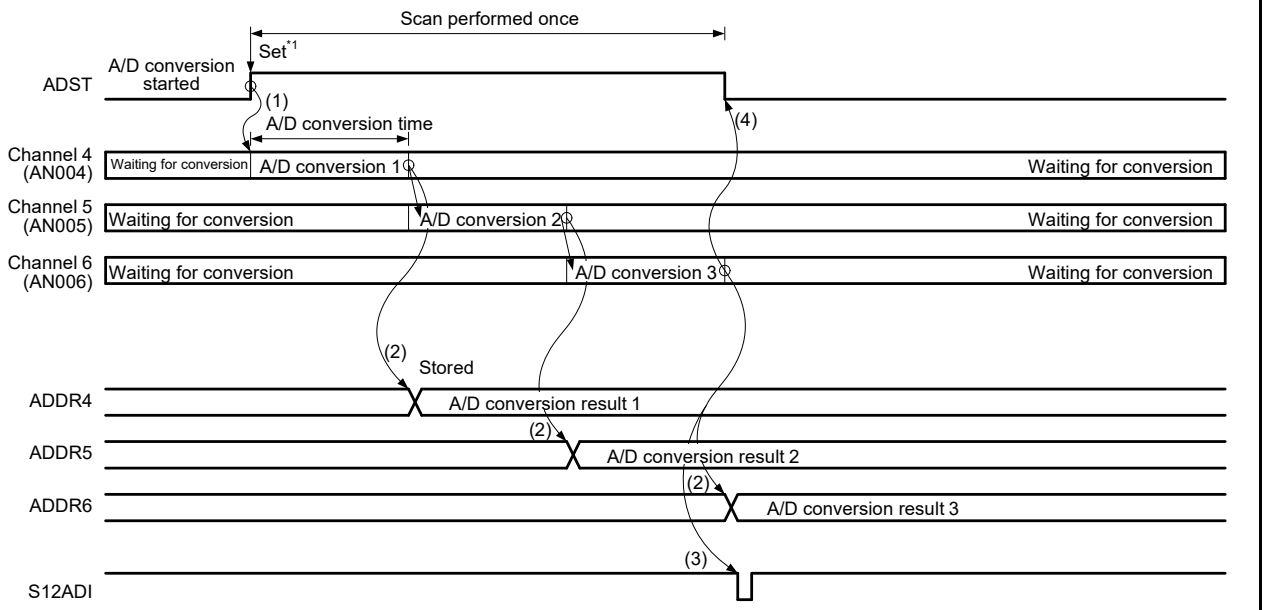
In scanning, A/D conversion is performed sequentially on the analog inputs of the specified channels.
There are three operating modes: single scan mode, continuous scan mode, and group scan mode. In single scan mode, one or more specified channels are scanned once. In continuous scan mode, one or more specified channels are scanned repeatedly until the ADST bit in ADCSR is cleared to 0 from 1. In group scan mode, the selected channels of group A and the selected channels of group B are scanned once after starting to be scanned according to the respective synchronous triggers (MTU3a, GPTa, TPUa, ELC).
In single scan mode and continuous scan mode, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the pin with the smallest number n. In group scan mode, A/D conversion is performed for ANn pins selected by the ADANSA register for group A, and performed for ANn pins selected by the ADANSB register for group B, respectively, starting from the pin with the smallest number n.
When self-diagnosis is selected, it is executed once at the beginning of each scan and one of the three voltages internally generated in the 12-bit A/D converter is converted.
The temperature sensor output can be scanned at the same time as the analog input of channels, and A/D conversion of the analog input of channels and the temperature sensor output is performed in that order.
When the extended analog input is selected, A/D conversion should be performed in single scan mode or continuous scan mode.
Double trigger mode is to be used with single scan mode or group scan mode. With double trigger mode being enabled, A/D conversion data of a channel selected by the DBLANS[4:0] bits in ADCSR is duplicated only if the conversion is started by any of the synchronous triggers (MTU3a, GPTa, TPUa, ELC) selected by the TRSA[5:0] bits in ADSTRGR.
To enable double trigger extended mode, select double trigger mode, and then select the synchronous trigger TRGnAN or TRGnBN (n = 4, 7), or GTADTRAmN or GTADTRBmN (m = 0 to 3) as the trigger for starting A/D conversion. In double trigger extended mode, in addition to the usual double trigger mode operation, the A/D conversion data is stored in the A/D data duplication register A (ADDBLDRA) or A/D data duplication register B (ADDBLDRB), depending on the selected trigger.
If two types of trigger sources (TRGnAN and TRGnBN (n = 4, 7), or GTADTRAmN and GTADTRBmN (m = 0 to 3)) occur at the same time, the A/D conversion data is stored in the data duplication register B (ADDBLDRB), instead of the data being sorted by the trigger source. If a new trigger is input during A/D conversion caused by another trigger, the former new trigger is ignored.
When any of AN000 to AN003 channels is set for a channel-dedicated sample-and-hold circuit by the SHANS[3:0] bits in ADSHCR, the target analog input specified is sampled and held before the first A/D conversion of each scan.

43.3.2 Single Scan Mode

43.3.2.1 Basic Operation (without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of single scan mode, A/D conversion is performed once on the analog input of the specified channels as below.

(1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the pin with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion is enabled).
(4) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



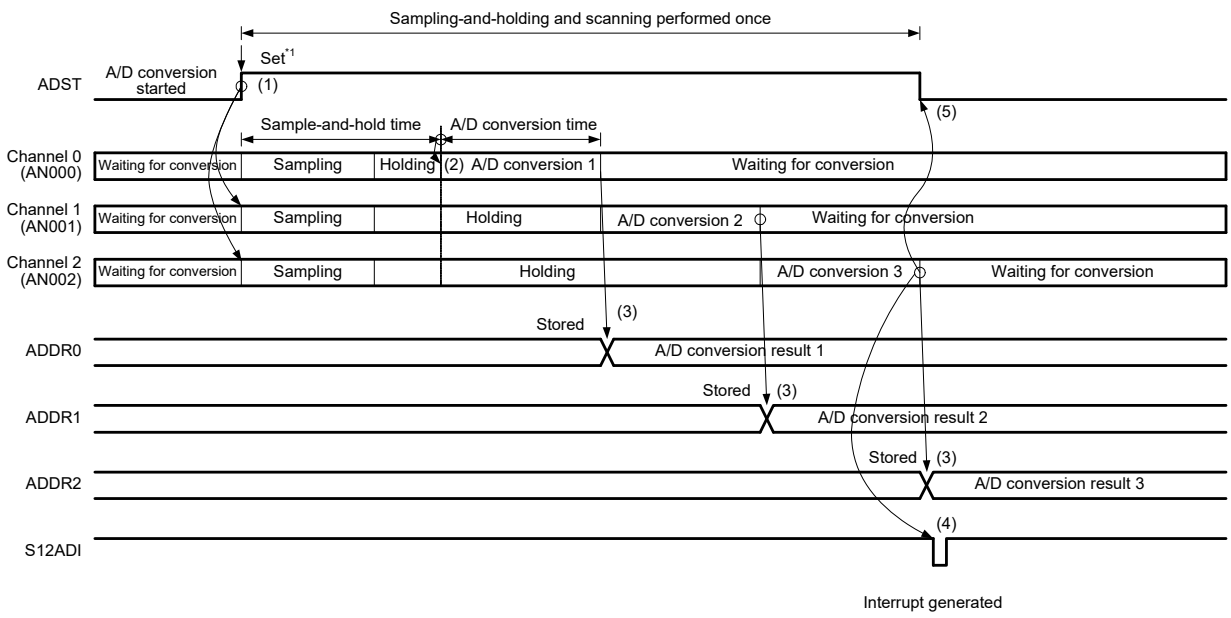
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.4 Example of Operation in Single Scan Mode (Basic Operation: AN004 to AN006 Selected)

43.3.2.2 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits)

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is performed once on the analog input of all the selected channels as below. The channels whose channel-dedicated sample-and-hold circuit is to be used can be selected by the SHANS[3:0] bits in ADSHCR.

(1) Analog input sampling of all the channels whose channel-dedicated sample-and-hold circuit is to be used is started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input.
(2) After sample-and-hold operation, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion is enabled).
(5) The ADST bit in ADCSR remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



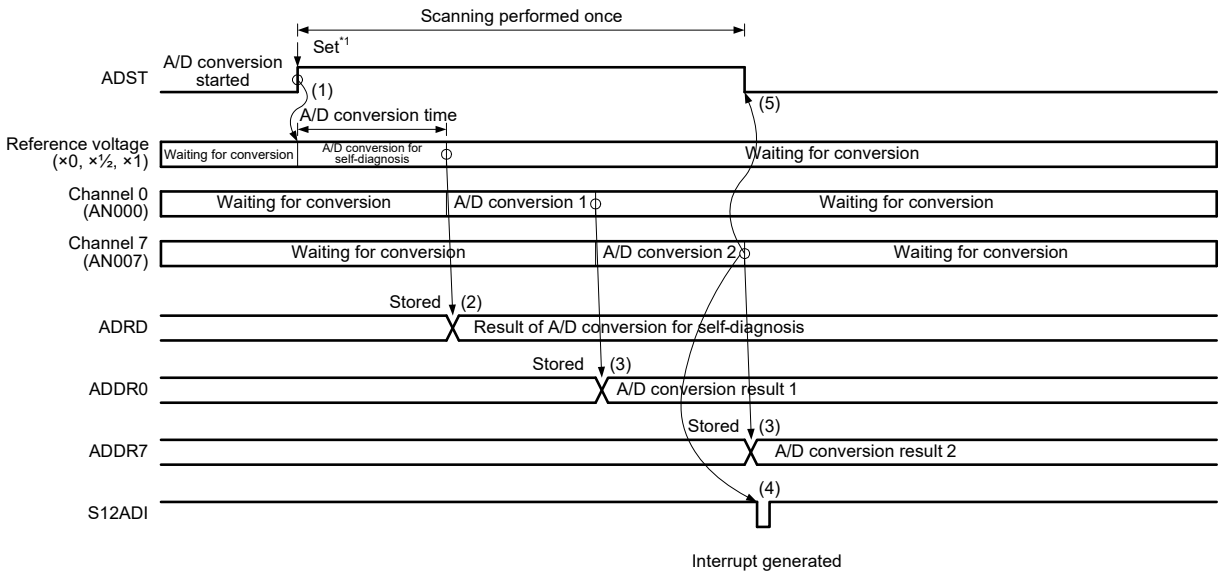
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.5 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used: AN000 to AN002 Selected)

43.3.2.3 Channel Selection and Self-Diagnosis (without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected, A/D conversion is first performed for the reference voltage VREFH0 (unit 0) or VREFH1 (unit 1) (reference voltage ×0, ×1/2, or ×1) supplied to the A/D converter, and then A/D conversion is performed once on the analog input of the selected channels as below.

(1) A/D conversion for self-diagnosis is first started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input.
(2) When A/D conversion for self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion enabled).
(5) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



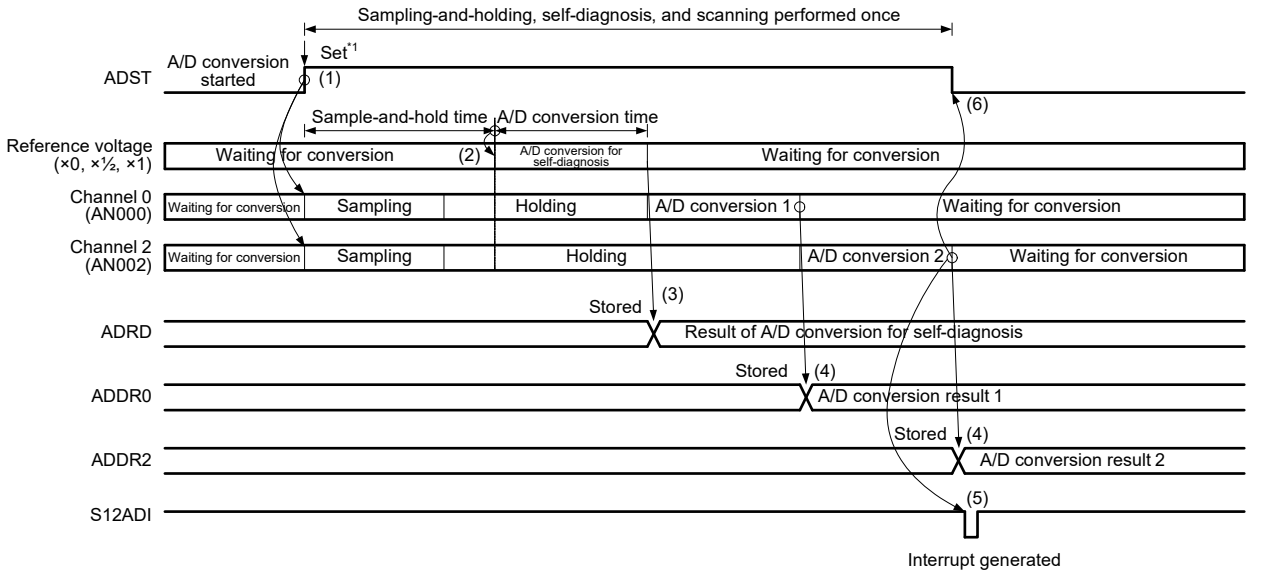
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.6 Example of Operation in Single Scan Mode (Basic Operation: AN000 and AN007 Selected + Self-Diagnosis)

43.3.2.4 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits)

When the channel-dedicated sample-and-hold circuit is used and channels and self-diagnosis are selected, sample-and-hold operation is first performed, and then A/D conversion is performed once for the reference voltage VREFH0 (unit 0) or VREFH1 (unit 1) (reference voltage ×0, ×1/2, or ×1) supplied to the 12-bit A/D converter as below. After that, A/D conversion is performed only once on the analog input of the selected channels. The ADSHCR.SHANS[3:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuit is used.

(1) Analog input sampling of all the channels whose channel-dedicated sample-and-hold circuit is to be used is started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input.
(2) After sample-and-hold operation, A/D conversion is started by self-diagnosis.
(3) When A/D conversion due to self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(5) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion enabled).
(6) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



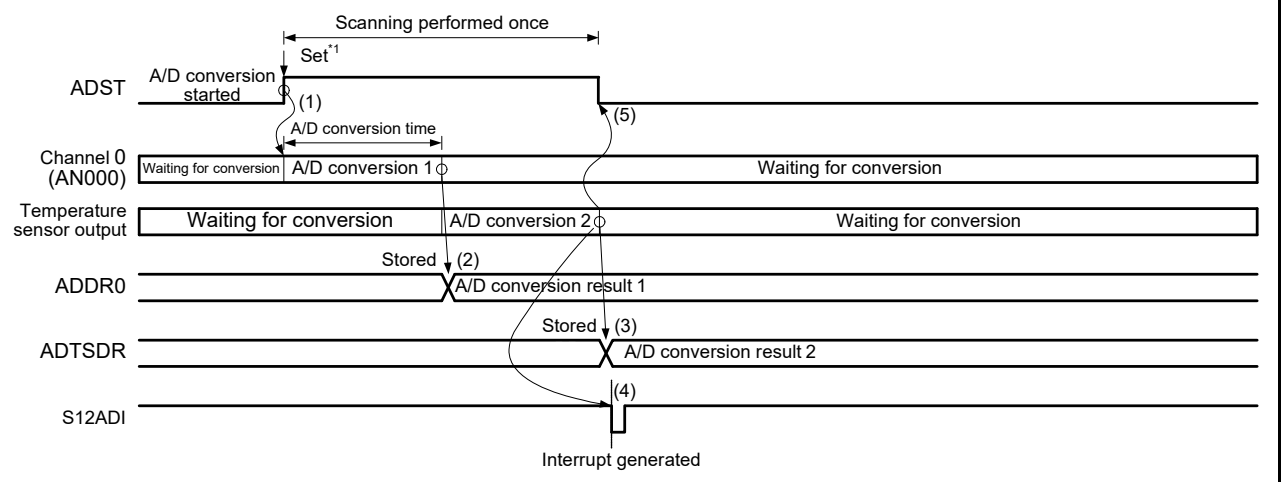
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.7 Example of Operation in Single Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000 and AN002 Selected + Self-Diagnosis)

43.3.2.5 A/D Conversion of Temperature Sensor Output

When the channels and temperature sensor output are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then A/D conversion is performed once on the temperature sensor output as below.
With the channels deselected, selecting only the temperature sensor output is also possible.

(1) When software, synchronous trigger (MTU3a, GPTa, TPUa, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn pins selected in the ADANSA register starts in order from the channel with the lowest number n.
(2) On completion of A/D conversion on the channel, the result is stored in the corresponding A/D data register (ADDRy), and then A/D conversion of temperature sensor output starts.
(3) On completion of A/D conversion of temperature sensor output, the result is stored in the corresponding A/D temperature sensor data register (ADTRDR).
(4) If the ADCSR.ADIE bit is set to 1 (enabling S12ADI0 interrupt generation upon scan conversion completion), an S12ADI interrupt is generated.
(5) The ADCSR.ADST bit remains 1 (starting A/D conversion) during A/D conversion, and is automatically cleared to 0 upon completion of A/D conversion. Then the 12-bit A/D converter enters a waiting state.



Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.8 Example of Operation in Single Scan Mode (Basic Operation: AN000 and Temperature Sensor Output Selected)

43.3.2.6 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in single scan mode, A/D conversion is performed for two rounds of single scan operation started by a synchronous trigger (MTU3a, GPTa, TPUa, ELC) as a sequence as shown below.
The temperature sensor output A/D conversion select bits (ADEXICR.TSSA and ADEXICR.TSSB) should be set to 0.
Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR and setting the DBLE bit in ADCSR to 1. When the DBLE bit in ADCSR is set to 1, channel selection using the ADANSA register is invalid. In double trigger mode, a synchronous trigger (MTU3a, GPTa, TPUa, ELC) should be selected using the TRSA[5:0] bits in ADSTRGR; the EXTRG bit and TRGE bit in ADCSR should be set to 0 and 1, respectively. Software trigger should not be used.

(1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), A/D conversion is started on the single channel selected by the DBLANS[4:0] bits in ADCSR.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) The ADST bit in ADCSR is automatically cleared to 0 and the 12-bit A/D converter enters a waiting state. Here, an S12ADI interrupt request is not generated irrespective of the ADIE (S12ADI interrupt upon scanning completion enabled) bit setting in ADCSR.
(4) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by the second synchronous trigger input, A/D conversion is started on the single channel selected by the DBLANS[4:0] bits in ADCSR.
(5) When A/D conversion is completed, the A/D conversion result is stored into the A/D data duplication register (ADDBLDR), which is exclusively used in double trigger mode.
(6) If the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion enabled), an S12ADI interrupt is generated.
(7) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion is completed. Then the 12-bit A/D converter enters a waiting state.

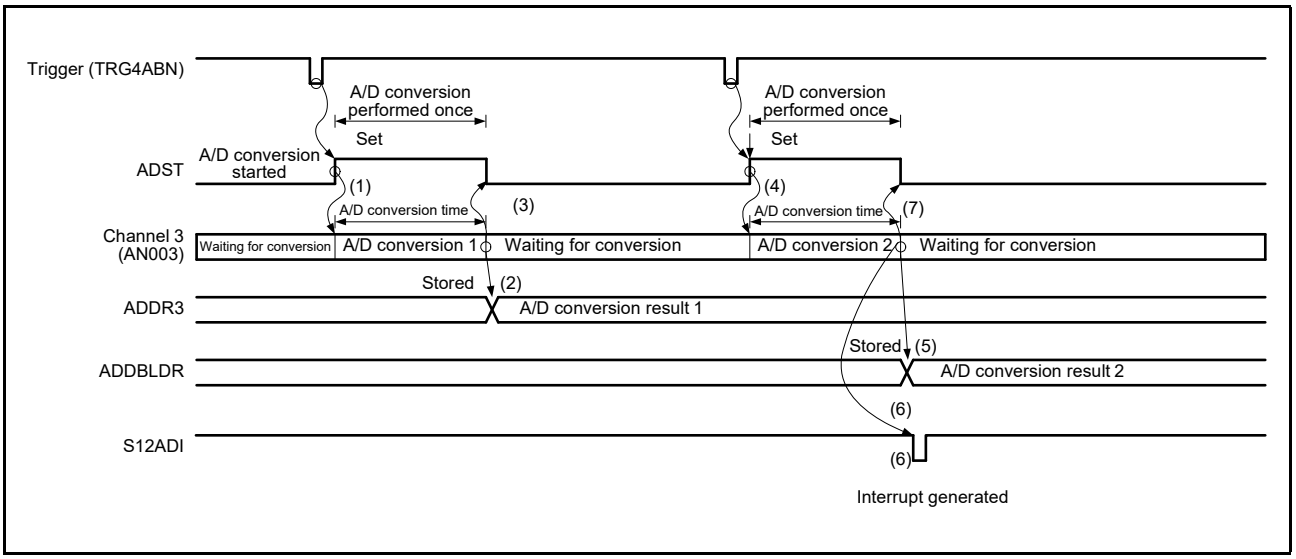


Figure 43.9 Example of Operation in Single Scan Mode (Double Trigger Mode Selected: AN003 Duplicated; TRG4ABN Selected as Trigger; Self-Diagnosis Deselected)

43.3.2.7 Extended Operations When Double Trigger Mode is Selected

When double trigger mode is selected in single scan mode, and a synchronous trigger TRGnAN or TRGnBN (n = 4, 7) is selected as the trigger for the start of A/D conversion (the ADSTRGR.TRSA[5:0] bits are set to 0Bh or 0Fh), or GTADTRAmN or GTADTRBmN (m = 0 to 3) is selected (the ADSTRGR.TRSA[5:0] bits are set to 19h, 1Ah, 1Bh, or 1Ch), the following operations are included with the operations described when double trigger mode is selected.
When A/D conversion is started by a synchronous trigger A (TRGnAN; n = 4, 7, or GTADTRAmN; m = 0 to 3), the results of A/D conversion are stored in A/D data duplication register A (ADDBLDRA). Furthermore, when A/D conversion is started by a synchronous trigger B (TRGnBN; n = 4, 7) or GTADTRBmN (m = 0 to 3), the results of A/D conversion are stored in A/D data duplication register B (ADDBLDRB). With the correspondence between synchronous trigger sources and registers for data storage determined in this way, the target register for storing the results of A/D conversion does not depend on the order of trigger input. Results of A/D conversion are also stored in the A/D data register (ADDRy) and the A/D data duplication register (ADDBLDR) at the same time, and this depends on the order of trigger input.
In extended double trigger mode, if two types of triggers have occurred simultaneously with TRGnAN or TRGnBN (n = 4, 7) or GTADTRAmN or GTADTRBmN (m = 0 to 3) selected, results are not sorted by the trigger sources and are stored in A/D data duplication register B (ADDBLDRB).
Note that if a new trigger source is input during A/D conversion caused by another trigger source, the former new trigger source is ignored and sorting is performed by the latter trigger source.

The extended operations in double trigger mode when the first trigger is TRG4AN with the synchronous trigger TRG4AN or TRG4BN selected as the trigger for the start of A/D conversion are performed as follows.

(1) A/D conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the TRG4AN input sets the ADCSR.ADST bit to 1 (starting A/D conversion).
(2) The result is stored in A/D data-duplication register A (ADDBLDRA) and in the corresponding A/D data register (ADDRy) on completion of the A/D conversion for the channel.
(3) The ADST bit is automatically cleared and the A/D converter enters the waiting state. An S12ADI interrupt is not generated at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI interrupts in response to scan completion).
(4) When the TRG4BN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
(5) The result is stored in A/D data-duplication register B (ADDBLDRB) and in the A/D data-duplication register (ADDBLDR) on completion of A/D conversion.
(6) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
(7) The ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the A/D converter enters the waiting state.

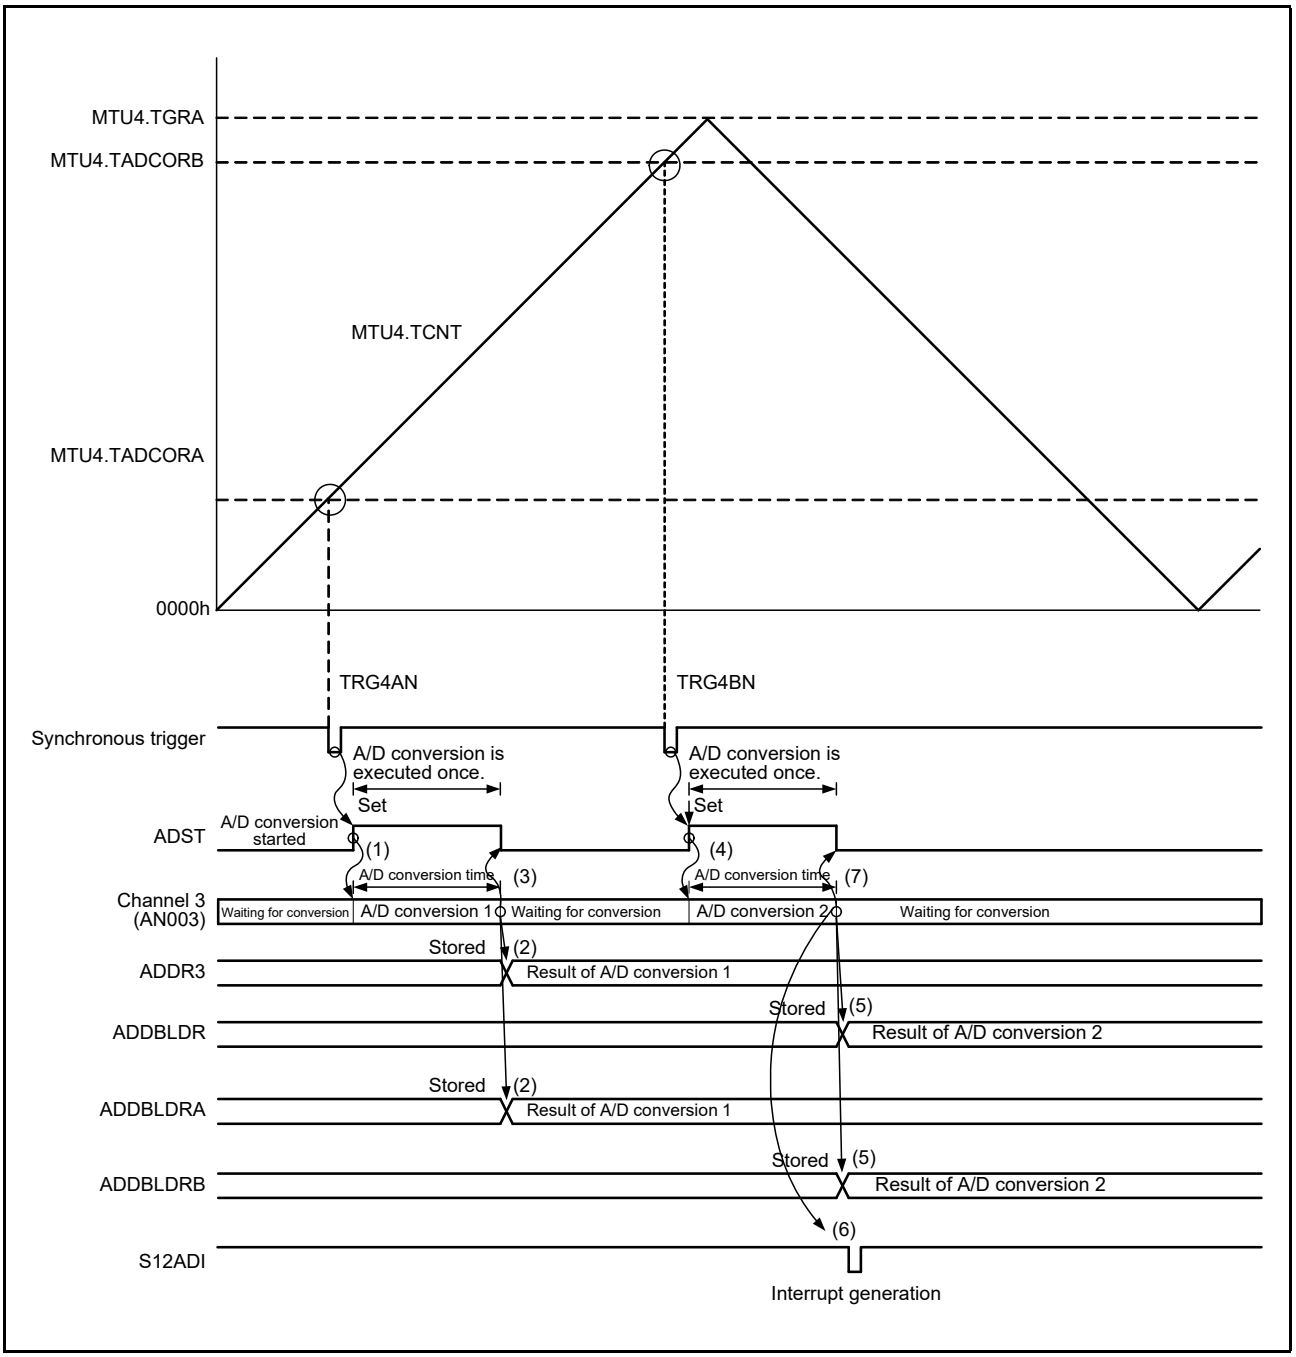

Figure 43.10 Example of Extended Operation in Double Trigger Mode (1)
(Duplication Selected for AN003, TRG4AN or TRG4BN Selected, First Trigger is TRG4AN)

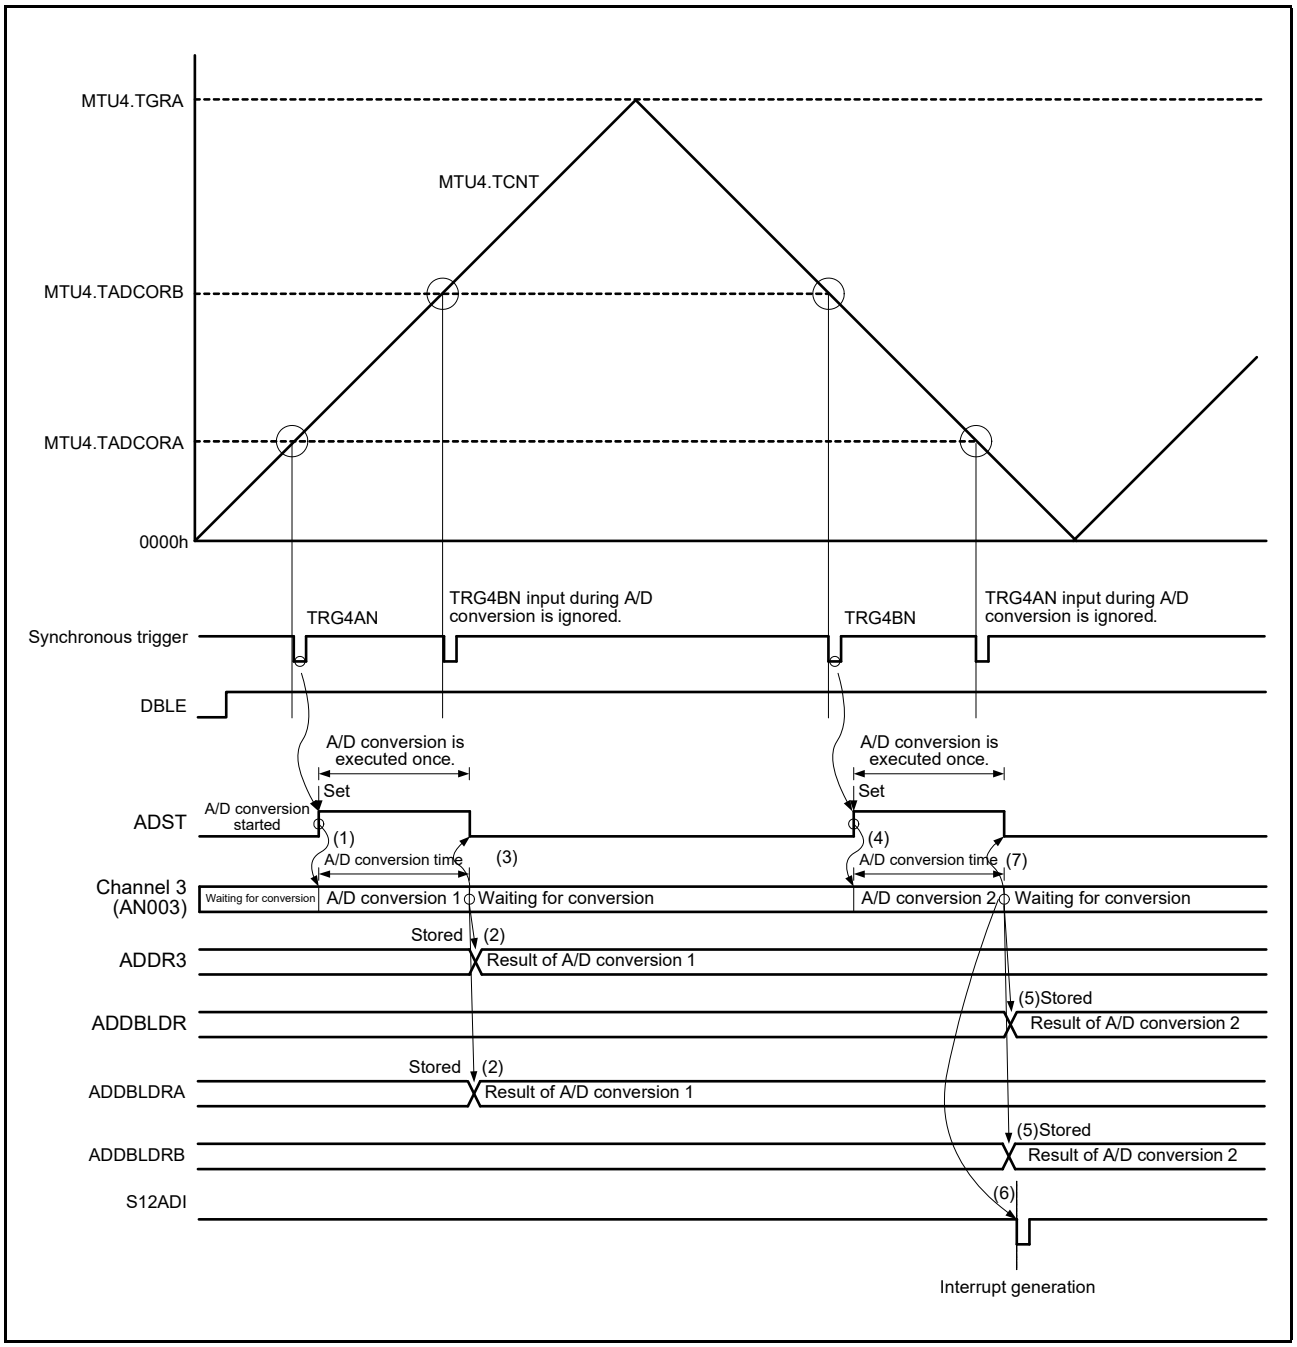

Figure 43.11 Example of Extended Operation in Double Trigger Mode (2)
(Duplication Selected for AN003, TRG4AN and TRG4BN Selected, First Trigger is TRG4AN)

The following describes the extended operations in double trigger mode in response to TRG4BN as the first trigger, again in the case where TRG4AN or TRG4BN is selected as the synchronous trigger for the start of A/D conversion.

(1) When the TRG4BN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
(2) On completion of A/D conversion, the result is stored in A/D data duplication register B (ADDBLDRB) and in the corresponding A/D data register (ADDRy).
(3) ADST is automatically cleared and the 12-bit A/D converter enters the waiting state. An S12ADI interrupt is not generated at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI interrupts in response to scan completion).
(4) When the TRG4AN input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the single channel selected by the ADCSR.DBLANS[4:0] bits starts.
(5) On completion of A/D conversion, the result is stored in A/D data duplication register A (ADDBLDRA) and in the A/D data duplication register (ADDBLDR).
(6) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(7) The ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is cleared on completion of conversion, after which the 12-bit A/D converter enters the waiting state.

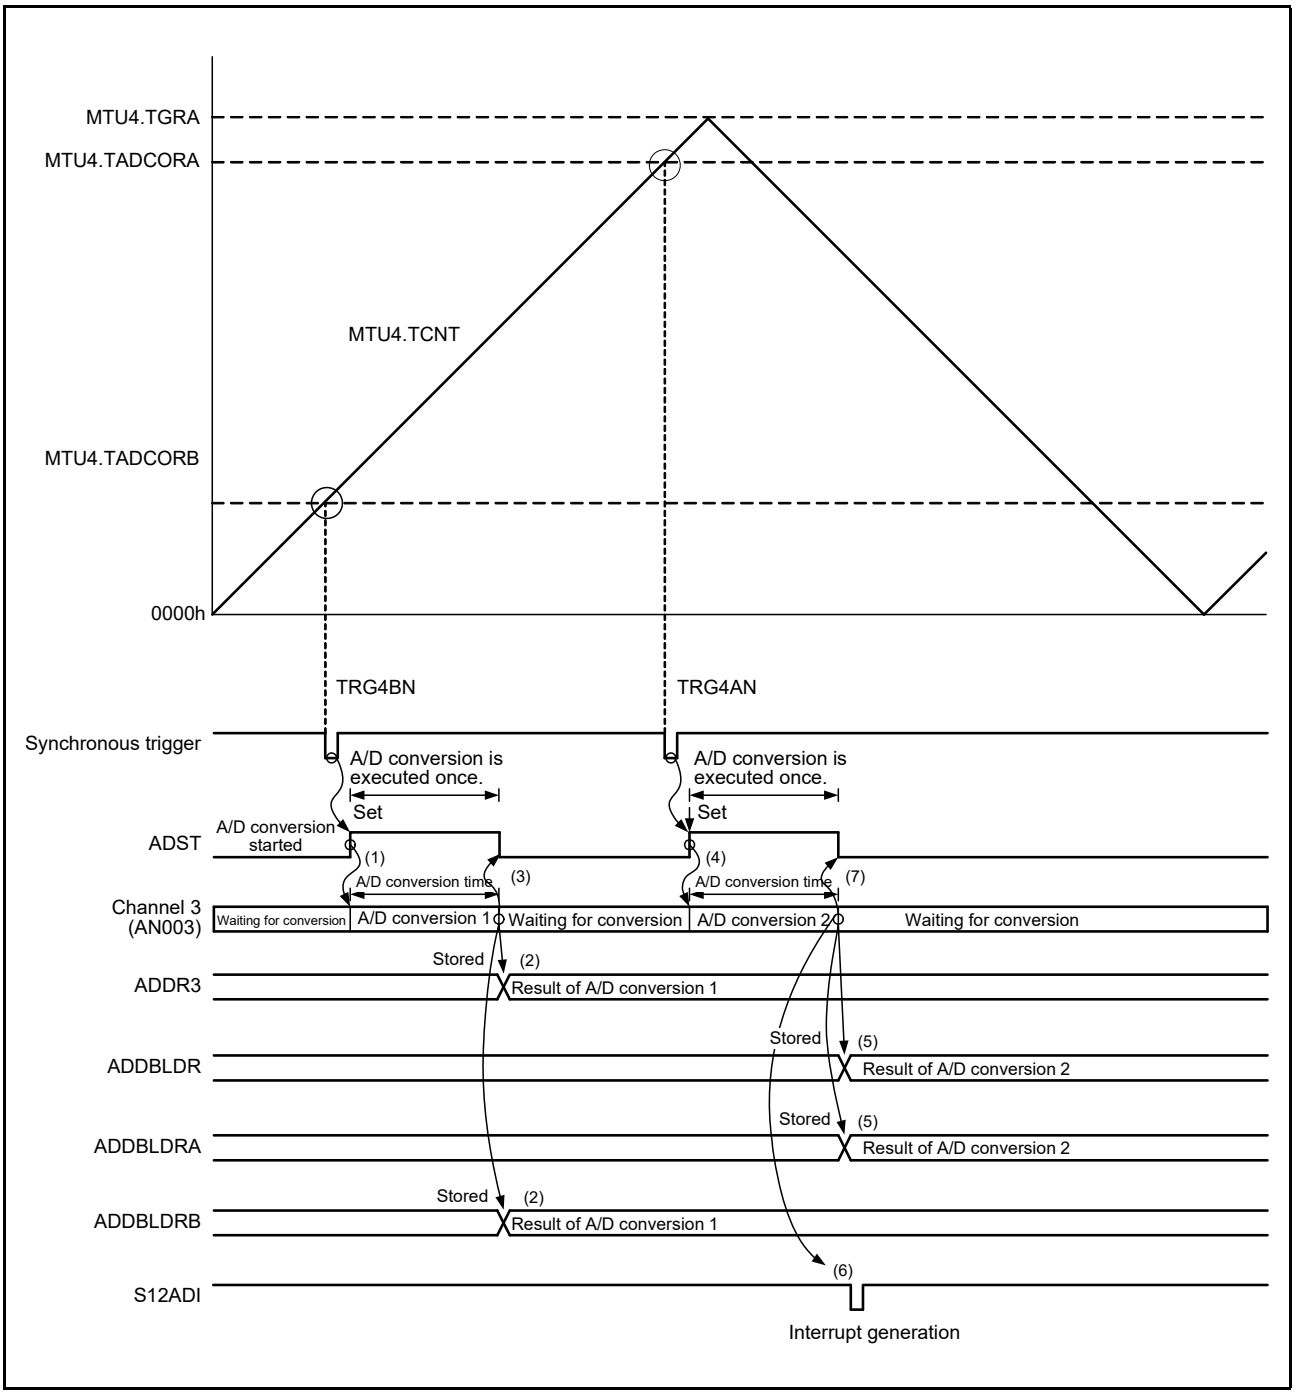

Figure 43.12 Example of Extended Operation in Double Trigger Mode (3)
(Duplication Selected for AN003, TRG4AN and TRG4BN Selected, First Trigger is TRG4BN)

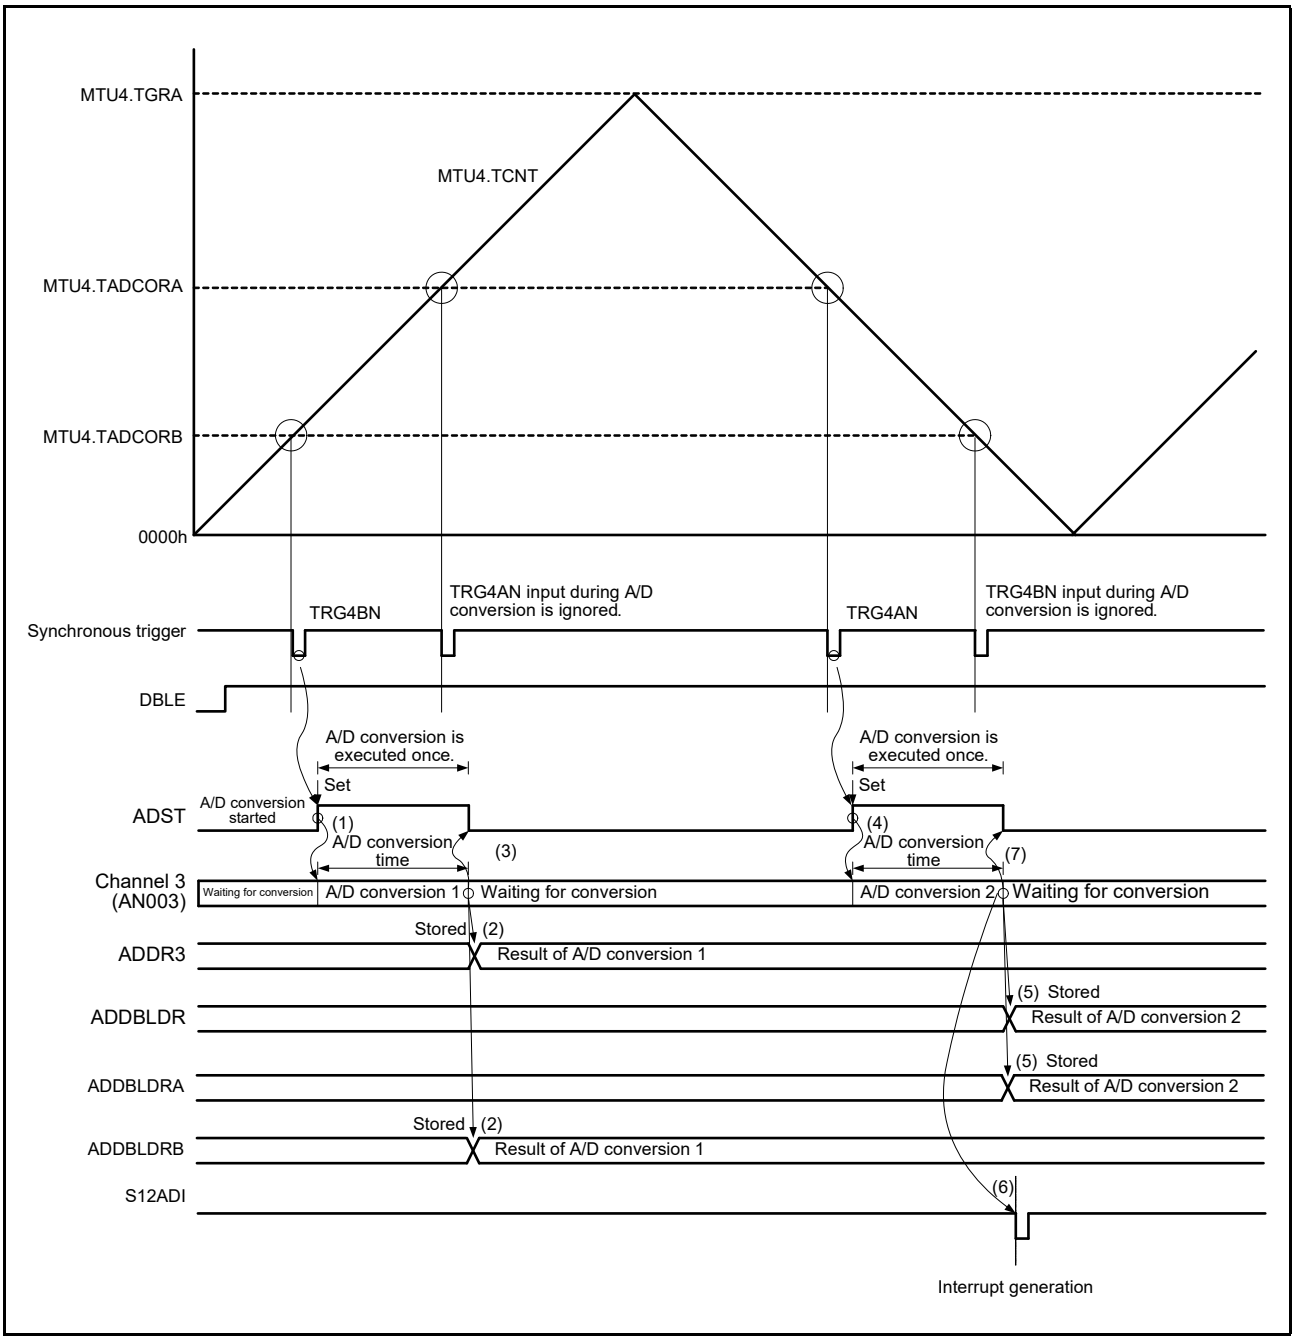

Figure 43.13 Example of Extended Operation in Double Trigger Mode (4)
(Duplication Selected for AN003, TRG4AN and TRG4BN Selected, First Trigger is TRG4BN)

The followings are the extended operations in double trigger mode performed when two types of trigger sources simultaneously occur with the synchronous trigger GTADTRA0N or GTADTRB0N selected as an A/D conversion start trigger.

(1) The first A/D conversion on the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the first simultaneous input of the two trigger sources GTADTRA0N and GTADTRB0N sets the ADCSR.ADST bit to 1 (starting A/D conversion).
(2) The result is stored in A/D data duplication register B (ADDBLDRB) and in the corresponding A/D data register (ADDRy) on completion of the A/D conversion on the channel.
(3) The ADST bit is automatically cleared and the 12-bit A/D converter enters the waiting state. An S12ADI interrupt is not generated at this time, regardless of the setting of the ADCSR.ADIE bit (i.e. whether or not this is set to enable S12ADI interrupts in response to scan completion).
(4) The second A/D conversion on the single channel selected by the ADCSR.DBLANS[4:0] bits starts when the second simultaneous input of the two trigger sources GTADTRA0N and GTADTRB0N sets the ADCSR.ADST bit to 1 (starting A/D conversion).
(5) The result is stored in A/D data duplication register B (ADDBLDRB) and in A/D data duplication register (ADDBLDR) on completion of the A/D conversion.
(6) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (enabling S12ADI interrupt due to completion of the scan).
(7) The ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is cleared on completion of conversion, after which the 12-bit A/D converter enters the waiting state.

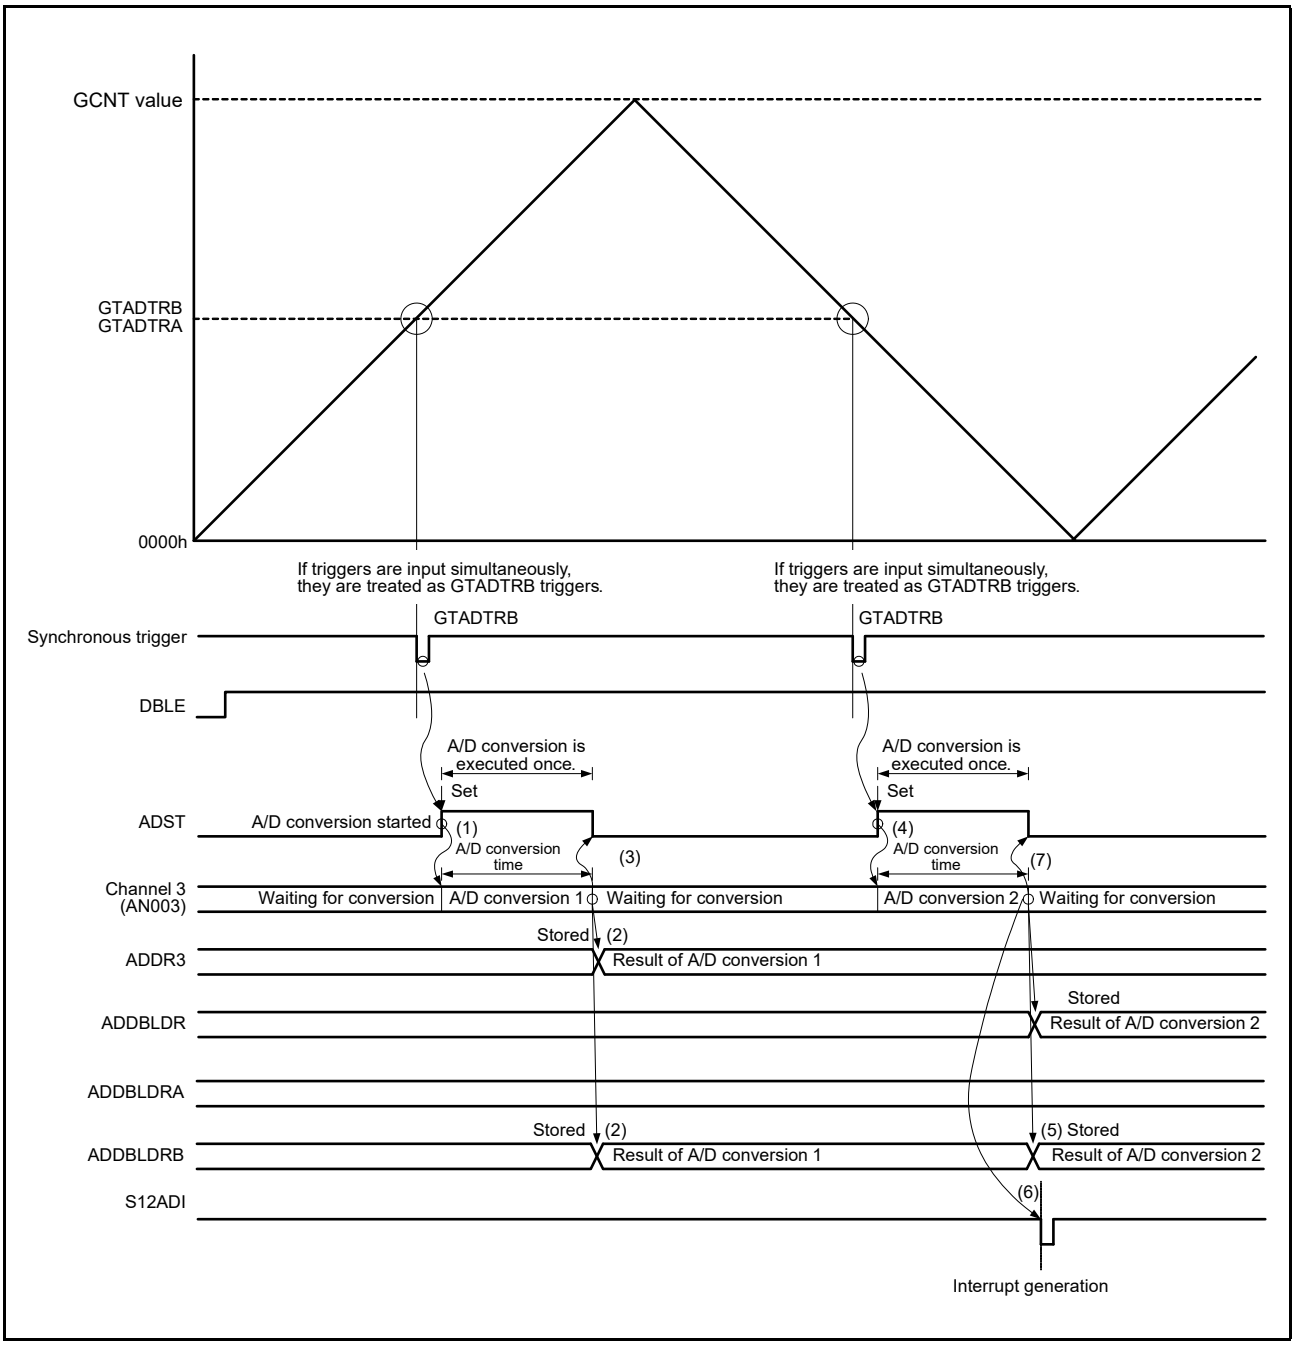

Figure 43.14 Example of Extended Operation in Double Trigger Mode (5) (Duplication Selected for AN003, GTADTRA0N and GTADTRB0N Selected, Two Trigger Sources Simultaneously Occurred)

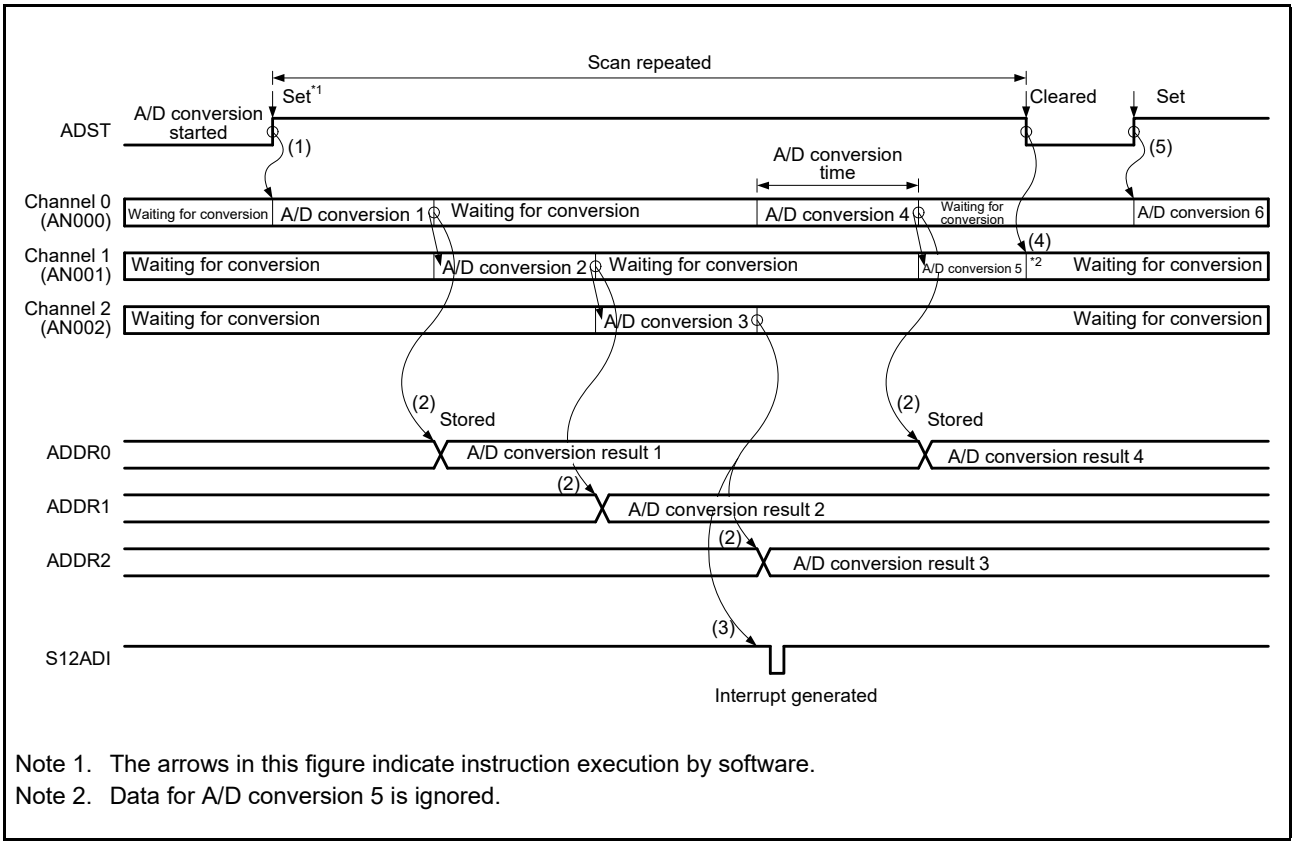
43.3.3 Continuous Scan Mode

43.3.3.1 Basic Operation (without Channel-Dedicated Sample-and-Hold Circuits)

In basic operation of continuous scan mode, A/D conversion is performed repeatedly on the analog input of the channels selected by the ADANSA register as below.

(1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled).
The 12-bit A/D converter sequentially starts A/D conversion for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(4) The ADST bit in ADCSR is not automatically cleared and steps 2 and 3 are repeated as long as the bit remains 1 (A/ D conversion start). When the ADCSR.ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(5) When the ADST bit is later set to 1 (A/D conversion start), A/D conversion is started again for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.



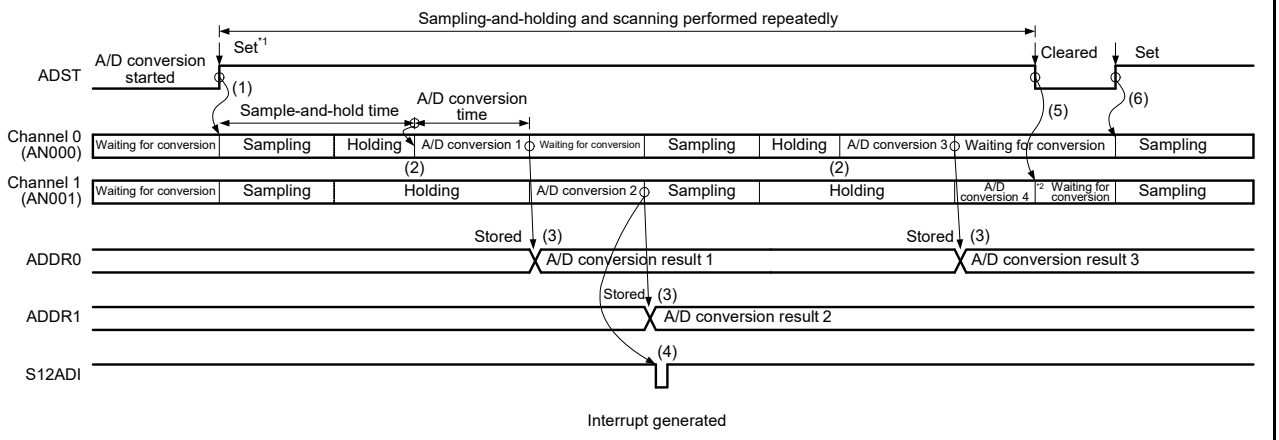
Note 1. The arrows in this figure indicate instruction execution by software.
Note 2. Data for A/D conversion 5 is ignored.

Figure 43.15 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 to AN002 Selected)

43.3.3.2 Basic Operation (with Channel-Dedicated Sample-and-Hold Circuits)

When the channel-dedicated sample-and-hold circuit is used, sample-and-hold operation is first performed, and then A/D conversion is repeated on the analog input of all the selected channels as below. The channels whose channel-dedicated sample-and-hold circuit is to be used can be selected by the SHANS[3:0] bits in ADSHCR.

(1) Analog input sampling of all the channels whose channel-dedicated sample-and-hold circuit is to be used is started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input.
(2) After sample-and-hold operation, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled). At the same time, analog input sampling is started for all the channels whose channel-dedicated sample-and-hold circuit is to be used.
(5) The ADST bit is not automatically cleared and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(6) When the ADST bit is then set to 1 (A/D conversion start), analog input sampling is started again for all the channels whose channel-dedicated sample-and-hold circuit is to be used.



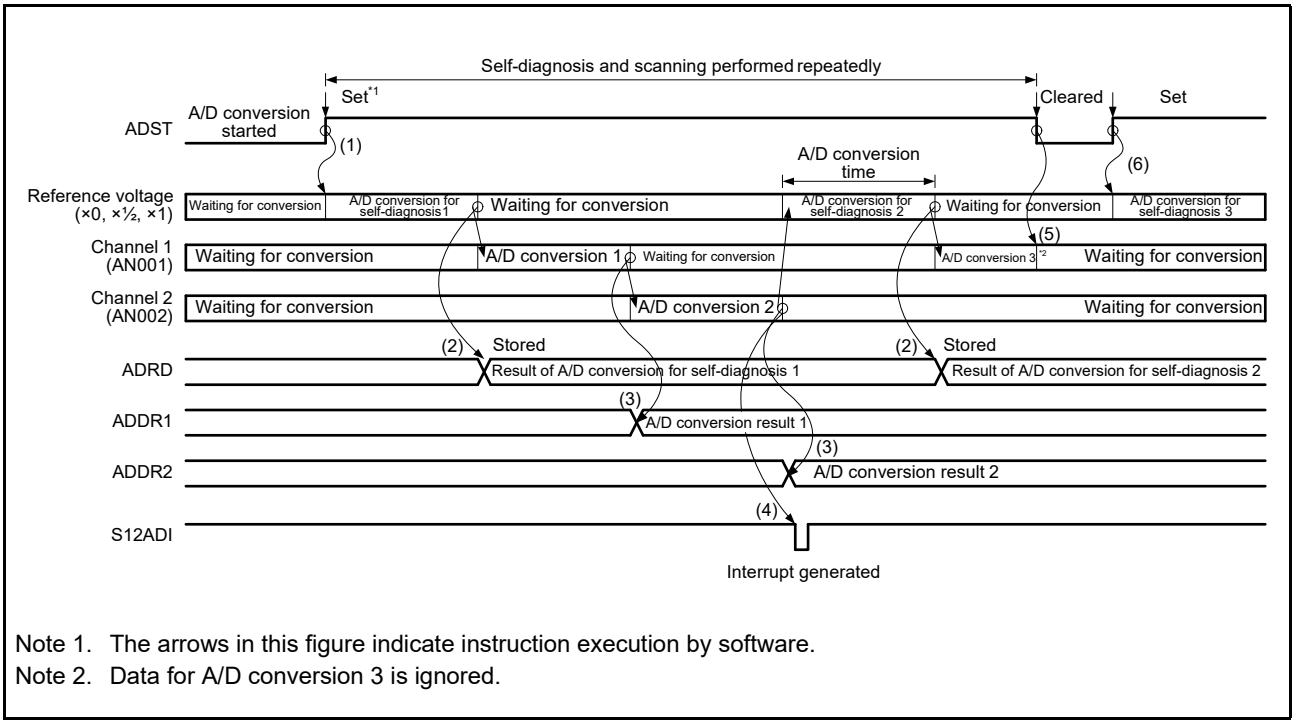
Note 1. The arrows in this figure indicate instruction execution by software.
Note 2. Data for A/D conversion 4 is ignored.

Figure 43.16 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000 and AN001 Selected)

43.3.3.3 Channel Selection and Self-Diagnosis (without Channel-Dedicated Sample-and-Hold Circuits)

When channels and self-diagnosis are selected at the same time, A/D conversion is first performed for the reference voltage VREFH0 (unit 0) or VREFH1 (unit 1) (reference voltage ×0, ×1/2, or ×1) supplied to the 12-bit A/D converter, and then A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below.

(1) A/D conversion due to self-diagnosis is first started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input.
(2) When A/D conversion due to self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled). At the same time, the 12-bit A/D converter starts A/D conversion due to self-diagnosis and then starts A/D conversion on ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(5) The ADST bit in ADCSR is not automatically cleared and steps 2 to 4 are repeated as long as the bit remains 1. When the ADST bit in ADCSR is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(6) When the ADST bit is later set to 1 (A/D conversion start), conversion is started again from the A/D conversion due to self-diagnosis.



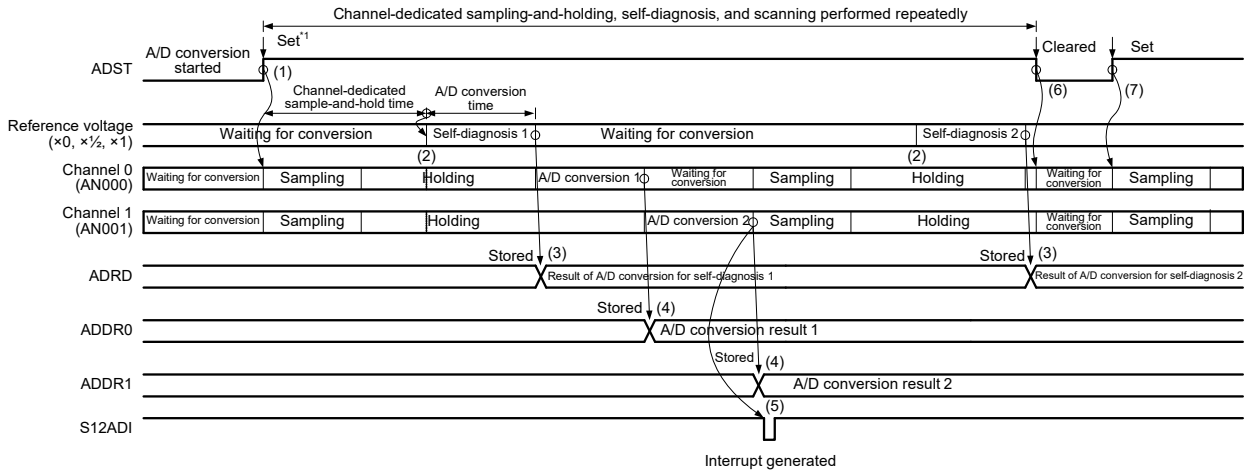
Note 1. The arrows in this figure indicate instruction execution by software.
Note 2. Data for A/D conversion 3 is ignored.

Figure 43.17 Example of Operation in Continuous Scan Mode (Basic Operation; AN001 and AN002 Selected + Self-Diagnosis)

43.3.3.4 Channel Selection and Self-Diagnosis (with Channel-Dedicated Sample-and-Hold Circuits)

When the channel-dedicated sample-and-hold circuit is used and channels and self-diagnosis are selected, sample-and-hold operation is first performed, and then A/D conversion is performed for the reference voltage VREFH0 (unit 0) or VREFH1 (unit 1) (reference voltage ×0, ×1/2, or ×1) supplied to the 12-bit A/D converter, and A/D conversion is performed on the analog input of the selected channels, which sequence is repeated as below. The ADSHCR.SHANS[3:0] bits are used to select the channels for which the channel-dedicated sample-and-hold circuit is used.

(1) Analog input sampling of all the channels whose channel-dedicated sample-and-hold circuit is to be used is started when the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input.
(2) After sample-and-hold operation, A/D conversion is started by self-diagnosis.
(3) When A/D conversion due to self-diagnosis is completed, the A/D conversion result is stored into the A/D self-diagnosis data register (ADRD). A/D conversion is then performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(4) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(5) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion enabled). At the same time, analog input sampling is started for all the channels whose channel-dedicated sample-and-hold circuit is to be used.
(6) The ADST bit is not automatically cleared and steps 2 to 5 are repeated as long as the bit remains 1. When the ADST bit is set to 0 (A/D conversion stop), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(7) When the ADST bit is then set to 1 (A/D conversion start), analog input sampling is started again for all the channels whose channel-dedicated sample-and-hold circuit is to be used.



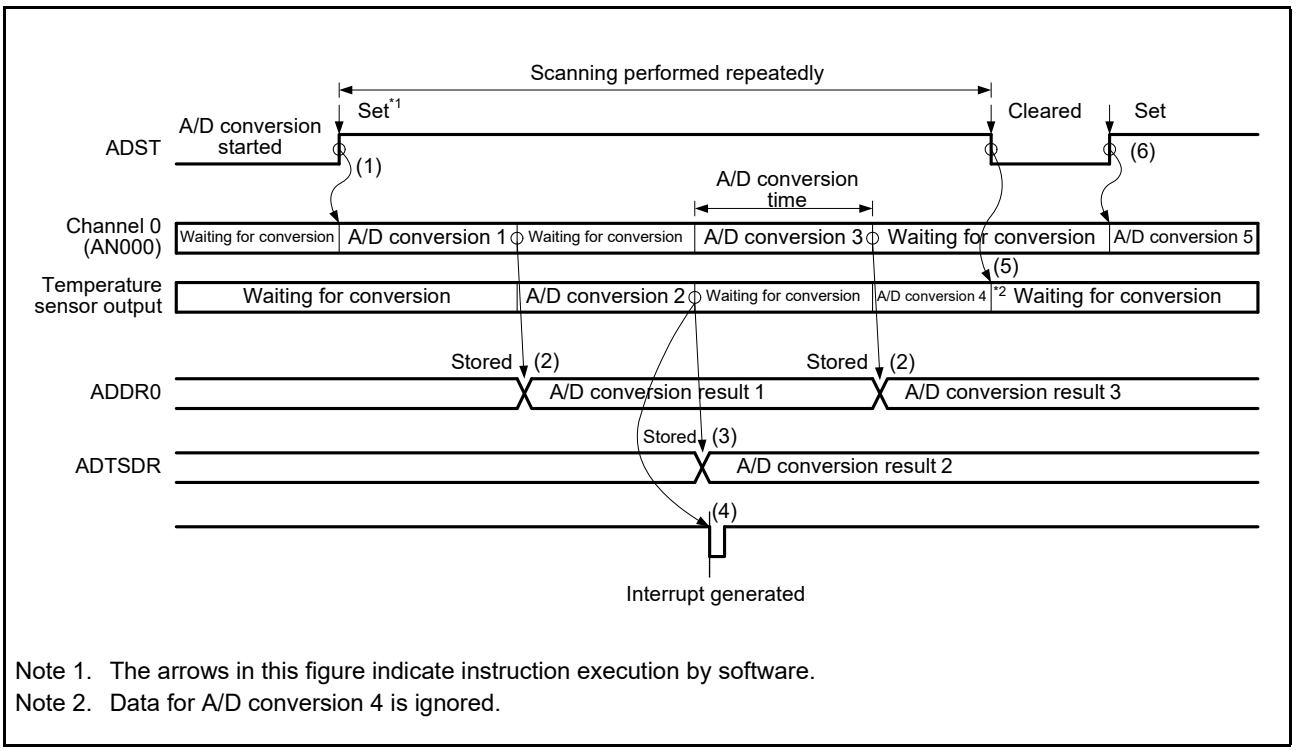
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.18 Example of Operation in Continuous Scan Mode (Channel-Dedicated Sample-and-Hold Circuits Used; AN000 and AN001 Selected + Self-Diagnosis)

43.3.3.5 A/D Conversion of Temperature Sensor Output

When the channels and temperature sensor output are selected at the same time, A/D conversion is first performed on the analog input of the selected channels, and then A/D conversion of the temperature sensor output is repeated as below. With the channels to be subjected to A/D conversion deselected, selecting only the temperature sensor output is also possible.

(1) When software, synchronous trigger (MTU3a, GPTa, TPUa, ELC), or asynchronous trigger sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn pins selected in the ADANSA register starts in order from the channel with the lowest number n.
(2) On completion of A/D conversion on the selected channel, the result is stored in the corresponding A/D data register (ADDRy), and then A/D conversion of temperature sensor output starts.
(3) On completion of A/D conversion of temperature sensor output, the result is stored in the corresponding A/D temperature sensor data register (ADTRDR).
(4) If the ADCSR.ADIE bit is set to 1 (enabling S12ADI interrupt generation upon scan conversion completion), an S12ADI interrupt is generated. Furthermore, the 12-bit A/D converter continuously starts A/D conversion for the ANn pins selected in the ADANSA register in order from the channel with the lowest number n.
(5) The ADCSR.ADST bit is not cleared automatically, and steps 2 to 4 are repeated as long as this bit remains set to 1. When the ADCSR.ADST bit is set to 0 (stopping A/D conversion), A/D conversion stops and the 12-bit A/D converter enters a waiting state.
(6) If the ADCSR.ADST bit is later set to 1 (starting A/D conversion), A/D conversion starts again for ANn pins selected by the ADANSA register in order from the channel with the lowest number n.



Note 1. The arrows in this figure indicate instruction execution by software.
Note 2. Data for A/D conversion 4 is ignored.

Figure 43.19 Example of Operation in Continuous Scan Mode (Basic Operation: AN000 and Temperature Sensor Output or Internal Reference Voltage Selected)

43.3.4 Group Scan Mode

43.3.4.1 Basic Operation

In basic operation of group scan mode, A/D conversion is performed once on the analog inputs of all the specified channels in group A and group B after scanning is started by a synchronous trigger (MTU3a, GPTa, TPUa, ELC) as below. Scan operation of each group is similar to the scan operation in single scan mode.
The synchronous triggers of group A and B can be selected using the TRSA[5:0] and TRSB[5:0] bits in ADSTRGR, respectively. The different triggers should be set for group A and group B to prevent simultaneous A/D conversion of group A and group B. Software trigger should not be used.
The ADANSA register and the TSSA bit in the ADEXICR register are used to select the channels subject to A/D conversion for group A. The ADANSB register and the TSSB bit in the ADEXICR register are used to select the channels subject to A/D conversion for group B. Group A and group B cannot use the same channels.
When self-diagnosis is selected in group scan mode, self-diagnosis is separately executed for group A and group B.
The following describes operation in group scan mode using a trigger of the MTU3a. Specifically, the TRG4AN and TRG4BN triggers of the MTU3a are assumed to be used to start conversion of group A and group B, respectively.

(1) Scanning of group A is started by the TRG4AN trigger of the MTU3a.
(2) When group A scanning is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion is enabled).
(3) Scanning of group B is started by the TRG4BN trigger of the MTU3a.
(4) When group B scanning is completed, an S12GBADI interrupt is generated if the GBADIE bit in ADCSR is 1 (S12GBADI interrupt upon scanning completion is enabled).

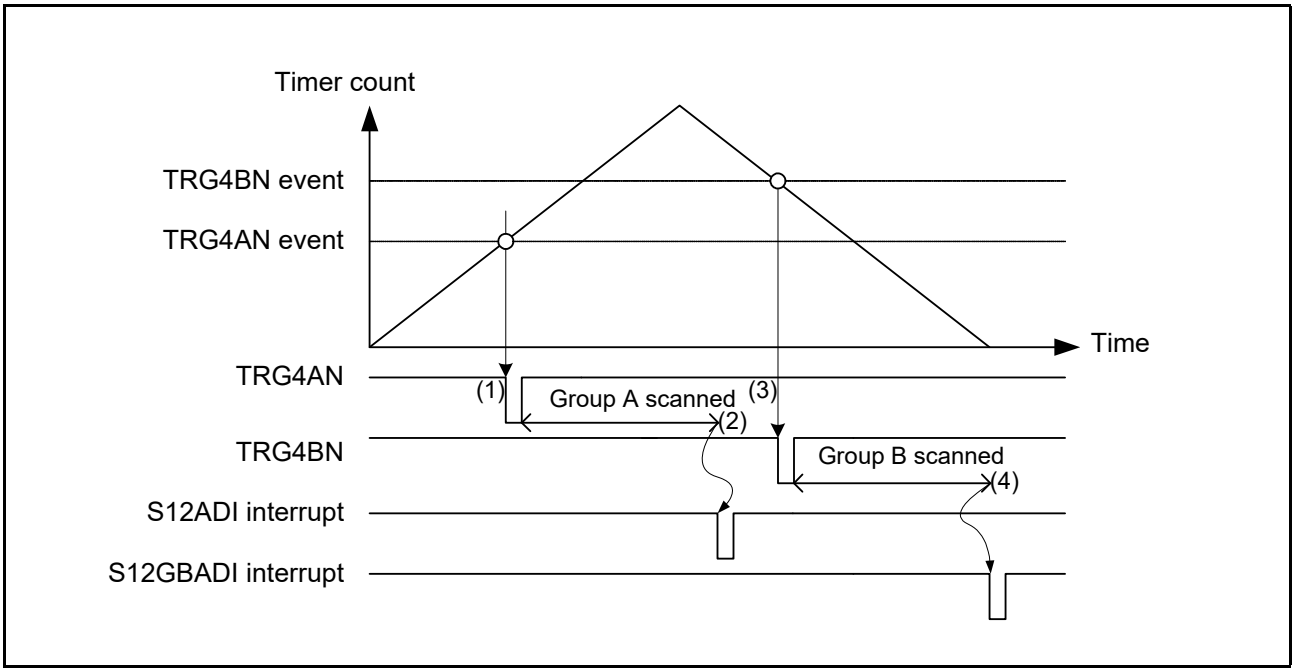


Figure 43.20 Example of Operation in Group Scan Mode (Basic Operation: Triggers from MTU3a Used)

43.3.4.2 A/D Conversion in Double Trigger Mode

When double trigger mode is selected in group scan mode, A/D conversion is performed for two rounds of single scan operation started by a synchronous trigger (MTU3a, GPTa, TPUa, ELC) as a sequence for group A. For group B, single scan operation started by a synchronous trigger (MTU3a, GPTa, TPUa, ELC) is performed once.

In group scan mode, the synchronous triggers of group A and B can be selected using the TRSA[5:0] and TRSB[5:0] bits in ADSTRGR, respectively. The different triggers should be selected for group A and group B to prevent simultaneous A/D conversion of group A and group B. Software trigger, or asynchronous trigger (ADTRGn) should not be used.

When a synchronous trigger TRGnAN or TRGnBN (n = 4, 7) is selected as the trigger for the start of A/D conversion (the ADSTRGR.TRSA[5:0] bits are set to 0Bh or 0Fh), or GTADTRAmN or GTADTRBmN (m = 0 to 3) is selected (the ADSTRGR.TRSA[5:0] bits are set to 19h, 1Ah, 1Bh, or 1Ch), operation proceeds in extended double trigger mode.

The DBLANS[4:0] bits in the ADCSR register are used to select the channels subject to A/D conversion for group A. The ADANSB register is used to select the channels subject to A/D conversion for group B. The same channels cannot be selected for both groups.

When double trigger mode is selected in group scan mode, the temperature sensor output A/D conversion select bits (ADEXICR.TSSA and ADEXICR.TSSB) should be set to 0 (deselected).

When double trigger mode is selected in group scan mode, self-diagnosis cannot be selected.

Duplication of A/D conversion data is enabled by setting the channel numbers to be duplicated to the DBLANS[4:0] bits in ADCSR and setting the DBLE bit in ADCSR to 1.

The following describes operation in group scan mode with double trigger mode using a trigger of the MTU3a. Specifically, the TRG4ABN and TRG0AN triggers of the MTU3a are assumed to be used to start conversion of group A and group B, respectively.

(1) Scanning of group B is started by the TRG0AN trigger of the MTU3a.
(2) When group B scanning is completed, an S12GBADI interrupt is generated if the GBADIE bit in ADCSR is 1 (S12GBADI interrupt upon scanning completion is enabled).
(3) The first scanning of group A is started by the first TRG4ABN trigger of the MTU3a.
(4) When the first scanning of group A is completed, the conversion result is stored into the corresponding A/D data register (ADDRy); an S12ADI interrupt is not generated irrespective of the ADIE bit setting in ADCSR.
(5) The second scanning of group A is started by the second TRG4ABN trigger of the MTU3a.
(6) When the second scanning of group A is completed, the conversion result is stored into the ADDBLDR register. An S12ADI interrupt is generated if the ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).

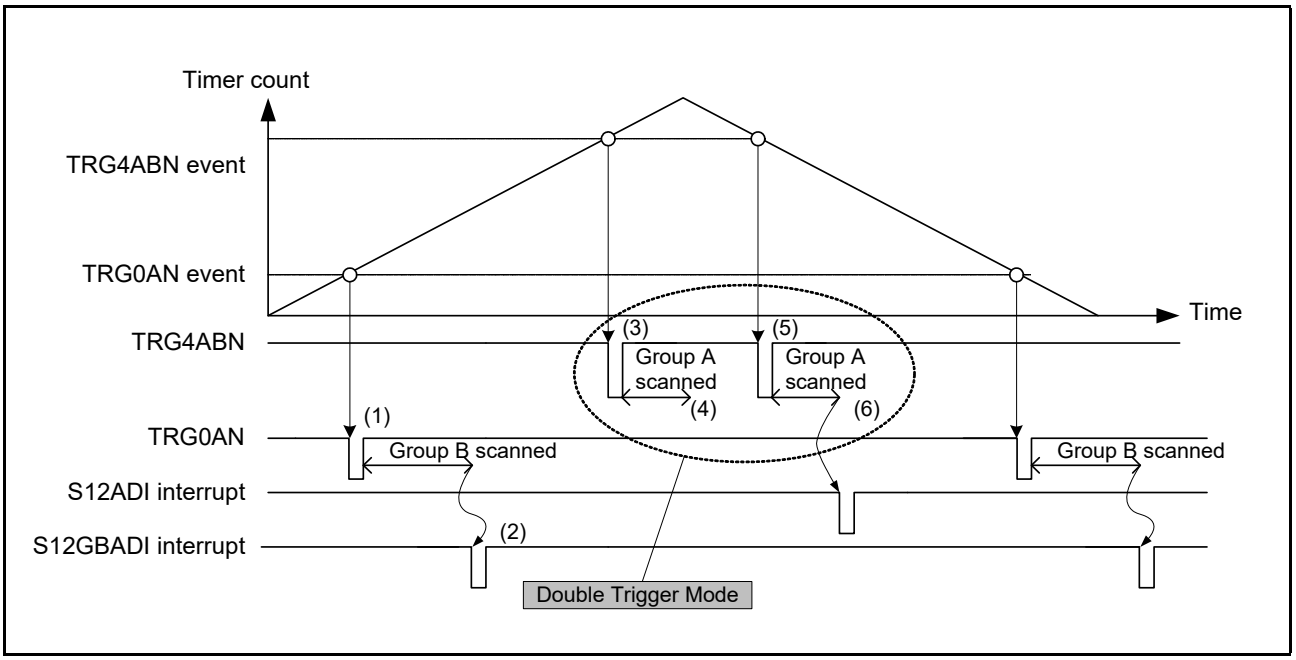

Figure 43.21 Example of Operation in Group Scan Mode with Double Trigger Mode (Basic Operation: Triggers from MTU3a Used)

43.3.4.3 Operation under Group-A Priority Control

Setting the ADGSPCR.PGS bit to 1 in group scan mode makes operation proceed under group-A priority control. When setting the PGS bit in the ADPGSCR register to 1, follow the procedure in Figure 43.22 to set the relevant registers. If the procedure is not followed, A/D conversion operation and stored data are not guaranteed.
In operation in basic group scan mode, input of the trigger for the other group during A/D conversion in group A or group B is ignored. Under group-A priority control, if a group-A trigger is input during A/D conversion for group B, A/D conversion for group B is discontinued and A/D conversion for group A proceeds. If the setting of the ADGSPCR.GBRSCN bit is 0, the converter enters the waiting state on completion of the A/D conversion for group A, without restarting the A/D conversion for group B (that was discontinued by the group-A trigger). If the setting of the ADGSPCR.GBRSCN bit is 1, the converter automatically restarts scanning for group B from the head of the group after completion of the A/D conversion for group A. Table 43.9 summarizes operations in response to the input of a trigger during A/D conversion with the settings of the ADGSPCR.GBRSCN bit.

Scan operations in group A or group B are the same in single scan mode. Furthermore, single scanning for group B continues to proceed if the ADGSPCR.GBRP bit is set to 1.

In group scan mode, select a synchronous trigger for group A using the ADSTRGR.TRSA[5:0] bits and select a synchronous trigger different from that of group A for group B using the ADSTRGR.TRSB[5:0] bits. Set the ADSTRGR.TRSB[5:0] bits to 3Fh when setting the ADGSPCR.GBRP bit to 1. Furthermore, as targets for A/D conversion, select channels for group A using the ADANSA register and the ADEXICR.TSSA bit, and for group B, select channels different from those for group A using the ADANSB register and the ADEXICR.TSSB bit.

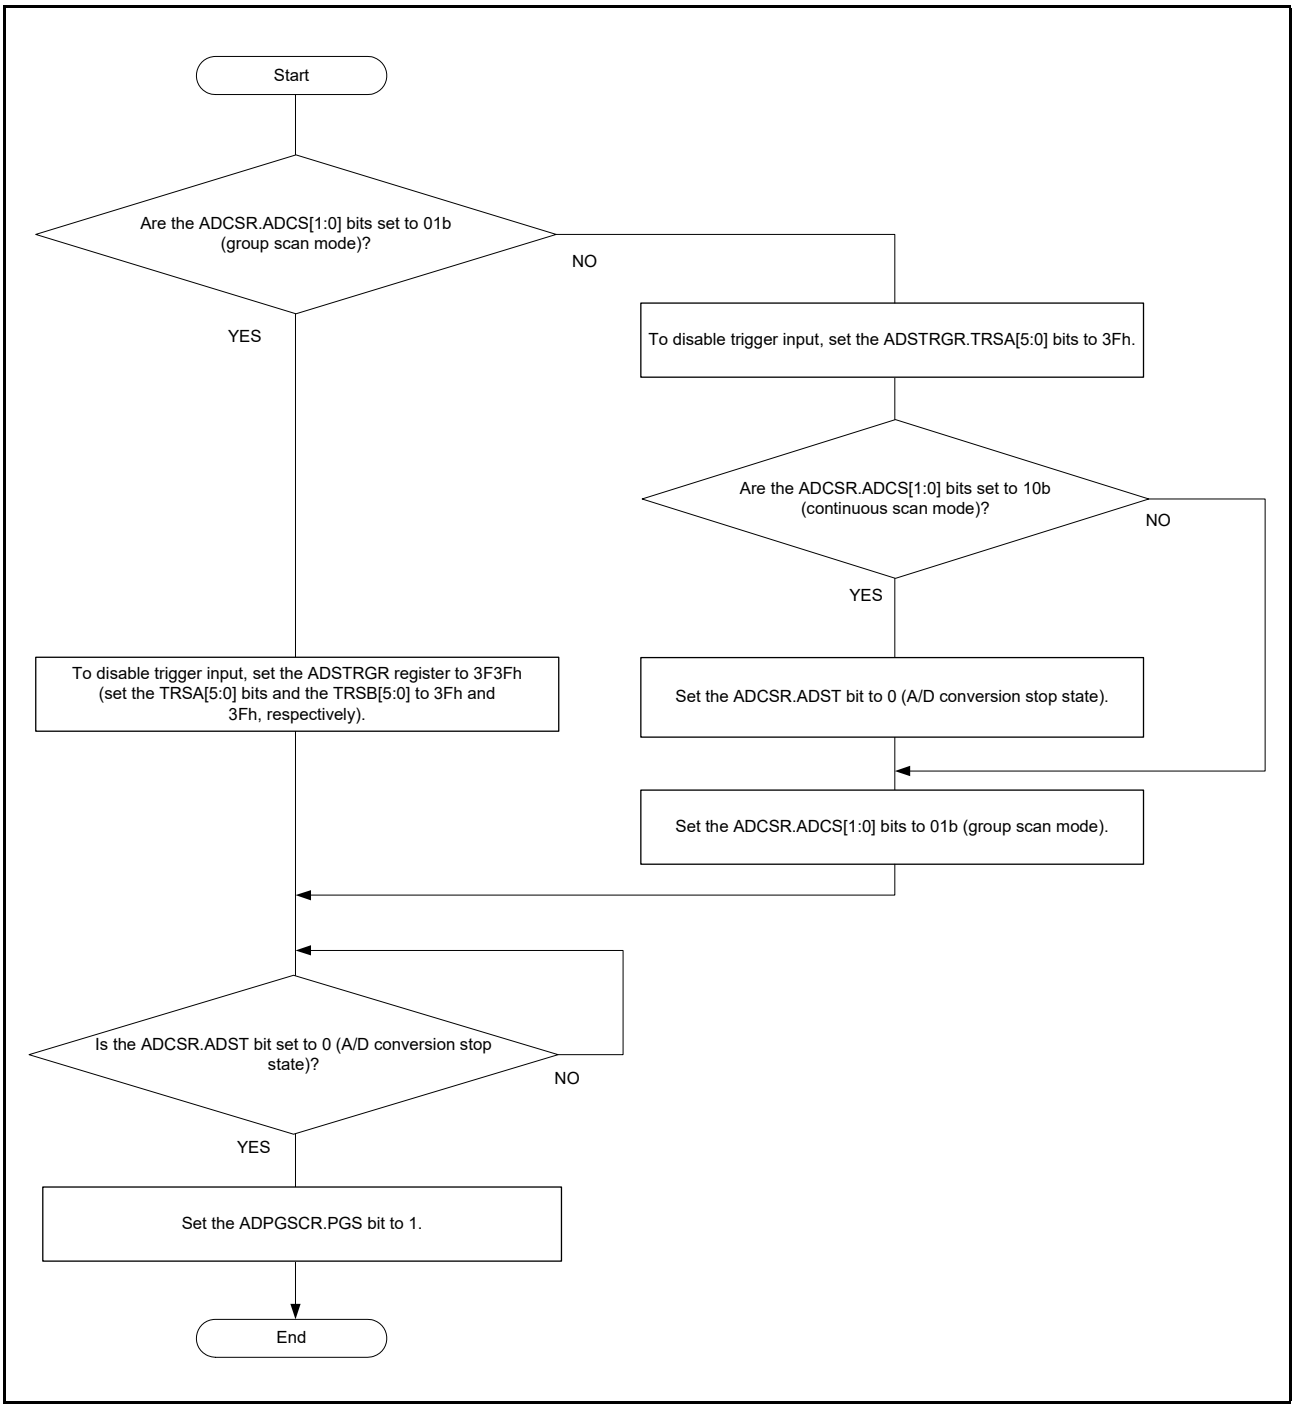

Figure 43.22 Flow of Setting the ADPGSCR.PGS Bit

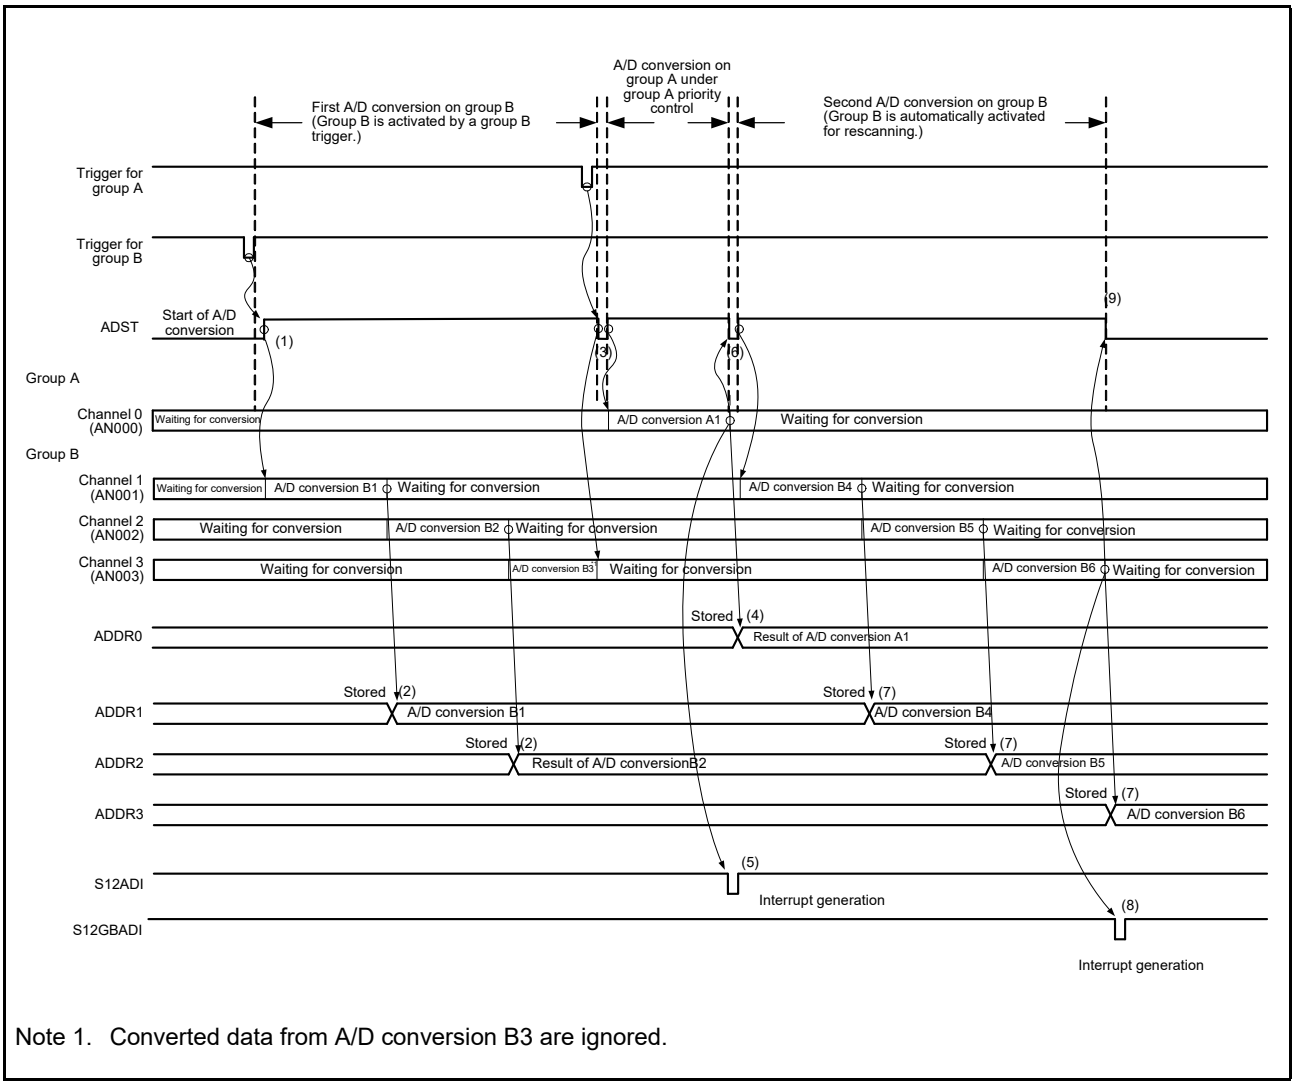
Table 43.9 Control of A/D Conversion Operations According to the Settings of the ADGSPCR.GBRSCN Bit

A/D Conversion Operation	Trigger Input	ADGSPCR.GBRSCN = 0	ADGSPCR.GBRSCN = 1
When A/D conversion for group A is in progress	Input of trigger for group A	Trigger input is ineffective.	Trigger input is ineffective.
	Input of trigger for group B	Trigger input is ineffective.	A/D conversion is performed on group B after A/D conversion on group A is completed.
When A/D conversion for group B is in progress	Input of trigger for group A	Conversion for group B that is in progress is discontinued and conversion for group A starts.	• Conversion in progress for group B is discontinued and conversion for group A starts. • Conversion for group B starts after conversion for group A is completed.
	Input of trigger for group B	Trigger input is ineffective.	Trigger input is ineffective.

The following describes the operations in group scan mode under group-A priority control (i.e. ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0) when channel 0 is selected for group A and channels 1 to 3 are selected for group B.

(1) When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channel pins selected in the ADANSB register starts in order from the channel with the lowest number.
(2) On completion of A/D conversion for a channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is cleared on the input of a trigger for group A while A/D conversion in group B is in progress, and the latter is discontinued. After that, the ADCSR.ADST bit is set to 1 (starting A/D conversion), and conversion for the ANn channel pins selected in the ADANSA register starts in order from the channel with the lowest number.
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(6) After the ADST bit is automatically cleared, again, the bit is automatically set to 1 (starting A/D conversion) and conversion for the ANn channel pins of group B selected in the ADANSB register starts in order from the channel with the lowest number.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(8) An S12GBADI interrupt is generated if the setting of the ADCSR.GBADIE bit is 1 (S12GBADI interrupt upon group B scanning completion enabled).
(9) The ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the A/D converter enters the waiting state.

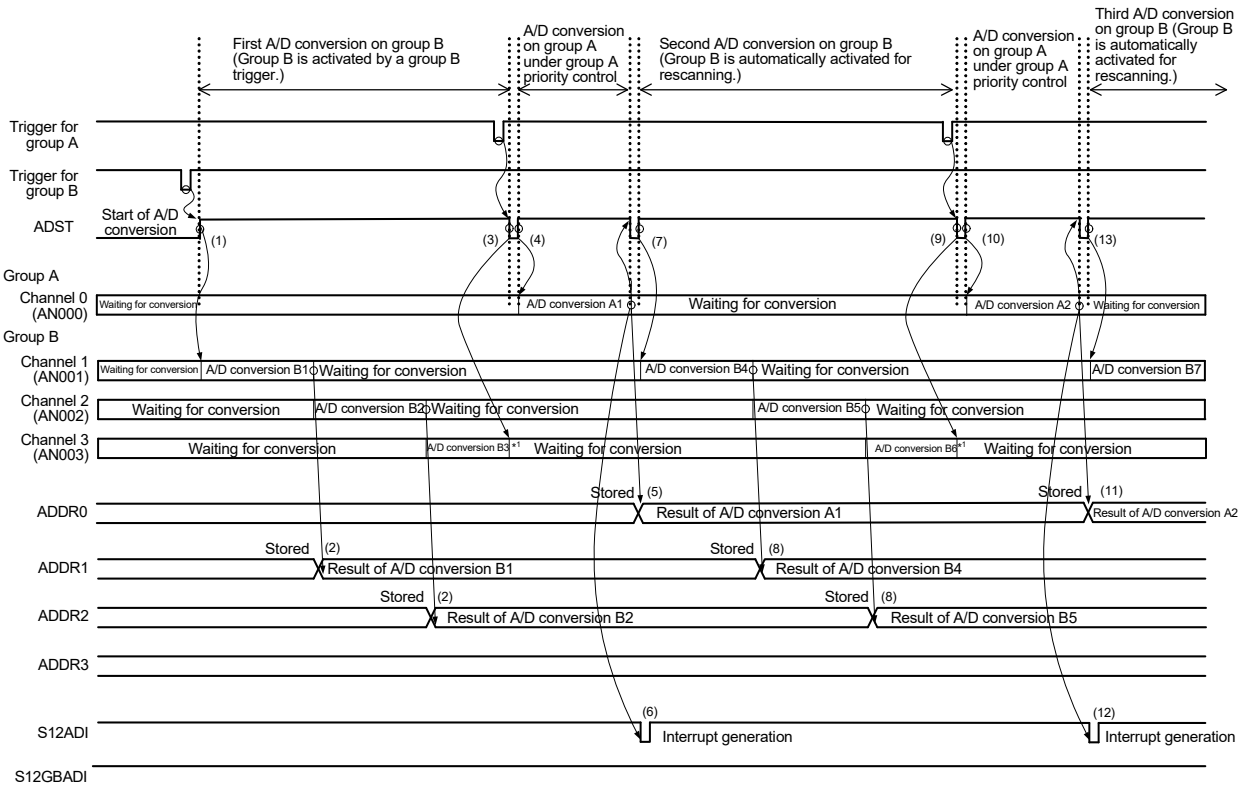


Note 1. Converted data from A/D conversion B3 are ignored.

Figure 43.23 Example of Operations under Group-A Priority Control (1) (when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0)

The following is an example when a group A trigger is input again during rescanning operation on group B. In this example, channel 0 is selected for group A and channels 1 to 3 are selected for group B when operation on group A is given priority (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0).

(1) When a group B trigger input sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channel pins of group B selected in the ADANSB register starts in order from the channel with the lowest number n.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) The ADCSR.ADST bit is cleared to 0 (stopping A/D conversion) on the input of a trigger for group A while A/D conversion in group B is in progress, and the latter is discontinued.
(4) After that, the ADCSR.ADST bit is set to 1 automatically and A/D conversion for the ANn group A channel pins selected in the ADANSA register starts in order from the channel with the lowest number n.
(5) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(6) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(7) On completion of A/D conversion on the group A, rescanning operation on group B sets the ADCSR.ADST bit to 1 automatically if the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning operation). After that, A/D conversion for the ANn group B channel pins selected in the ADANSB register starts again in order from the channel with the lowest number n.
(8) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(9) If a group A trigger is input during A/D conversion on group B for rescanning, the ADCSR.ADST bit is cleared to 0 (stopping A/D conversion) and the ongoing A/D conversion on group B is stopped.
(10) After that, the ADCSR.ADST bit is set to 1 automatically and A/D conversion for the ANn group A channel pins selected in the ADANSA register starts in order from the channel with the lowest number n.
(11) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(12) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(13) On completion of A/D conversion on group A, rescanning operation on group B sets the ADCSR.ADST bit to 1 automatically if the setting of the ADGSPCR.GBRSCN bit is 1 (enabling rescanning operation). After that, A/D conversion for the ANn group B channel pins selected in the ADANSB register starts again in order from the channel with the lowest number n.
(14) If a group A trigger is input during A/D conversion on group B for rescanning, steps 9 to 13 are repeated. If a group A trigger is not input, the ADCSR.ADST bit is cleared automatically on completion of A/D conversion on group B and the 12-bit A/D converter enters a waiting state.



Note 1. Conversion data from A/D conversion B3 and B6 are ignored.

Figure 43.24 Example of Operations under Group-A Priority Control (2) (when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0)

The following is an example of a rescanning operation in which a group B trigger is input during A/D conversion on group A. In this example, channels 1 to 3 are selected for group A and channel 0 is selected for group B when operation on group A is given priority (ADGSPCR.GBRSCN = 1, ADGSPCR.GBRP = 0).

(1) When input of a trigger for group A sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channel pins of group A selected in the ADANSA register starts in order from the channel with the lowest number.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group B trigger is input during A/D conversion on group A, A/D conversion on group B can be performed after the A/D conversion on group A is completed. (However, if group A triggers are input continuously, the scan operation on group B is cancelled by conversion on group A and is not performed.)
(4) On completion of the A/D conversion on the group A, an S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(5) On completion of the A/D conversion on the group A, activation of group B for rescanning sets the ADCSR.ADST bit to 1 automatically.
After that, conversion for the ANn channel pins of group B selected in the ADANSB register starts again in order from the channel with the lowest number.
(6) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(7) On completion of the rescanning operation on the group B, an S12GBADI interrupt is generated if the setting of the ADCSR.GBADIE bit is 1 (S12GBADI interrupt upon scanning completion is enabled).
(8) The ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is automatically cleared on completion of conversion, after which the A/D converter enters a waiting state.

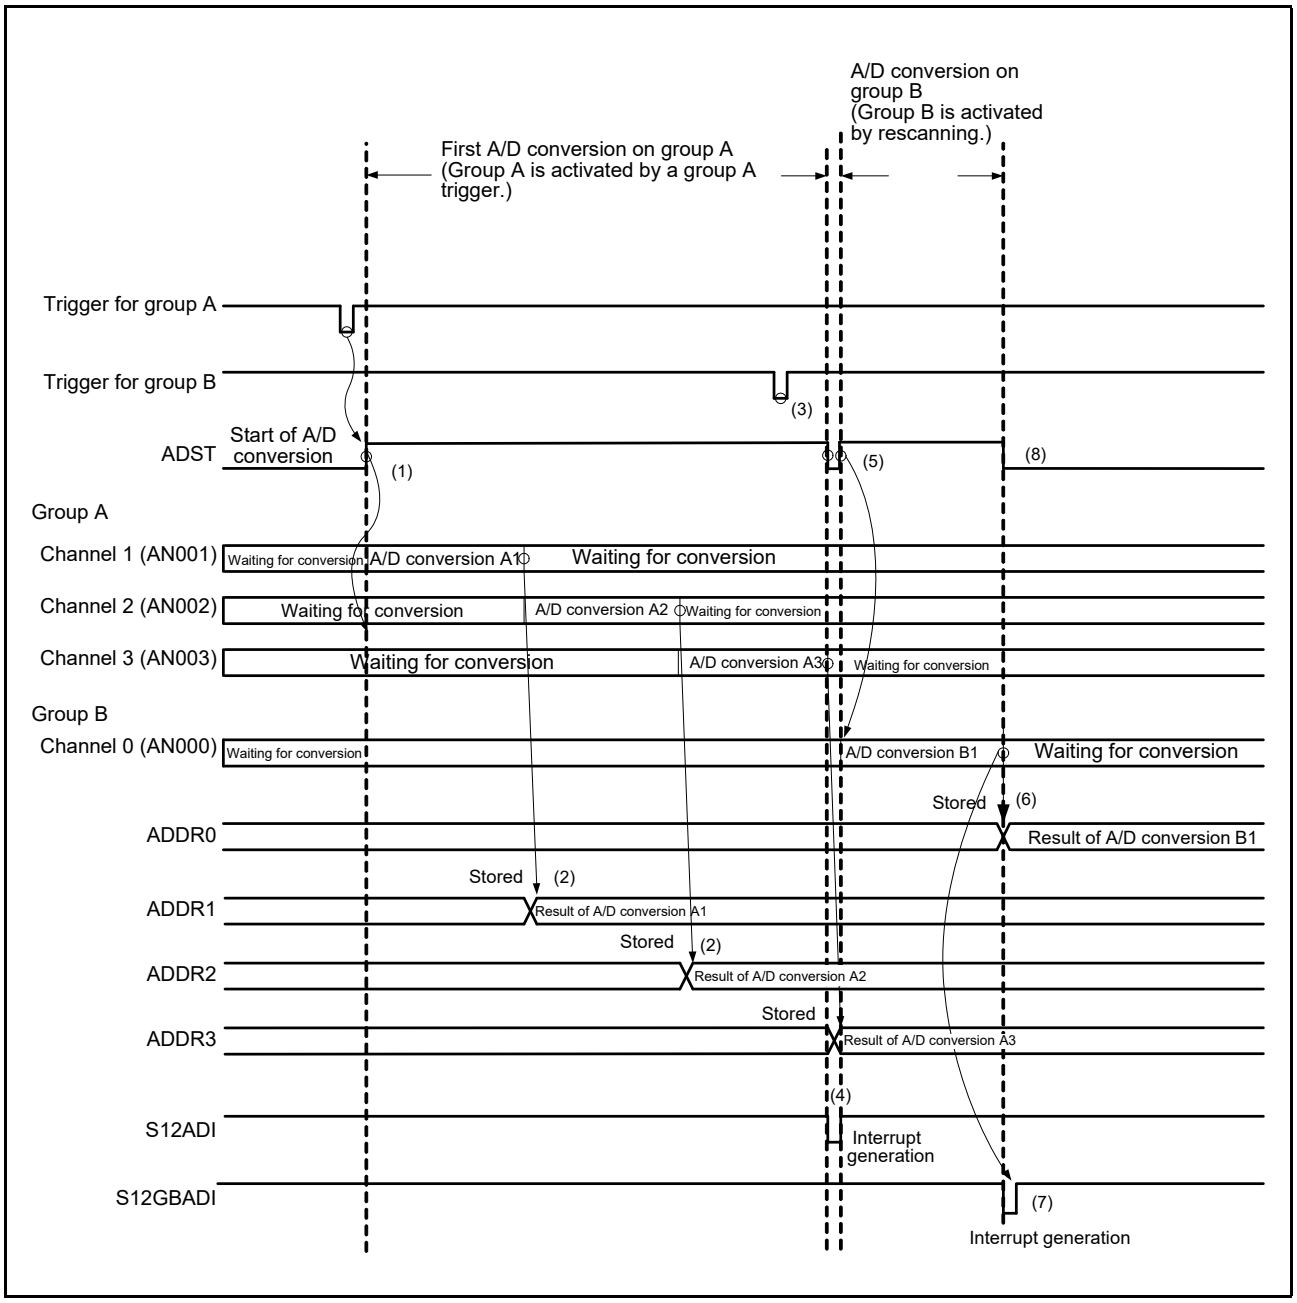


Figure 43.25 Example of Operations under Group-A Priority Control (3) (when ADGSPCR.GBRSCN = 1 and ADGSPCR.GBRP = 0)

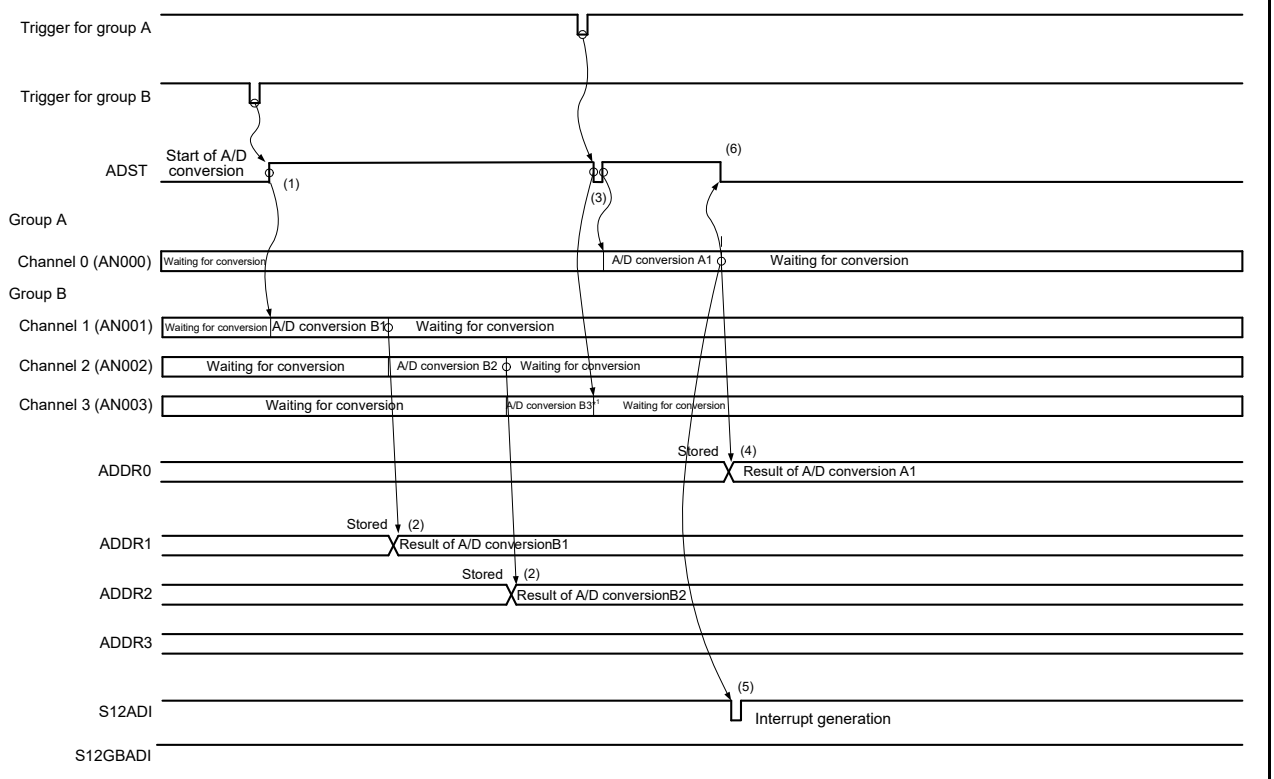
The following is an example of operation under group-A priority control in which channel 0 is selected for group A and channels 1 to 3 are selected for group B (ADGSCR.GBRSCN = 0, ADGSCR.GBRP = 0).

(1) When input of a trigger for group B sets the ADCSR.ADST bit to 1 (starting A/D conversion), conversion for the ANn channel pins selected in the ADANSB register starts in order from the channel with the lowest number.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group A trigger is input during A/D conversion on group B, the ADCSR.ADST bit is cleared to 0 and the ongoing A/D conversion on group B is stopped. After that, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and conversion for the ANn channel pins selected in the ADANSA register starts in order from the channel with the lowest number.
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(6) The ADCSR.ADST bit retains the value 1 (starting A/D conversion) during A/D conversion and is cleared on completion of conversion, after which the A/D converter enters the waiting state.

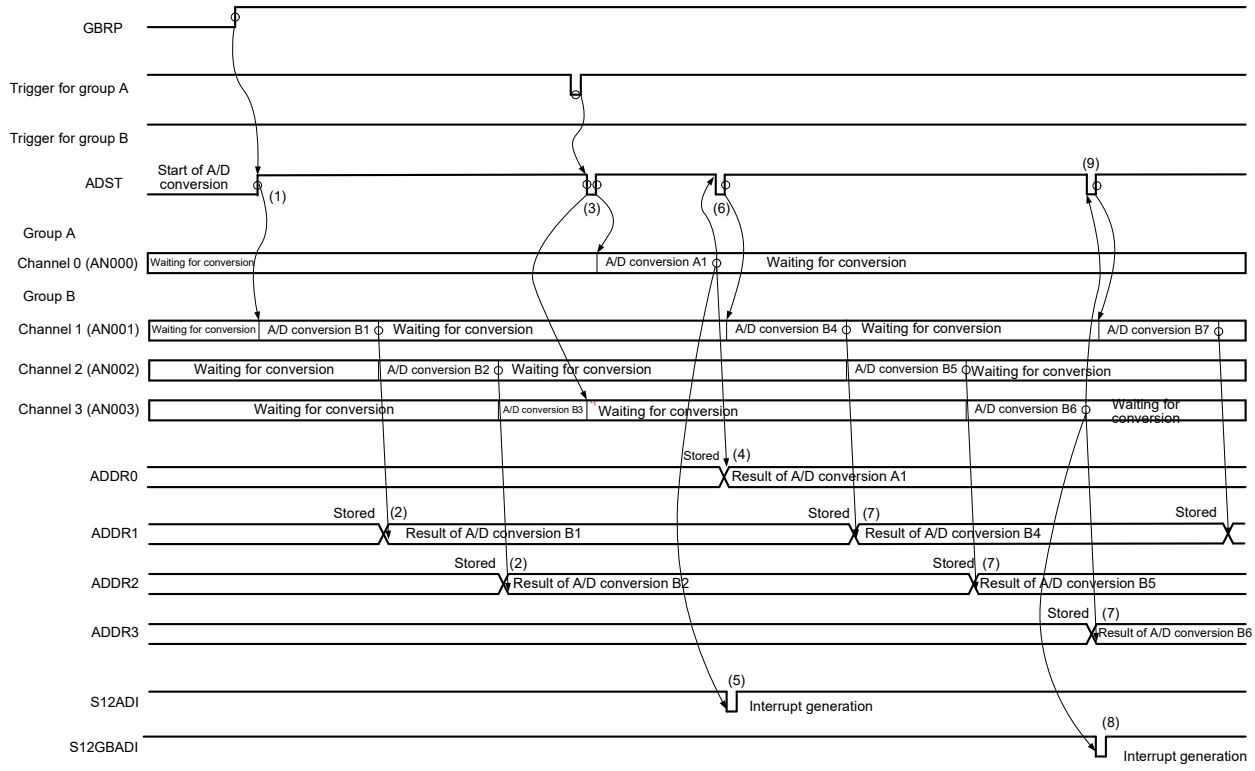


Note 1. The converted data of A/D conversion B3 is ignored.

Figure 43.26 Example of Operation under Group-A Priority Control (4) (when ADGSPCR.GBRSCN = 0 and ADGSPCR.GBRP = 0)

The following is an example of operation under group A priority control in which channel 0 is selected for group A and channels 1 to 3 are selected for group B (ADGSCR.GBRP = 1).

(1) The ADCSR.ADST bit is set to 1 (starting A/D conversion) when ADGSPCR.GBRP is set to 1, and conversion for the ANn channel pins selected in the ADANSB register starts in order from the channel with the lowest number.
(2) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(3) If a group A trigger is input during A/D conversion on group B, the ADCSR.ADST bit is cleared to 0 and the ongoing A/D conversion on group B is stopped. After that, the ADCSR.ADST bit is set to 1 (starting A/D conversion) and conversion for the ANn channel pins selected in the ADANSA register starts in order from the channel with the lowest number.
(4) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(5) An S12ADI interrupt is generated if the setting of the ADCSR.ADIE bit is 1 (S12ADI interrupt upon scanning completion is enabled).
(6) After the ADST bit is automatically cleared and then is automatically set to 1 (starting A/D conversion) again, conversion for the ANn channel pins selected in the ADANSB register starts again in order from the channel with the lowest number.
(7) On completion of A/D conversion on a single channel, the result is stored in the corresponding A/D data register (ADDRy).
(8) An S12GBADI interrupt is generated if the setting of the ADCSR. GBADIE bit is 1 (S12GBADI interrupt upon completion of scanning for group B is enabled).
(9) After the ADST bit is automatically cleared, again, the bit is automatically set to 1 (starting A/D conversion), and then conversion for the ANn channel pins selected in the ADANSB register starts again in order from the channel with the lowest number. Steps 6 to 9 are repeated as long as the ADGSPCR.GBRP bit remains 1.
Clearing of the ADCSR.ADST bit to 0 is prohibited while the ADGSPCR.GBRP bit is set to 1.
Follow the procedure for clear operation by software through the ADCSR.ADST bit, shown in Figure 43.40, if you wish to forcibly stop A/D conversion while ADGSPCR.GBRP = 1.



Note 1. Converted data from A/D conversion B3 are ignored.

Figure 43.27 Example of Operation under Group-A Priority Control (5) (when ADGSPCR.GBRP = 1)

43.3.5 Extended Analog Input (Unit 1)

The extended analog input AN1_ANEX1 is used when an external operational amplifier is connected to this LSI to perform
A/D conversion for the multiple analog values. When the extended analog input is selected, AN100 to AN107 can only be selected. Do not select AN108 to AN115, and self-diagnosis function. Also, the disconnection detection assist function cannot be used. Furthermore, when the extended analog input is selected, if the pin-level self-diagnosis function is enabled, the diagnosis is performed for the extended analog input (AN1_ANEX1) and not for AN100 to AN107 and AN1_ANEX0 even if AN100 to AN107 are selected as the targets.

43.3.5.1 Usage of AN1_ANEX1

To perform A/D conversion of the multiple analog values via the operational amplifier, input the analog signal to the analog input channels (AN100 to AN107). Then take out the time-divided analog values from the extended analog output pin (AN1_ANEX0), and connect the operational amplifier between the AN1_ANEX0 pin and AN1_ANEX1 pin.
To select AN1_ANEX1, set the ADEXICR.EXSEL[1:0] bits to 01b. To enable AN1_ANEX0 output, set the ADEXICR.EXOEN bit to 1. Also select single scan mode or continuous scan mode. Do not select group scan mode.
Figure 43.28 shows an example of the extended analog input circuit configuration with AN1_ANEX1 used. Figure 43.29 shows the operation when three channels (AN100, AN101, and AN102) and single scan mode are selected.

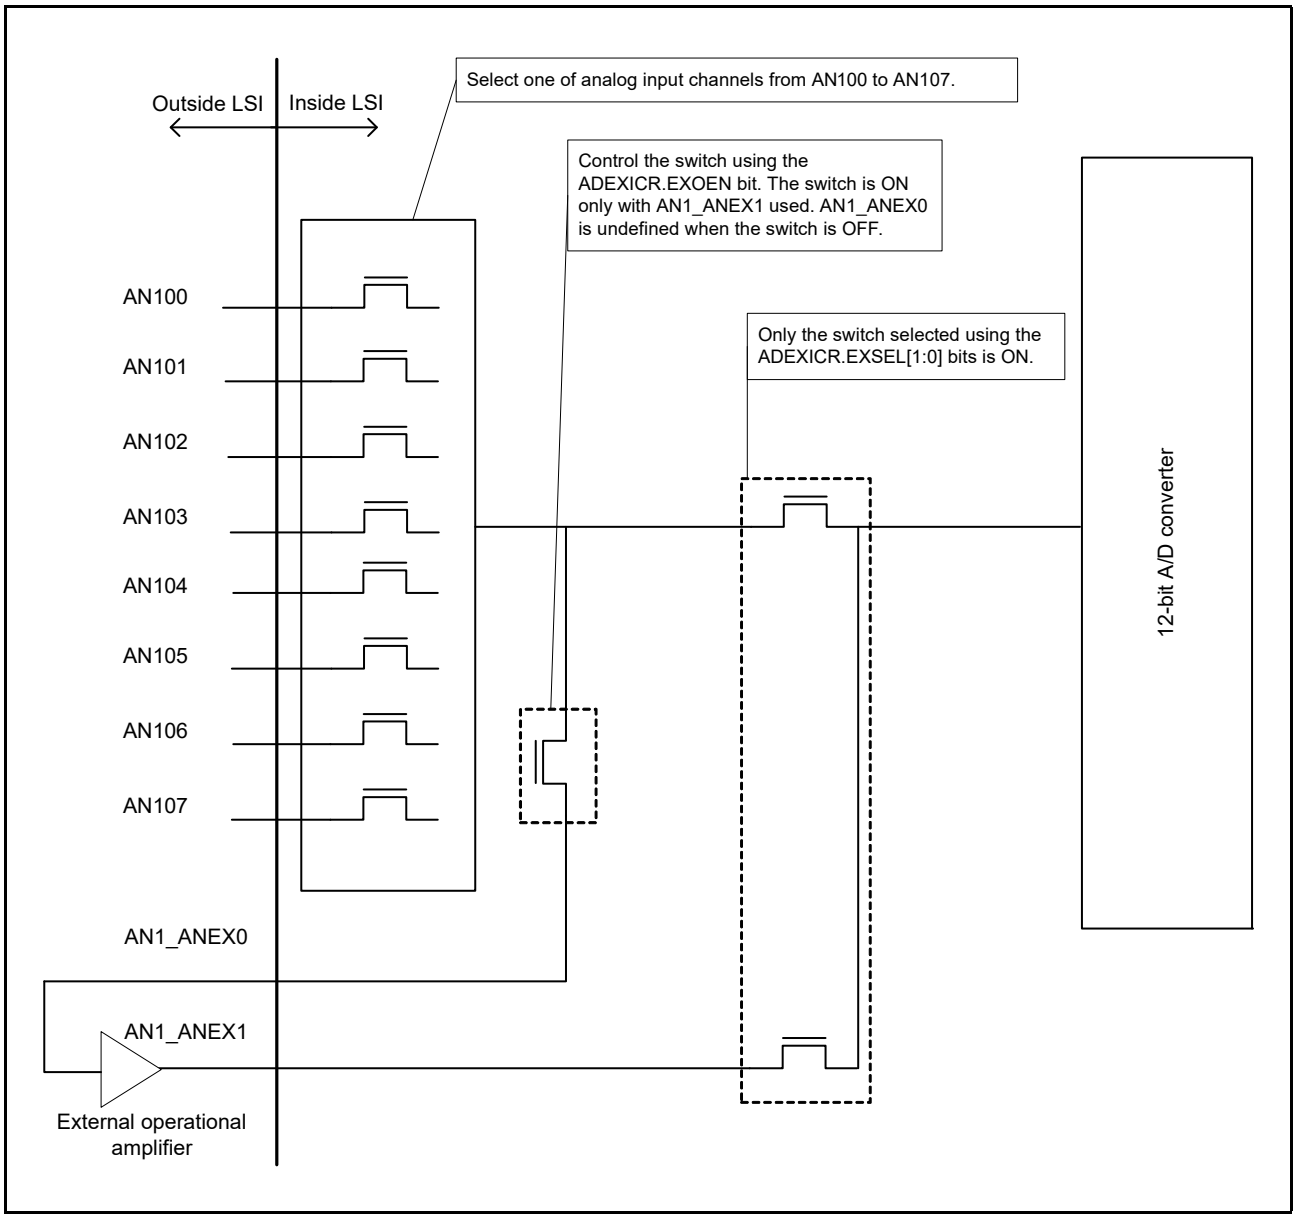


Figure 43.28 Configuration Example of Extended Analog Input Circuit with AN1_ANEX1 Used

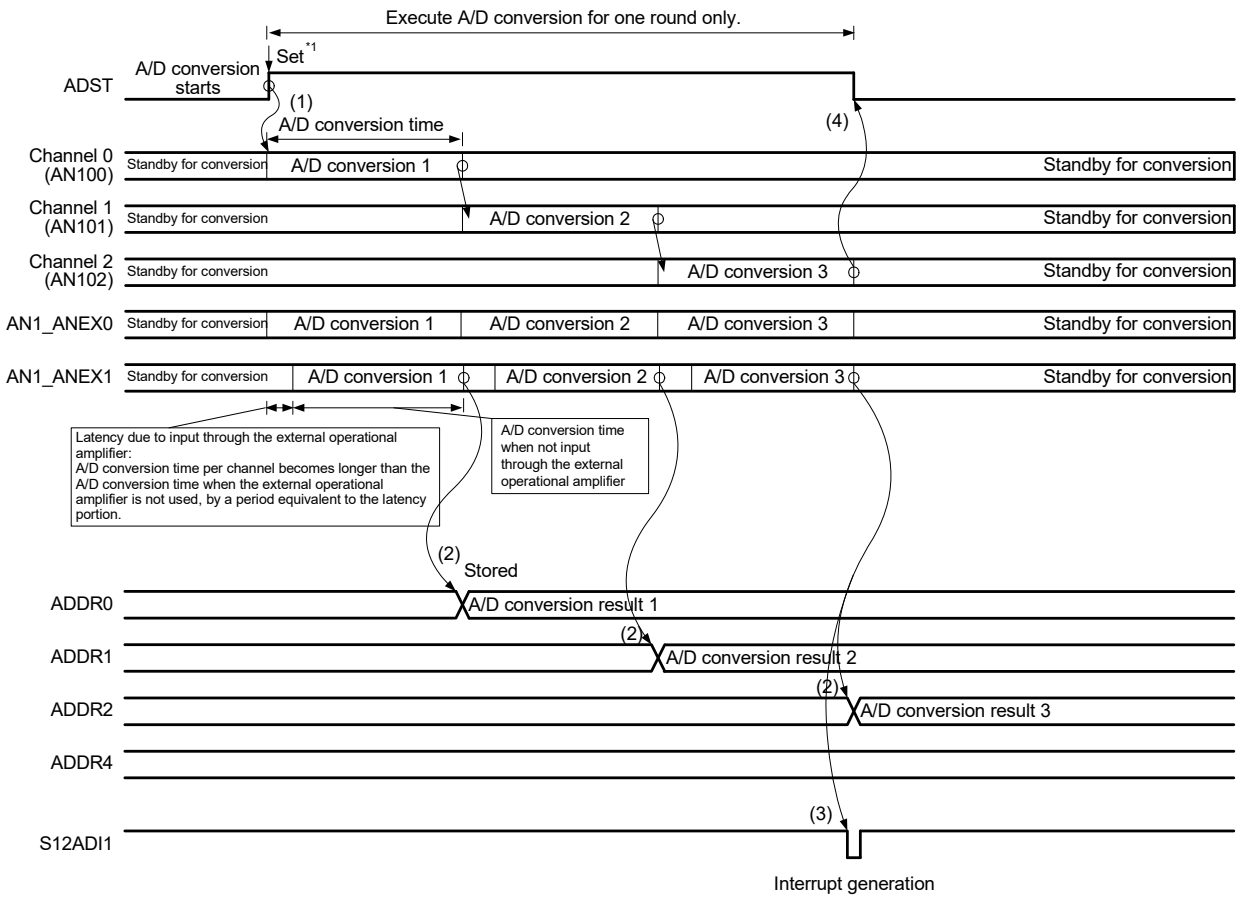
(1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input, A/D conversion is performed for the selected channels, starting from the channel with the smallest number.

(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon scanning completion is enabled).

(4) The ADST bit remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.29 AN1_ANEX1 Input Operation Example (Single Scan Mode)

When the extended analog input is selected, each A/D conversion time becomes longer due to the latency of the operational amplifier, compared to the A/D conversion that is directly performed for the analog input channels.

43.3.6 Comparison

Comparison is of a reference value set in a register with the result of A/D conversion on selected channels. Self-diagnosis function and double-triggered mode are not available while comparison is in use.

Operation using comparison in combination with continuous scan mode is described below.

(1) A/D conversion is started in the order of the selected channels and the temperature sensor output when ADCSR.ADST is set to 1 (to start A/D conversion) by software, or in response to a synchronous trigger (MTU3a, GPTa, TPUa, ELC) or asynchronous trigger.

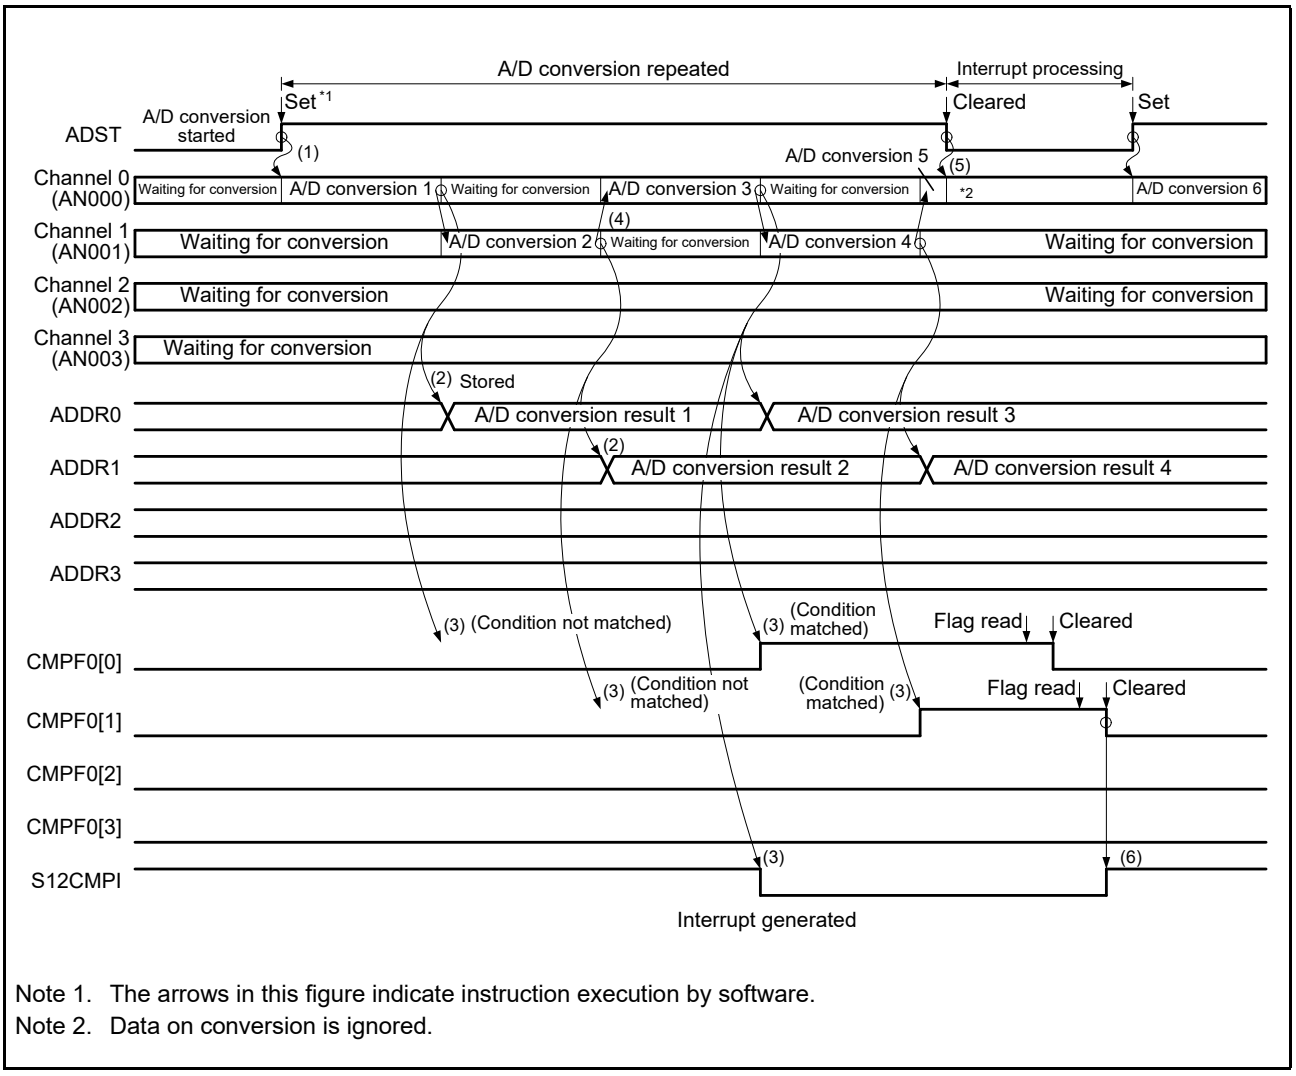
(2) When A/D conversion is completed, the result is stored in the A/D self-diagnosis data register (ADDRy, ADTSDR). If the register is selected for comparison by the settings of the ADCMPANSR and ADCMPANSER registers, its value is then compared with that of the ADCMPDR0/1 registers.

(3) If the result of comparison meets the condition set in the ADCMPCR.WCMPE bit, the ADCMPLR register, and the ADCMPLER register, the bits ADCMPSR.CMPFn and ADCMPSER.CMPFTS are set to 1. If the setting of the ADCMPCR.CMPIE bit is 1 at this time, an S12CMPI interrupt is also generated.

(4) When A/D conversion is completed for all selected channels, A/D conversion is started again.

(5) If the setting of the ADCSR.ADST bit is 0 (A/D conversion stop) after the S12CMPI interrupt is accepted, the interrupt processing proceeds for channels that have the compare flag.

(6) The S12CMPI interrupt signal is deasserted when all of the compare flags have been cleared. To start further comparison, start A/D conversion again.



Note 1. The arrows in this figure indicate instruction execution by software.
Note 2. Data on conversion is ignored.

Figure 43.30 Example of Operation Using Compare Function (AN000, AN001, AN002, and AN003 Selected for Comparison)

43.3.7 Analog Input Sampling and Scan Conversion Time

Scan conversion can be activated either by a software trigger; a synchronous trigger (MTU3a, GPTa, TPUa, ELC); or an asynchronous trigger (ADTRGn). After the start-of-scanning-delay time (t_D) has elapsed, processing by the channel-dedicated sample-and-hold circuits, processing for disconnection detection assistance, and processing of conversion for self-diagnosis proceed, and this is followed by A/D conversion.

Figure 43.31 shows the scan conversion timing in single scan mode, in which scan conversion is activated by a software trigger or a synchronous trigger (MTU3a, GPTa, TPUa, ELC). Figure 43.32 shows the scan conversion timing in single scan mode, in which scan conversion is activated by an asynchronous trigger ADTRGn. The scan conversion time (t_{SCAN}) includes the start-of-scanning-delay time (t_D), channel-dedicated sample-and-hold circuit processing time (t_{SPLSH})*1, disconnection detection assistance processing time (t_{DIS})*2, self-diagnosis A/D conversion processing time (t_{DIAG})*3, A/D conversion processing time (t_{CONV}), channel-dedicated sample-and-hold circuit end time (t_{SHED})*4, and end-of-scanning-delay time (t_{ED}).

The A/D conversion processing time (t_{CONV}) consists of input sampling time (t_{SPL}) and time for conversion by successive approximation (t_{SAM}). The sampling time (t_{SPL}) is used to charge sample-and-hold circuits in the A/D converter. If there is not sufficient sampling time due to the high impedance of an analog input signal source, or if the A/D conversion clock (ADCLK) is slow, sampling time can be adjusted using the ADSSTR register.

The time for conversion by successive approximation (t_{SAM}) is at 13 ADCLK states with 12-bit accuracy selected, 11 ADCLK states with 10-bit accuracy selected, and 9 ADCLK states with 8-bit accuracy selected. Table 43.11 shows the scan conversion time.

The scan conversion time (t_{SCAN}) in single scan mode for which the number of selected channels is n can be determined as follows:

$$t_{SCAN} = t_D + t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n) + t_{ED}$$

The scan conversion time for the first cycle in continuous scan mode is t_{SCAN} for single scan minus t_{ED} plus t_{SHED}. The scan conversion time for the second and subsequent cycles in continuous scan mode is fixed to $t_{SPLSH} + (t_{DIS} \times n) + t_{DIAG} + (t_{CONV} \times n) + t_{SHED}$.

Note 1. When no channel-dedicated sample-and-hold circuits are used, $t_{SH} = 0$.
Note 2. When disconnection detection assistance is not selected, $t_{DIS} = 0$.
Note 3. When the self-diagnosis function is not used, $t_{DIAG} = 0$.
Note 4. When no channel-dedicated sample-and-hold circuits are used, $t_{SHED} = 0$. Here, continuous scan mode is assumed. In single scan mode and group scan mode, t_{SHED} is included in the end-of-scanning-delay time (t_{ED}).

Table 43.10 Example of Setting the ADSSTR Register

Use	Setting Range	Sampling Time*1
Standard (initial value)	0Bh	0.18 µs (For ADCLK = 60 MHz)
Use this range if there is not sufficient sampling time due to the high impedance of an analog input signal source.	0Ch to FFh	Example: FFh 4.3 µs (For ADCLK = 60 MHz)
Use this range if ADCLK is less than 60 MHz and the sampling time needs to be less than the initial value.	05h to 0Ah	Example: 0Ah 0.67 µs (For ADCLK = 15 MHz)

Note 1. The sampling time is determined by the following formula.

$$\text{Sampling time (µs)} = \frac{\text{ADSSTR register setting}}{\text{ADCLK (MHz)}}$$

Table 43.11 Times for Conversion during Scanning (in Numbers of Cycles of the ADCLK and PCLKH)

Item			Symbol		Type/Conditions: Synchronous Trigger MTUa, GPTa	Synchronous Trigger TPUa, ELC	Asynchronous Trigger	Software Trigger	Unit
Scan start processing time*1, *2	A/D conversion on group A under group A priority control.	Group B is to be stopped. (Group A is activated after group B is stopped due to an A/D conversion source of group A.)	t_D		4 PCLKH + 6 ADCLK	3 PCLKH + 6 ADCLK	—	—	Cycle
		Group B is not to be stopped. (Activation by an A/D conversion source of group A.)			3 PCLKH + 4 ADCLK	2 PCLKH + 4 ADCLK	—	—	
	A/D conversion when self-diagnosis is enabled	A/D conversion for self-diagnosis is to be started.			3 PCLKH + 6 ADCLK	2 PCLKH + 6 ADCLK	4 PCLKH + 6 ADCLK	6 ADCLK	
		Normal A/D conversion is to be started after completion of self-diagnosis conversion.			2 ADCLK	2 ADCLK	2 ADCLK	2 ADCLK	
		A/D conversion for self-diagnosis is to be started after completion of conversion for continuous scan on the last channel specified.			2 ADCLK	2 ADCLK	2 ADCLK	2 ADCLK	
	Other than above				3 PCLKH + 4 ADCLK	2 PCLKH + 4 ADCLK	4 PCLKH + 4 ADCLK	4 ADCLK	
Channel-dedicated sample-and-hold processing time*1	Sampling time		t_{SPLSH}	t_{SH}	The setting of ADSHCR.SSTSH[7:0] (initial value = 18h) × ADCLK				
	Wait time between sampling and A/D Conversion			t_W	12 ADCLK				
Disconnection detection assistance processing time			t_{DIS}		The setting of ADNDIS[3:0] (initial value = 00h) × ADCLK				
Self-diagnosis conversion processing time*1	Sampling time		t_{DIAG}	t_{SPL}	The setting of ADSSTR0 (initial value = 0Bh) × ADCLK				
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	15 ADCLK				
		10-bit conversion accuracy			13 ADCLK				
		8-bit conversion accuracy			11 ADCLK				
A/D conversion processing time*1	Sampling time		t_{CONV}	t_{SPL}	The setting of ADSSTRn (n = 0 to 7, L, T) (initial value = 0Bh) × ADCLK				
	Time for conversion by successive approximation	12-bit conversion accuracy		t_{SAM}	13 ADCLK				
		10-bit conversion accuracy			11 ADCLK				
		8-bit conversion accuracy			9 ADCLK				
Channel-dedicated sample-and-hold end processing time			t_{SHED}		2 ADCLK				
Scan end processing time*1			t_{ED}		1 PCLKH + 3 ADCLK				

Note 1. Refer to Figure 43.31 and Figure 43.32 for illustration of times t_D, t_{SPLSH}, t_{DIAG}, t_{CONV}, and t_{ED}.
Note 2. This is the maximum time required from software writing or trigger input to A/D conversion start.
Note 3. Set tSPLSH + tCONV to satisfy the conversion time conditions listed in the A/D conversion characteristics of section 47, Electrical Characteristics.

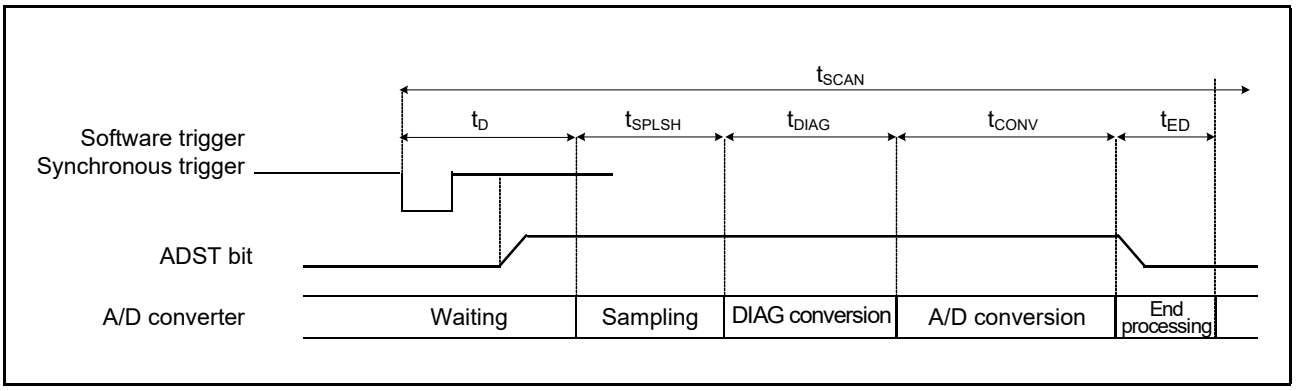


Figure 43.31 Scan Conversion Timing (Activated by Software or Synchronous Trigger Input (MTU3a, GPTa, TPUa, ELC))

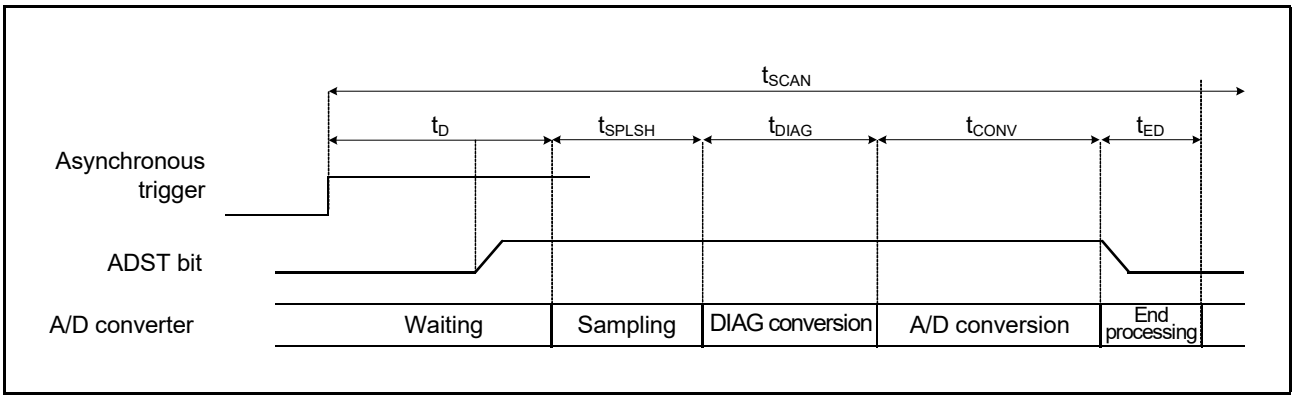

Figure 43.32 Scan Conversion Timing (Activated by Asynchronous Trigger Input (ADTRGn))

43.3.8 Usage Example of A/D Data Register Automatic Clearing Function

In A/D-converted value addition/average mode, the A/D data register automatic clearing function can be used when A/D conversion of the analog input of the selected channels or A/D conversion of the temperature sensor output is selected. Setting the ACE bit in ADCER to 1 automatically clears the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR) to 0000h when the A/D data registers are read by the CPU or DMAC.
This function enables detection of update failures of the A/D data registers (ADDRy, ADRD, ADDBLDR, ADDBLDRA, ADDBLDRB, ADTSDR). The following describes the examples in which the function to automatically clear the ADDRy register is enabled and disabled.
In a case where the ACE bit in ADCER is 0 (automatic clearing is disabled), if the A/D conversion result (0222h) is not written to the ADDRy register for some reason, the old data (0111h) will be the ADDRy value. Furthermore, if this ADDRy value is read into a general register using an A/D scan end interrupt, the old data (0111h) can be saved in the general register. When checking whether there is an update failure, it is necessary to frequently save the old data in the RAM or a general register.
In a case where the ACE bit in ADCER is 1 (automatic clearing is enabled), when ADDRy = 0111h is read by the CPU or DMAC, ADDRy is automatically cleared to 0000h. After that, if the A/D conversion result 0222h cannot be transferred to ADDRy for some reason, the cleared data (0000h) remains as the ADDRy value. If this ADDRy value is read into a general register using an A/D scan end interrupt at this point, 0000h will be saved in the general register. Occurrence of an ADDRy update failure can be determined by simply checking that the read data value is 0000h.

43.3.9 A/D-Converted Value Addition/Average Mode

In A/D-converted value addition mode, the same channel is A/D-converted two to four consecutive times and the sum of the converted values is stored in the data register. In A/D-converted value average mode, the same channel is A/D-converted two to four consecutive times and the mean of the converted values is stored in the data register. The use of the average of these results can improve the accuracy of A/D conversion, depending on the types of noise components that affect A/D conversion. This function, however, cannot always guarantee an improvement in A/D conversion accuracy. The A/D-converted value addition/average mode can be specified when A/D conversion of the channel select analog input or temperature sensor output is selected.

43.3.10 Disconnection Detection Assist Function

This converter incorporates the function to fix the charge for sampling capacitance to the specified state (VREFH0 or VREFL0 for unit 0; VREFH1 or VREFL1 for unit 1) before start of A/D conversion. This function enables disconnection detection in wiring of analog inputs.

Figure 43.33 illustrates the A/D conversion operation when the disconnection detection assist function is used. Figure 43.34 shows an example of disconnection detection when precharge is selected. Figure 43.35 shows an example of disconnection detection when discharge is selected.

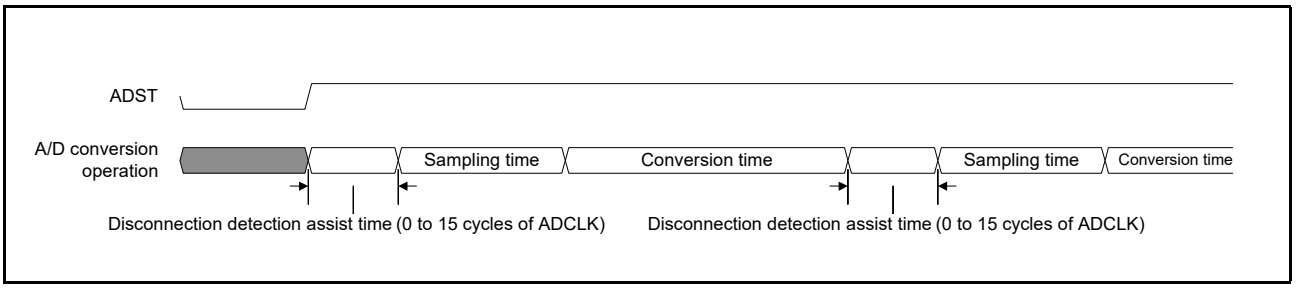

Figure 43.33 Operation of A/D Conversion when the Disconnection Detection Assist Function is Used

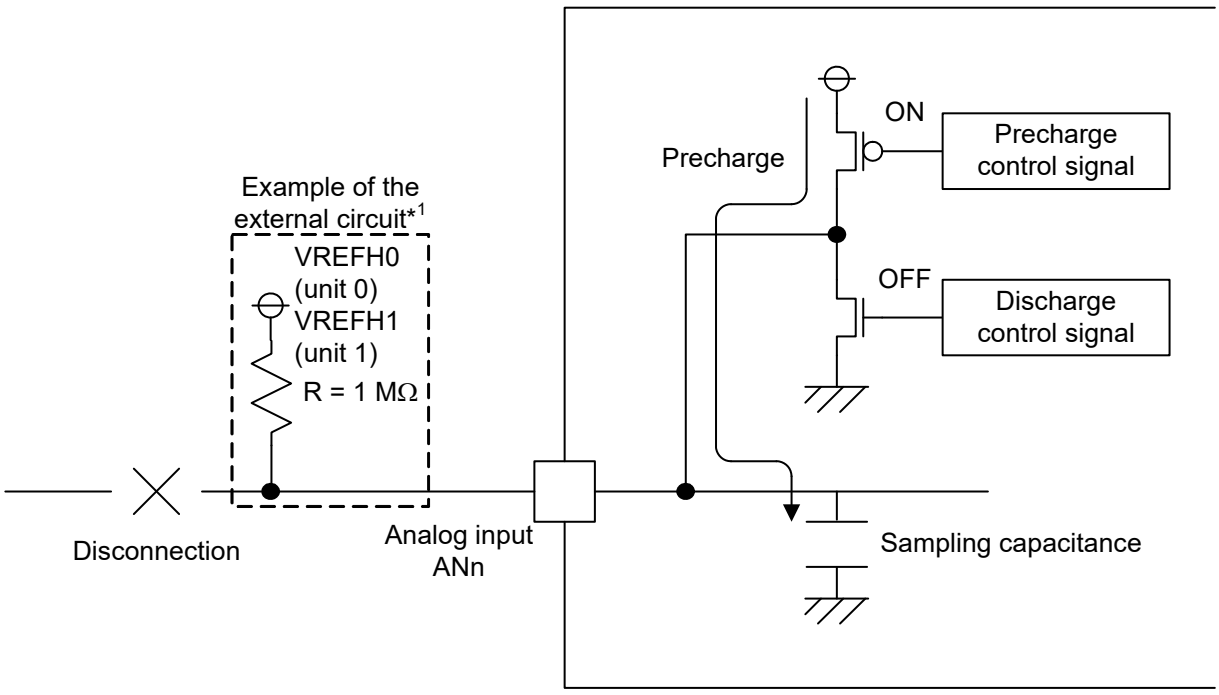
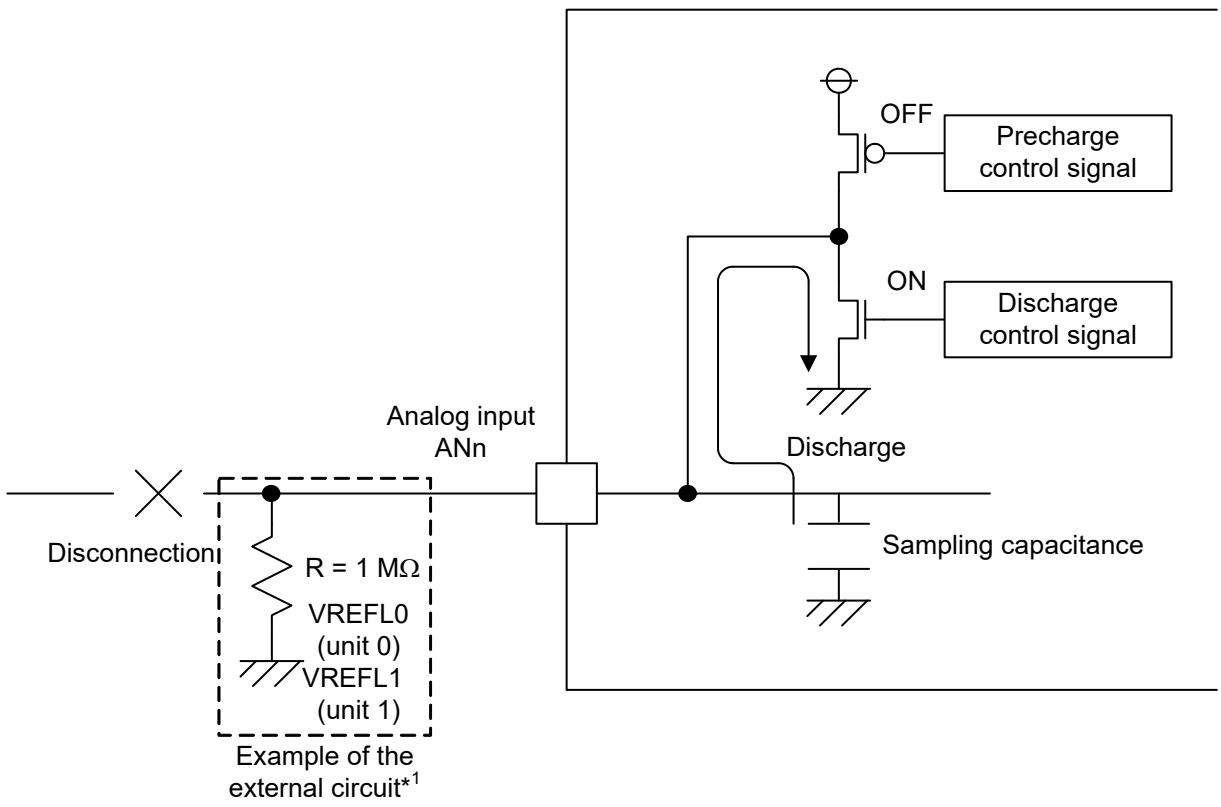


Note 1. The converted result should be used after fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 43.34 Example of Disconnection Detection when Precharge is Selected



Note 1. The converted result should be used after fully evaluated because the result data when disconnection occurs varies depending on the external circuit.

Figure 43.35 Example of Disconnection Detection when Discharge is Selected

43.3.11 Starting A/D Conversion with Asynchronous Trigger

The A/D conversion can be started by the input of an asynchronous trigger. To start up the A/D converter by an asynchronous trigger, the A/D conversion start trigger select bits (ADSTRGR.TRSA[5:0]) should be set to 000000b and a low-level signal should be input to the asynchronous trigger (ADTRGn pin). Both the ADCSR.TRGE and ADCSR.EXTRG bits then should be set to 1. Figure 43.36 shows a timing of the asynchronous trigger input.
For the time between setting the ADST bit to 1 and starting A/D conversion, refer to section 43.5.3 A/D Conversion Restarting Timing and Termination Timing.

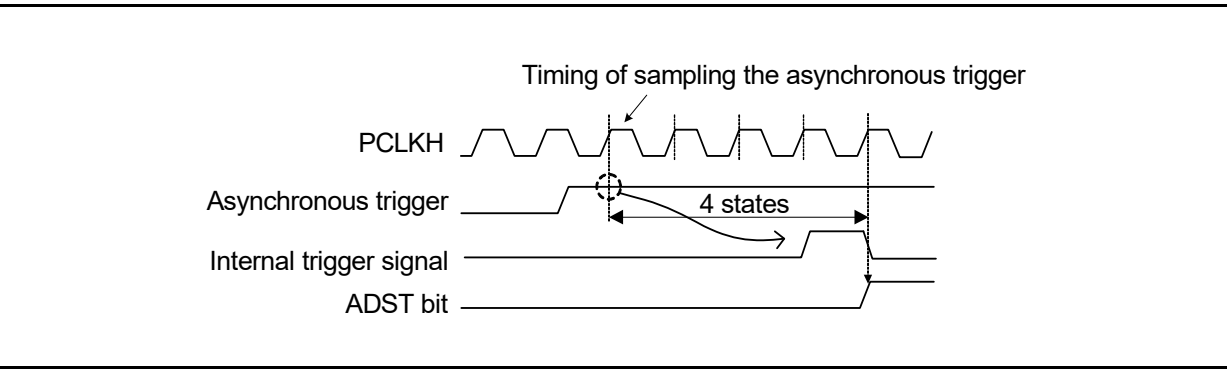


Figure 43.36 Asynchronous Trigger Input Timing

43.3.12 Starting A/D Conversion with Synchronous Trigger from Peripheral Module

The A/D conversion can be started by a synchronous trigger (MTU3a, GPTa, TPUa, ELC). To start the A/D conversion by a synchronous trigger, the ADCSR.TRGE bit should be set to 1, the ADCSR.EXTRG bit should be cleared to 0, and the relevant sources should be selected by the ADSTRGR.TRSA[5:0] and ADSTRGR.TRSB[5:0] bits.

43.3.13 Pin-Level Self-Diagnosis Function

The pin-level self-diagnosis function performs A/D conversion using different voltage levels for input channels with odd numbers and for input channels with even numbers, respectively, to diagnose abnormality of routes from the ANn pins. Different voltage levels can be set in the ADTDCR register, with a combination of AVSS, AVCC, and 1/2 × AVCC. Users can select any physical channels to be tested in the pin-level self-diagnosis function. Furthermore, pin-level self-diagnosis can be performed for all scan operations.

43.3.13.1 Pin-Level Self-Diagnosis in Single Scan Mode (without Channel-Dedicated Sample-and-Hold Circuits)

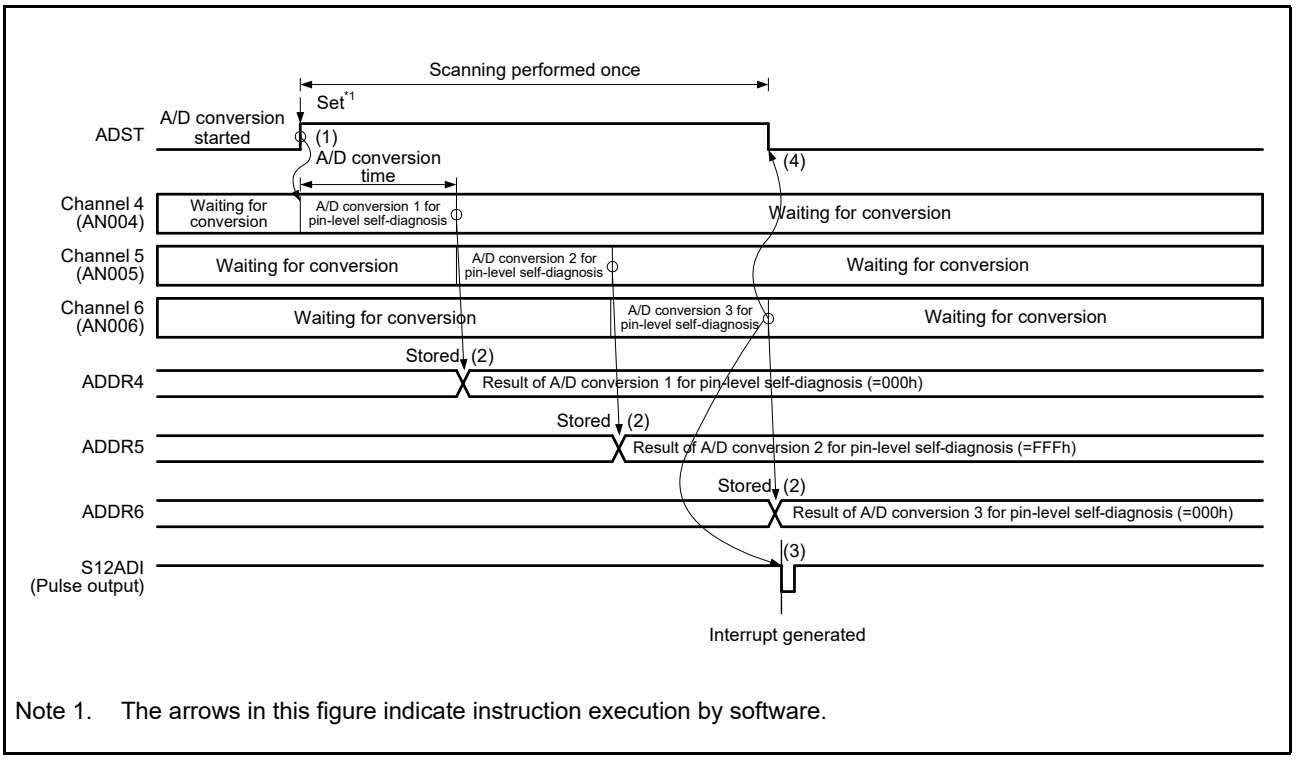
During pin-level self-diagnosis in single scan mode, A/D conversion of the analog input on the specified channel is performed for one cycle only as follows:

(1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the pin with the smallest number n.

(2) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).

(3) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon completion of scanning is enabled).

(4) The ADST bit in ADCSR remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



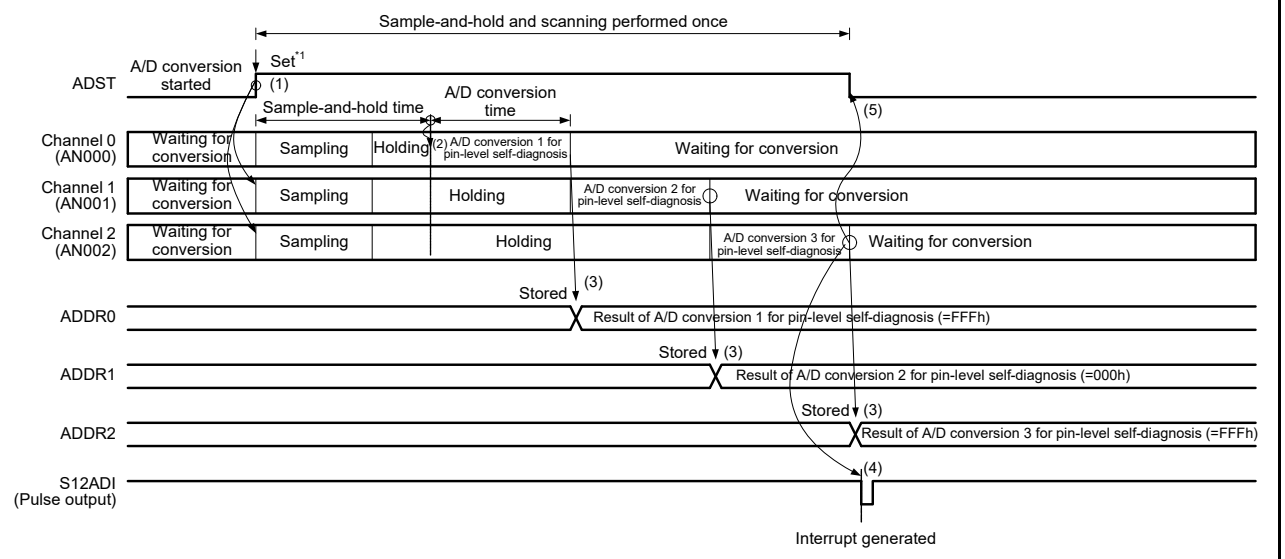
Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.37 Example Operation of Pin-Level Self-Diagnosis in Single Scan Mode (Basic Operation: AN004 to AN006 Selected/ADTDCR.TDLV[1:0] = 00b)

43.3.13.2 Pin-Level Self-Diagnosis in Single Scan Mode (with Channel-Dedicated Sample-and-Hold Circuits)

When pin-level self-diagnosis is performed with the channel-dedicated sample-and-hold circuit used, sample-and-hold operation is first performed, and then A/D conversion is performed once on the analog input of all the selected channels as below. The channels whose channel-dedicated sample-and-hold circuit is to be used can be selected by the SHANS[3:0] bits in ADSHCR.

(1) When the ADST bit in ADCSR is set to 1 (A/D conversion start) by a software trigger, a synchronous trigger input (MTU3a, GPTa, TPUa, ELC), or an asynchronous trigger input, sampling is started for analog input of all the channels that use channel-dedicated sample-and-hold circuit.
(2) After sample-and-hold operation, A/D conversion is performed for ANn pins selected by the ADANSA register, starting from the channel with the smallest number n.
(3) Each time A/D conversion of a single channel is completed, the A/D conversion result is stored into the corresponding A/D data register (ADDRy).
(4) When A/D conversion of all the selected channels is completed, an S12ADI interrupt is generated if the ADIE bit in ADCSR is 1 (S12ADI interrupt upon completion of scanning is enabled).
(5) The ADST bit in ADCSR remains 1 (A/D conversion start) during A/D conversion, and is automatically cleared to 0 when A/D conversion of all the selected channels is completed. Then the 12-bit A/D converter enters a waiting state.



Note 1. The arrows in this figure indicate instruction execution by software.

Figure 43.38 Example Operation of Pin-Level Self-Diagnosis in Single Scan Mode (with Channel-Dedicated Sample-and-Hold Circuits: AN000 to AN002 Selected/ADTDCR.TDLV[1:0] = 01b)

43.3.14 Error Detection Function

The overwrite error detection function detects update of the A/D conversion results held in various A/D data registers, without a need of reading those results. The 12-bit A/D converter can generate S12ADOWEI interrupt, which is an overwrite error interrupt request to the error control module (ECM).

Setting the OWEIE bit in the ADERCR register to 1 enables generation of S12ADOWEI interrupt, and clearing the bit to 0 disables generation of S12ADOWEI interrupt. Reading the ADOWER 0/1 and ADOWEER registers can determine the A/D data register in which the overwrite error occurred. Writing 1 to the OWEC bit in the ADERCLR register clears all the overwrite error flags held in the ADOWER 0/1 and ADOWEER registers.

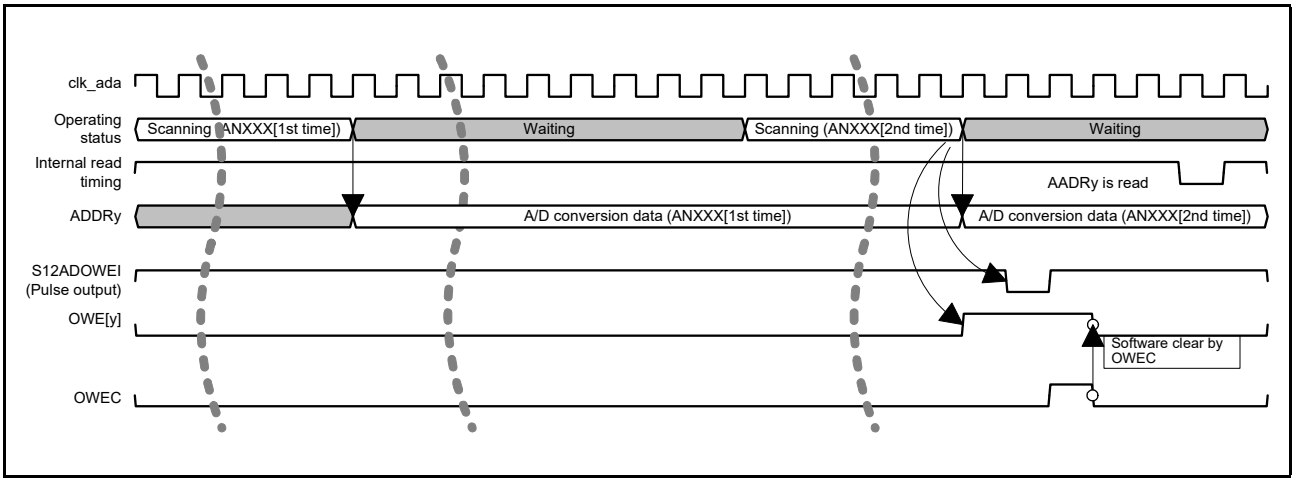


Figure 43.39 Example of Generation of AD Overwrite Error Interrupt

43.4 Interrupt Sources and DMAC Transfer Requests

43.4.1 Interrupt Requests

The 12-bit A/D converter can generate scan end interrupt requests S12ADI and S12GBADI. The module also generates the S12CMPI interrupt in response to matches with a condition for comparison.
Setting the ADCSR.ADIE bit to 1 and 0 enables and disables generation of an S12ADI interrupt, respectively; similarly, setting the ADCSR.GBADIE bit to 1 and 0 enables and disables generation of an S12GBADI interrupt, respectively.
Setting the ADCMPCR.CMPIE bit to 1 and 0 enables and disables generation of an S12CMPI interrupt, respectively.
In addition, the DMAC can be started up when an S12ADI or an S12GBADI interrupt is generated. Using an S12ADI or an S12GBADI interrupt to allow the DMAC to read the converted data enables continuous A/D conversion without burden on software.
For details on DMAC settings, see section 15, DMA Controller (DMACAa).
The S12ADI and S12GBADI interrupts are output according to the settings of scan mode and double trigger mode as shown in Table 43.12.

Table 43.12 Relationship between Mode Setting and S12ADI Interrupt Output

Scan Mode	Double Trigger Mode (DBLE)	Trigger	S12ADI Interrupt (ADIE = 1)	S12GBADI Interrupt (GBADIE = 1)
Single scan mode	DBLE = 0	Software trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Asynchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
	DBLE = 1	Software trigger (setting prohibited)*1	—	—
		Synchronous trigger	Output on completion of each even-order scan	Not output (group B scan is disabled)
		Asynchronous trigger (setting prohibited)*1	—	—
Continuous scan mode	Setting prohibited	Software trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Synchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
		Asynchronous trigger	Output on completion of each scan	Not output (group B scan is disabled)
Group scan mode	DBLE = 0	Software trigger (setting prohibited)*1	—	—
		Synchronous trigger	Output on completion of each scan for group A	Output on completion of each scan for group B
		Asynchronous trigger (setting prohibited)*1	—	—
	DBLE = 1	Software trigger (setting prohibited)*1	—	—
		Synchronous trigger	Output on completion of each even-order scan for group A	Output on completion of each scan for group B
		Asynchronous trigger (setting prohibited)*1	—	—

Note 1. Setting a software trigger and asynchronous trigger in double trigger mode is prohibited.
Setting a software trigger and asynchronous trigger in group scan mode is also prohibited.

43.4.2 Scan End Event Output to ELC

The event link controller (ELC) enables a link operation with the modules specified in advance using S12ADI interrupt request signal as an event signal. The S12GBADI and S12CMPI interrupt request signals cannot be used as an event signal. An event signal can be output regardless of the settings of the corresponding interrupt request enable bits. The 12-bit A/D converter outputs an A/D conversion end event.

43.5 Usage Notes

43.5.1 Notes on Reading Data Registers

The A/D data registers, A/D data duplication registers, A/D data duplication register A, A/D data duplication register B, A/D temperature sensor data register, and A/D self-diagnosis data register must be read in word units. If a register is read twice in byte units, that is, the upper byte and lower byte are separately read, the A/D-converted value having been read first may disagree with the A/D-converted value having been read for the second time.

43.5.2 Notes on Stopping A/D Conversion

To select an asynchronous trigger or a synchronous trigger as the condition for starting A/D conversion and stop A/D conversion, follow the procedure in Figure 43.40.

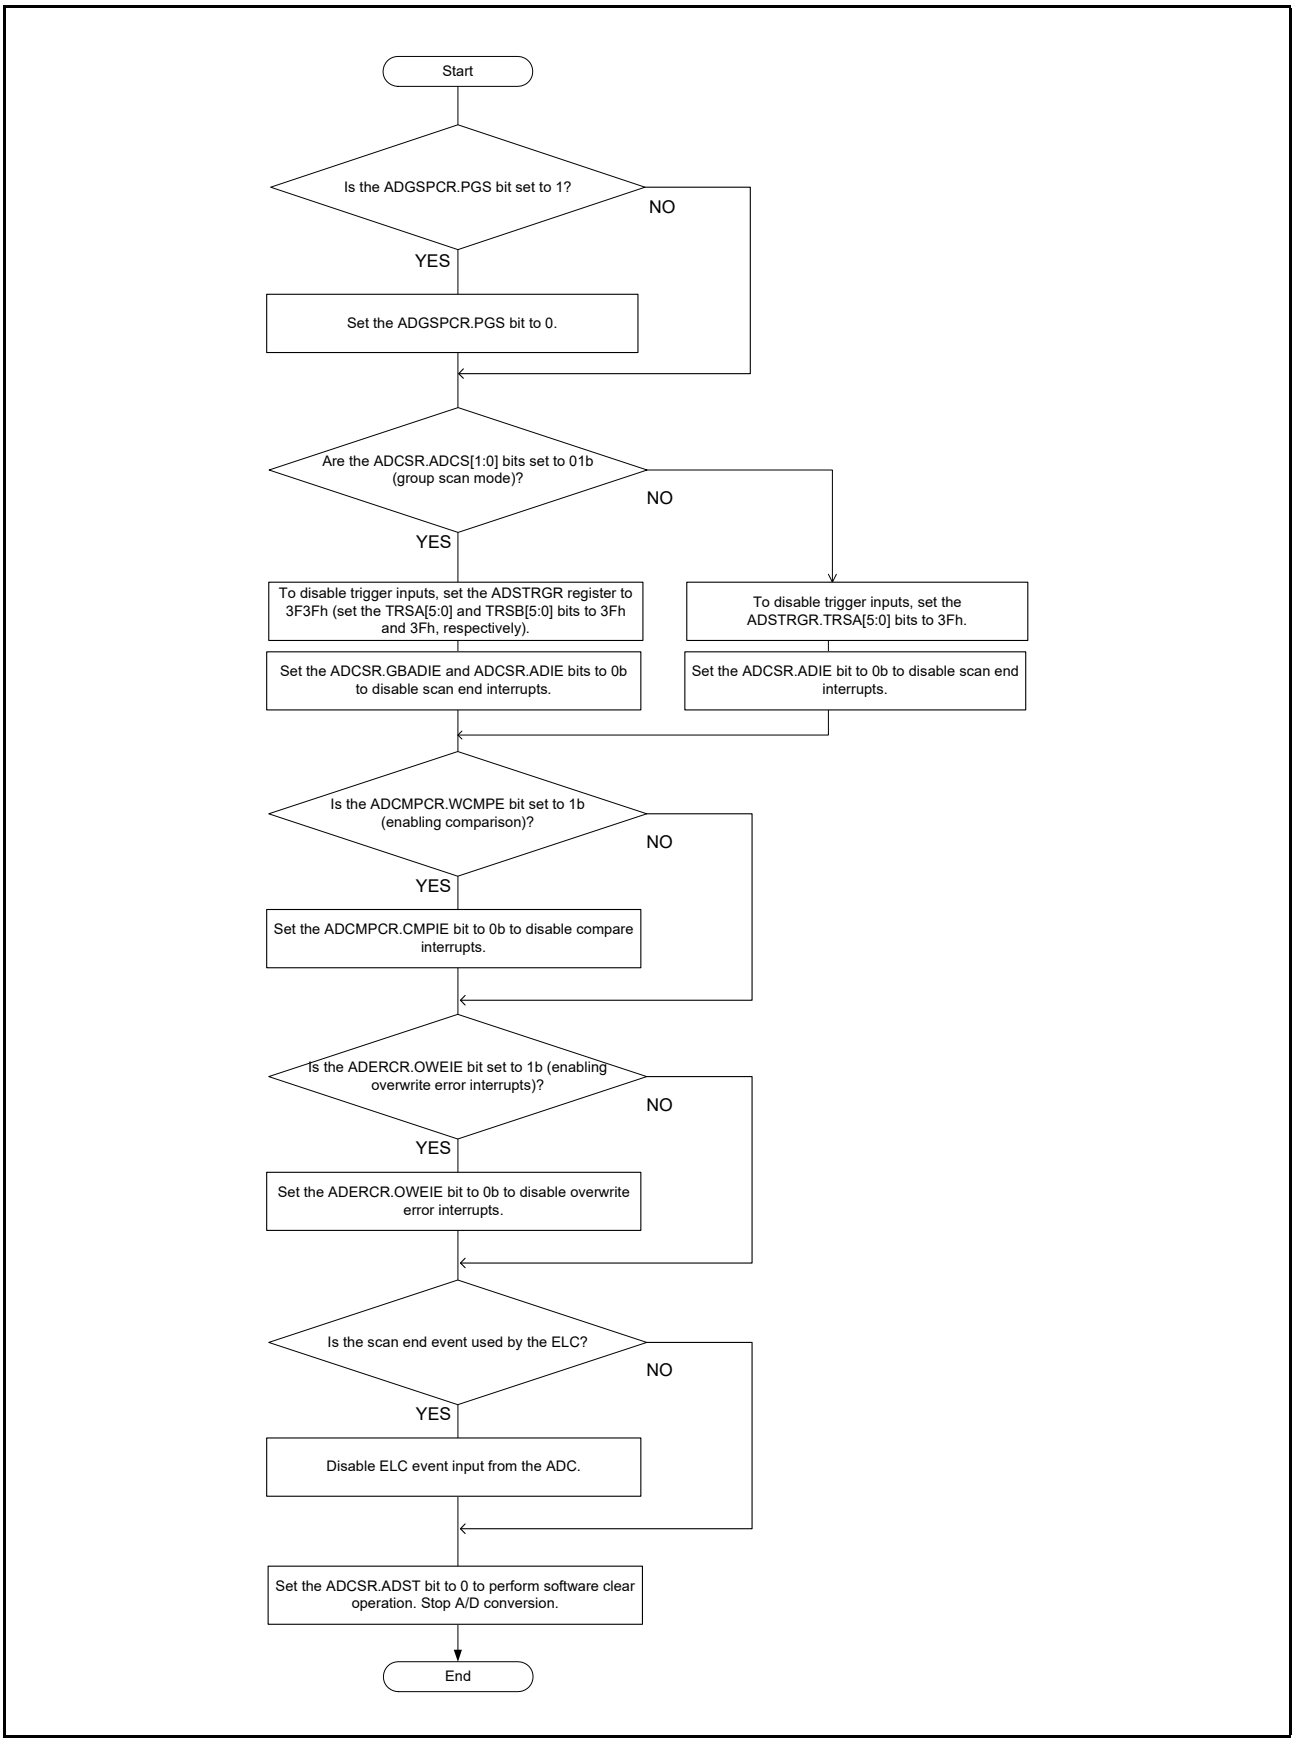

Figure 43.40 Procedures for Clear Operation by Software through the ADCSR.ADST Bit

43.5.3 A/D Conversion Restarting Timing and Termination Timing

It takes a maximum of six ADCLK cycles until the idle analog unit of the 12-bit A/D converter is restarted after the ADST bit in ADCSR is set to 1. It takes a maximum of two ADCLK cycles until the operating analog unit of the 12-bit A/D converter is terminated if the ADST bit in ADCSR is set to 0.

43.5.4 Notes on Scan End Interrupt Handling

When scanning the same analog input twice using any trigger, if the CPU does not complete reading out the A/D-converted data by the time the A/D conversion of the first analog input for the second scan ends after the first scan end interrupt is generated, the first A/D-converted data is overwritten with the second A/D-converted data and an overwrite error occurs.

43.5.5 Module Stop Function Setting

Operation of the 12-bit A/D converter can be disabled or enabled using the module stop control register C (MSTPCRC). The initial setting is for operation of the 12-bit A/D converter to be halted. Releasing the module-stop state enables access to the registers. After release from the module-stop state, wait for at least 1µs before starting A/D conversion. For details, see section 9, Low-Power Consumption Function.

43.5.6 Notes on Entering Low-Power Consumption States

Before the transition to the module-stop state or software standby mode, make sure to stop A/D conversion. Here, set the ADST bit in ADCSR to 0, and secure certain period of time until the analog unit of the 12-bit A/D converter is stopped. Follow the procedure given below to secure this time.
Follow the procedure for clear operation by software through the ADCSR.ADST bit, shown in Figure 43.40. Then, after two clock cycles of ADCLK pass, place the 12-bit A/D converter in the module-stop state or software standby mode.
To place the 12-bit A/D converter in standby mode, set the MSTPCRC.MSTPCRC4 bit (unit 1) or the MSTPCRC.MSTPCRC5 bit (unit 0) to 1.

43.5.7 Caution When Using an External Bus

A/D conversion at the same time as access to an external bus may produce poor results.
Perform A/D conversion several times, eliminate the maximum and minimum values, and obtain the average of the other results.

43.5.8 Error in Absolute Accuracy When Disconnection Detection Assistance is in Use

Using disconnection detection assistance leads to an error in absolute accuracy of the A/D converter. This is because an error voltage is input to the analog input pins due to the resistive voltage division between the pull-up or pull-down resistor (Rp) and the resistance of the signal source (Rs). This error in absolute accuracy is calculated from the following formula. Only use disconnection detection assistance after thorough evaluation.

Maximum error in absolute accuracy (LSB) = 4095 × Rs / Rp

43.5.9 Caution When Using Disconnection Detection Assistance

If ADEXICR.EXSEL[1:0] and ADEXICR.EXOEN are set to any values other than ADEXICR.EXSEL[1:0] = 00b and ADEXICR.EXOEN = 0b, and disconnection detection assistance is enabled, A/D conversion cannot be executed correctly. Be sure to set ADEXICR.EXSEL[1:0] = 00b and ADEXICR.EXOEN = 0b when using disconnection detection assistance. Disable this function when pin-level self-diagnosis is executed.

43.5.10 Caution When Using Self-Diagnosis

If ADEXICR.EXSEL[1:0] and ADEXICR.EXOEN are set to any values other than ADEXICR.EXSEL[1:0] = 00b and ADEXICR.EXOEN = 0b, and self-diagnosis is enabled, A/D conversion cannot be executed correctly. Be sure to set ADEXICR.EXSEL[1:0] = 00b and ADEXICR.EXOEN = 0b when using self-diagnosis
When the channel-dedicated sample-and-hold circuit is to be used for simultaneous sampling of four channels (AN000 to AN003) and self-diagnosis is to be enabled, set the sampling time tSPL to 0.4 µs by using ADSSTR0.SST[7:0] to satisfy the holding characteristics of sample-and-hold circuits, 3.2 µs (max.).

43.5.11 Setting to Restart Conversion by Group B in Group Scan Mode (when Group A is Given Priority)

To enable setting for restarting group B (i.e., PGS = 1 and GBRSCN = 1) in group scan mode (when group A is given priority), set the ratio between the frequency divisors for PCLKH and ADCLK to 1:1. Conversion by group B cannot be restarted in group scan mode (when group A is given priority) unless the frequency division settings are in accord with this.

43.5.12 Allowable Signal Source Impedance

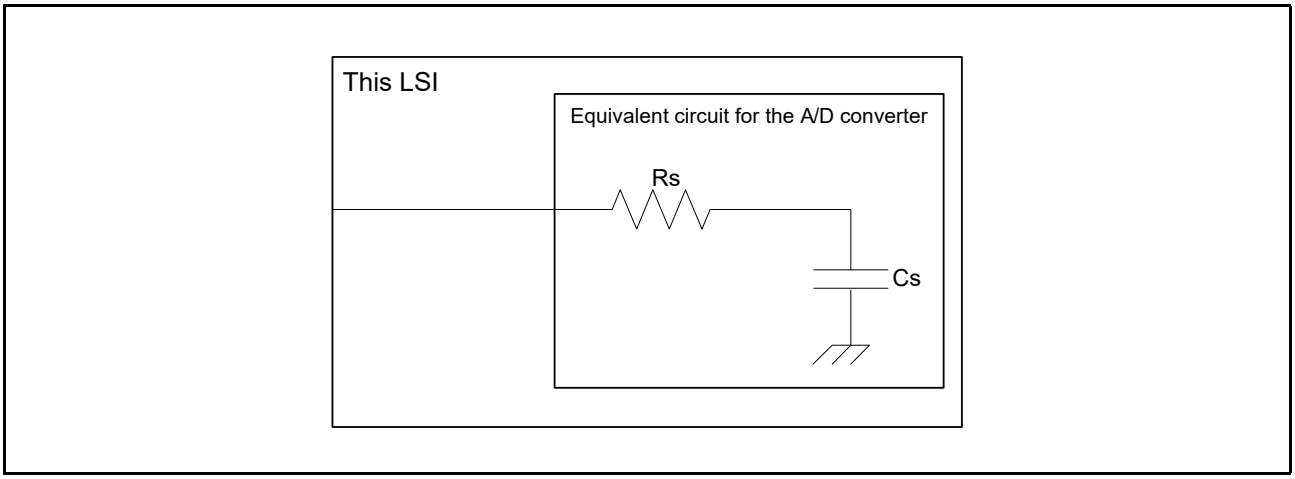

Figure 43.41 Internal Equivalent Circuit for Analog Input Pin

Table 43.13 Analog Pin Specifications

Item		Min.	Typ.	Max.	Unit
Equivalent circuit in ADC unit 0	Rs	—	1.5	—	kΩ
	Cs	—	8	—	pF
Equivalent circuit in ADC unit 1	Rs	—	3.0	—	kΩ
	Cs	—	16	—	pF

Note: As the capacitance estimated from the pin of the product, the pin capacitance listed in section 47, Electrical Characteristics, is included in the internal equivalent circuit.

44. Temperature Sensor

44.1 Overview

This LSI includes a temperature sensor. The temperature sensor outputs a voltage which varies with the temperature. The 12-bit A/D converter (unit 0) can convert the voltage from the sensor into a digital value. The user can then obtain the temperature around this LSI by converting the value into the temperature.
Table 44.1 lists the specifications of the temperature sensor, and Figure 44.1 shows a block diagram of the temperature sensor.

Table 44.1 Specifications of Temperature Sensor

Item	Description
Temperature sensor voltage output	Temperature sensor outputs a voltage to the 12-bit A/D converter (unit 0).
Low-power consumption function	The module-stop state is selectable.

	TSEN	—	—	TSOE	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b4	TSOE	Temperature Sensor Output Enable	0: Disables output from the temperature sensor to the 12-bit A/D converter (unit 0). 1: Enables output from the temperature sensor to the 12-bit A/D converter (unit 0).	R/W
b6, b5	—	Reserved	These bits are read as 0. The write value should be 0.	R/W
b7	TSEN	Temperature Sensor Enable	0: Stops the temperature sensor. 1: Starts the temperature sensor.	R/W

The settings of TSCR register have the timing restrictions shown in Figure 44.3.

44.3 Using the Temperature Sensor

The temperature sensor outputs a voltage which varies with the temperature.
This voltage is converted to a digital value by the 12-bit A/D converter (unit 0). The user can then obtain the temperature around this LSI by converting the value into the temperature.

44.3.1 Preparation for Using the Temperature Sensor

The voltage output by the temperature sensor is proportional to temperature, which can be calculated according to the following formula.

Formula for the temperature characteristic:
T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor at the time of temperature measurement (V)
T1: Temperature experimentally measured at one point (°C)
V1: Voltage output by the temperature sensor at the time of measurement of T1 (V)
T2: Temperature at the experimental measurement of another point (°C)
V2: Voltage output by the temperature sensor at the time of measurement of T2 (V)
Slope: Temperature gradient by the temperature sensor (V/°C); slope = (V2 – V1)/(T2 – T1)

Characteristics vary from sensor to sensor. Therefore, the following experimental measurement at two different temperatures is recommended.
Use the 12-bit A/D converter (unit 0) to measure the voltage V1 output by the temperature sensor at temperature T1. Again, using the 12-bit A/D converter (unit 0), measure the voltage V2 output by the temperature sensor at a different temperature T2. Obtain the temperature gradient (slope = (V2 – V1)/(T2 – T1)) from these results.
Subsequently, obtain temperatures by substituting the slope into the formula for the temperature characteristic (T = (Vs – V1)/slope + T1).

If you are using the temperature gradient given in section 47.7, Temperature Sensor Characteristics, use the 12-bit A/D converter (unit 0) to measure the voltage V1 output by the temperature sensor at temperature T1, and then calculate the temperature characteristic by using the formula below.
However, this method gives less accurate temperatures than measurement at two points.

T = (Vs – V1)/Slope + T1

T: Measured temperature (°C)
Vs: Voltage output by the temperature sensor at the time of temperature measurement (V)
T1: Temperature experimentally measured at one point (°C)
V1: Voltage output by the temperature sensor at the time of measurement of T1 (V)
Slope: Temperature gradient (V/°C) given in section 47.7, Temperature Sensor Characteristics.

- Calculation of the voltage output by the temperature sensor (when AD-converted value addition mode is not selected)
  The voltage output by the temperature sensor (V) can be calculated from the following formula.

$$\text{Output voltage (V)} = \text{AVREFH0 voltage (V)} \times \frac{\text{ADTSDR register value}}{2^n}$$

n: The precision of the AD conversion that is specified by the ADCER.ADPRC[1:0] bits (n = 8, 10, 12).

Remark: When the AD-converted value addition mode is selected, a value corresponding to the number of additions specified by the ADADC register is stored in the ADTSDR register. This requires another calculation of the value calculated from the above formula, i.e., dividing it the specified number of additions.

44.3.2 Setting of 12-Bit A/D Converter (Unit 0)

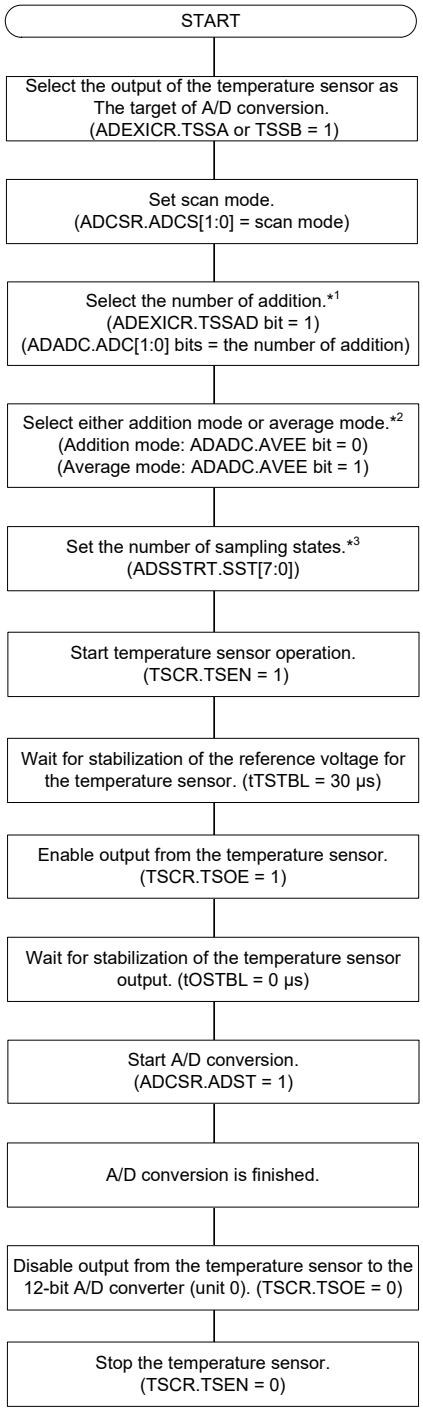
For A/D conversion of temperature sensor output voltages, 12-bit A/D converter (unit 0) registers should be set as follows.

- Setting the Temperature Sensor Voltage as an A/D Conversion Target
  Select A/D conversion of the voltage from the temperature sensor by setting the temperature sensor output A/D conversion select bit in the A/D conversion extended input control register (ADEXICR.TSSA or TSSB) to 1.
- Setting Scan Mode
  Select scan mode by setting the scan mode select bits in the A/D control register (ADCSR.ADCS[1:0]).
- Setting Addition/Average Mode
  For A/D conversion of the temperature sensor output, additional or average mode is selectable. To use either additional or average mode, set the temperature sensor output A/D converted value addition mode select bit in the A/D conversion extended input control register (ADEXICR.TSSAD) to 1, and the addition count select bits in the A/D converted value addition count select register (ADADC.ADC[1:0]) to the desired number of addition. Furthermore, clear the AVEE bit in ADADC to 0 to select addition mode; set the AVEE bit in ADADC to 1 to select average mode. In average mode, however, the ADC[1:0] bits in ADADC should not be set to 10b.
- Setting the Number of Sampling States of the 12-bit A/D converter (unit 0)
  The number of states for sampling of the output of the temperature sensor for A/D conversion is selectable. The initial setting is 11 states. To change the number of states for sampling from 11 states, set the sampling time setting bits in A/D sampling state register T (ADSSTRT.SST[7:0]), when the ADST bit in ADCSR is 0.

Setting the A/D conversion start bit in the A/D control register (ADCSR.ADST) to 1 starts A/D conversion, and the result is stored in the A/D temperature sensor data register (ADTSDR). If you will be using A/D conversion of the output from the temperature sensor, do so in accord with section 44.3.3, Procedure for Using the Temperature Sensor.

44.3.3 Procedure for Using the Temperature Sensor

Figure 44.2 shows the procedure for using the temperature sensor.



Note 1. Unless addition/average mode is set, this setting is not required. To select average mode, do not set the ADC[1:0] bits to 10b.
Note 2. Unless addition/average mode is set, this setting is not required.
Note 3. The initial value for the number of states over which sampling proceeds is 11. If the number of states is not to be changed, this setting is not required.

Figure 44.2 Procedure for Using the Temperature Sensor

44.3.4 Timing of A/D Conversion of Temperature Sensor Output

Figure 44.3 shows the timing from the start of temperature-sensor operation until the completion of A/D conversion when only the output from the temperature sensor is to be A/D converted and conversion is in single-scan mode. The times shown in the figure are described in Table 44.2.

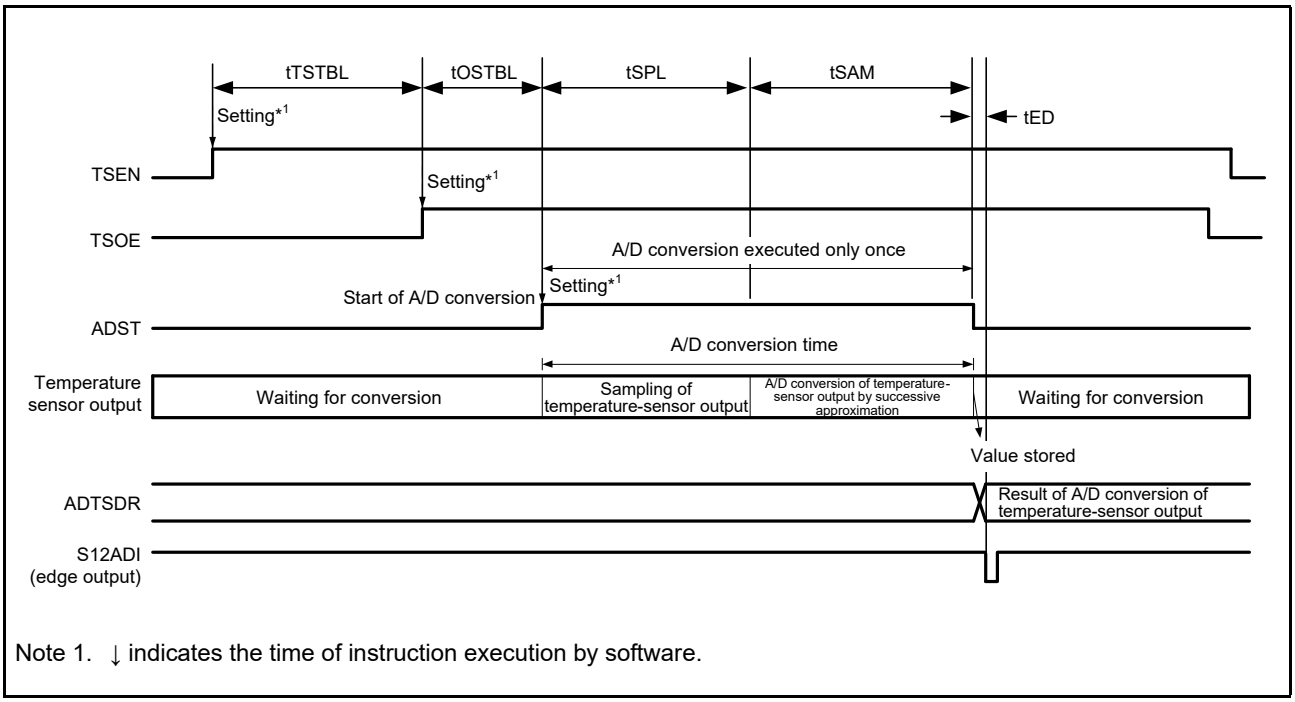


Figure 44.3 Timing from the Start of Temperature-Sensor Operation until Completion of A/D Conversion

Table 44.2 Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation

Item	Symbol	Time
Waiting time for temperature-sensor reference-voltage stabilization	tTSTBL	30 µs (min)
Waiting time for temperature-sensor output stabilization	tOSTBL	0 µs (min)
12-bit A/D converter (unit 0) input sampling time	tSPL	4.25 µs min. ADSSTRT setting × ADCLK cycles
Time for A/D conversion by successive approximation	tSAM	12-bit conversion accuracy: 13 ADCLK 10-bit conversion accuracy: 11 ADCLK 8-bit conversion accuracy: 9 ADCLK
Scan conversion end delay time	tED	1 PCLKH + 3 ADCLK

44.4 Usage Note

44.4.1 Module-Stop Function Setting

The corresponding bit in module stop control register C (MSTPCRC) can be used to enable and disable the temperature sensor. The initial setting is for the temperature sensor to be stopped. The register becomes accessible on release from the module-stop state. For details, see section 9, Low-Power Consumption Function.

45. Data Operation Circuit (DOC)

45.1 Overview

The data operation circuit (DOC) is used to compare, add, and subtract 16-bit data.
Table 45.1 lists the data operation circuit specifications and Figure 45.1 shows a block diagram of the data operation circuit.

- 16-bit data is compared and an interrupt can be generated when a selected condition applies.
- 16-bit data can be added.
- 16-bit data can be subtracted.

Table 45.1 DOC Specifications

Item	Description
Data operation function	16-bit data comparison, addition, and subtraction
Lower power consumption function	Module-stop state can be set.
Interrupts	An interrupt occurs at the following timings: • The compared values either match or mismatch • The result of data addition is greater than FFFFh • The result of data subtraction is less than 0000h
Event link function (event signal output)	An interrupt occurs at the following timings: • The compared values either match or mismatch • The result of data addition is greater than FFFFh • The result of data subtraction is less than 0000h

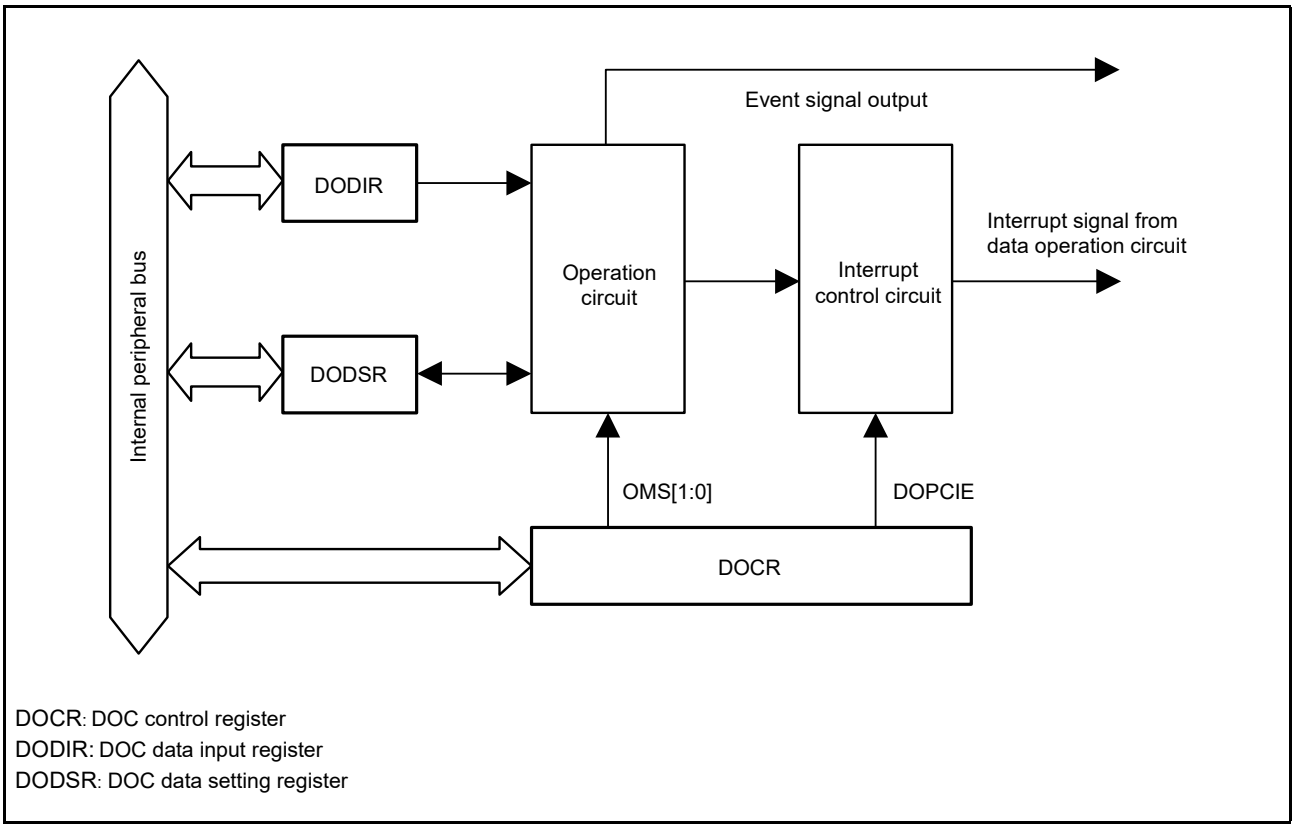

Figure 45.1 Block Diagram of Data Operation Circuit (DOC)

45.2 Register Descriptions

45.2.1 DOC Control Register (DOCR)

The DOCR register controls the DOC.

Address(es): A008 1200h

	b7	b6	b5	b4	b3	b2	b1	b0
	—	DOPCFCL	DOPCF	DOPCIE	—	DCSEL	OMS[1:0]	
Value after reset:	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b1, b0	OMS[1:0]	Operating Mode Select	Selects an operating mode of the data operation circuit. b1 b0 0 0: Data comparison mode 0 1: Data addition mode 1 0: Data subtraction mode 1 1: Setting prohibited	R/W
b2	DCSEL	Detection Condition Select	Selects a condition for detecting data comparison result. 0: Data mismatch is detected. 1: Data match is detected. Note: Valid only in the data comparison mode.	R/W
b3	—	Reserved	This bit is read as 0. The write value should be 0.	R/W
b4	DOPCIE	Data Operation Circuit Interrupt Enable	Specifies whether to enable or disable data operation circuit interrupt requests. 0: Disables interrupts from the data operation circuit. 1: Enables interrupts from the data operation circuit.	R/W
b5	DOPCF	Data Operation Circuit Flag	[Setting conditions] When any of the following is met: • The condition selected by the DCSEL bit is met. • A result of data addition is greater than FFFFh. • A result of data subtraction is less than 0000h. [Clearing condition] Writing 1 to the DOPCFCL bit	R
b6	DOPCFCL	DOPCF Clear	Setting this bit to 1 clears the DOPCF flag of this register. This bit is always read as 0. Writing 0 to this bit has no effect. Only 1 can be written to it.	R/W
b7	—	Reserved	This bit is read as 0. The write value should be 0.	R/W

45.2.2 DOC Data Input Register (DODIR)

The DODIR register is a 16-bit readable/writable register in which 16-bit data for use in operations are stored.

Address(es): A008 1202h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

45.2.3 DOC Data Setting Register (DODSR)

The DODSR register is a 16-bit readable/writable register. This register stores 16-bit data for use as a reference in data comparison mode. This register also stores the results of operations in data addition and data subtraction modes.

Address(es): A008 1204h

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

45.3 Operation

45.3.1 Data Comparison Mode

Figure 45.2 shows an example of the steps involved in data comparison mode operation by the data operation circuit. The following is an example of operation when DCSEL is set to 0 (data mismatch is detected as a result of data comparison).

(1) Writing 00b to the DOCR.OMS[1:0] bits selects data comparison mode.
(2) The 16-bit reference data is set in DODSR.
(3) 16-bit data for comparison is written to DODIR.
(4) Writing of 16-bit data continues until all data for comparison have been written to DODIR.
(5) If a value written to DODIR does not match that in DODSR, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0000h), the DOCR.DOPCF flag does not change to 1 if a value other than 0000h is set in the DODSR register. To perform data comparison, set the DODSR register and write a value to the DODIR register. If the DODSR register is set again after data comparison, the value remaining in the DODIR register will not be compared again with the value set in the DODSR register. That is, comparison proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

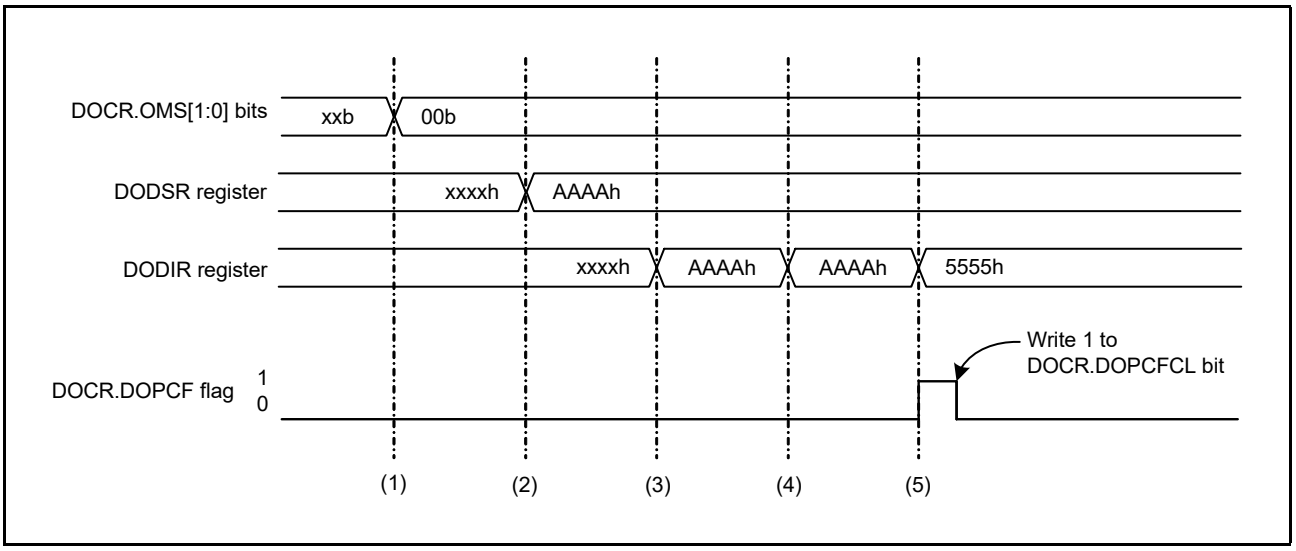

Figure 45.2 Example of Operation in Data Comparison Mode

45.3.2 Data Addition Mode

Figure 45.3 shows an example of the steps involved in data addition mode operation by the data operation circuit.

(1) Writing 01b to the DOCR.OMS[1:0] bits selects data addition mode.
(2) 16-bit data is set in the DODSR register as the value after reset.
(3) 16-bit data to be added is written to DODIR. The result of the operation is stored in DODSR.
(4) Writing of 16-bit data continues until all data for addition have been written to DODIR.
(5) If the result of an operation is greater than FFFFh, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0000h), data addition is not performed if a value other than 0000h is set in the DODSR register. To perform data addition, set the DODSR register and write a value to be added into the DODIR register. If the DODSR register is set again after data addition, the value remaining in the DODIR register will not be added again to the value set in the DODSR register. That is, addition proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

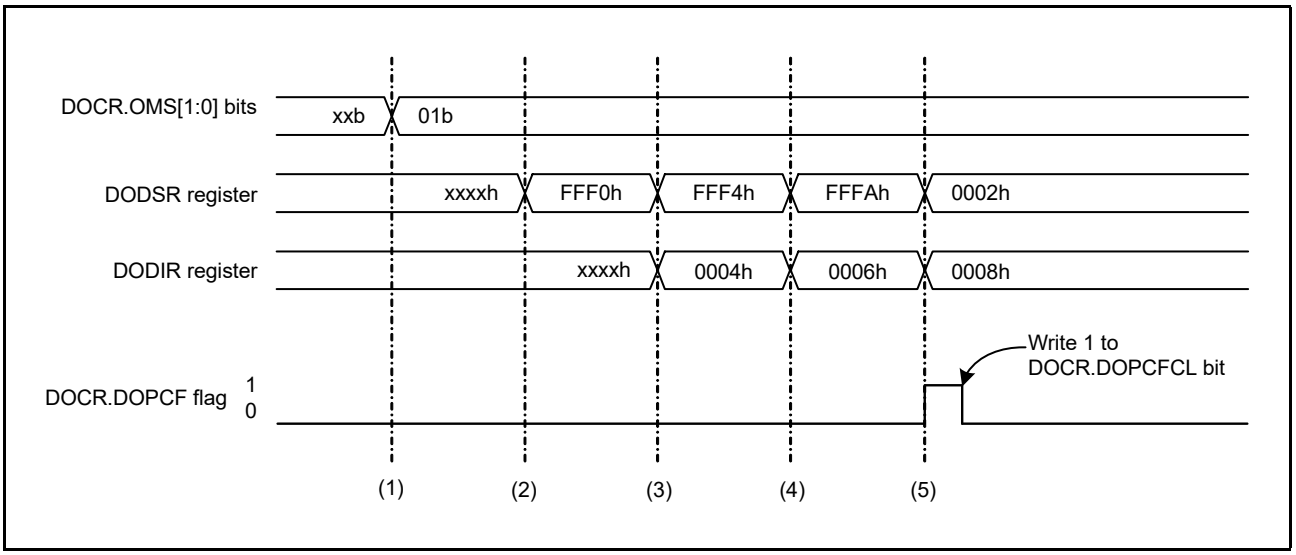

Figure 45.3 Example of Operation in Data Addition Mode

45.3.3 Data Subtraction Mode

Figure 45.4 shows an example of the steps involved in data subtraction mode operation by the data operation circuit.

(1) Writing 10b to the DOCR.OMS[1:0] bits selects data subtraction mode.
(2) 16-bit data is set in the DODSR register as the value after reset.
(3) 16-bit data to be subtracted is written to DODIR. The result of the operation is stored in DODSR.
(4) Writing of 16-bit data continues until all data for subtraction have been written to DODIR.
(5) If the result of an operation is less than 0000h, the DOCR.DOPCF flag is set to 1. When the DOCR.DOPCIE bit is 1, a data operation circuit interrupt is also generated.

Note: When the DODIR register has the value after reset (0000h), data subtraction is not performed if a value other than 0000h is set in the DODSR register. To perform data subtraction, set the DODSR register and write a value to be subtracted into the DODIR register. If the DODSR register is set again after data subtraction, the value remaining in the DODIR register will not be subtracted again from the value set in the DODSR register. That is, subtraction proceeds in response to writing to the DODIR register but not in response to writing to the DODSR register.

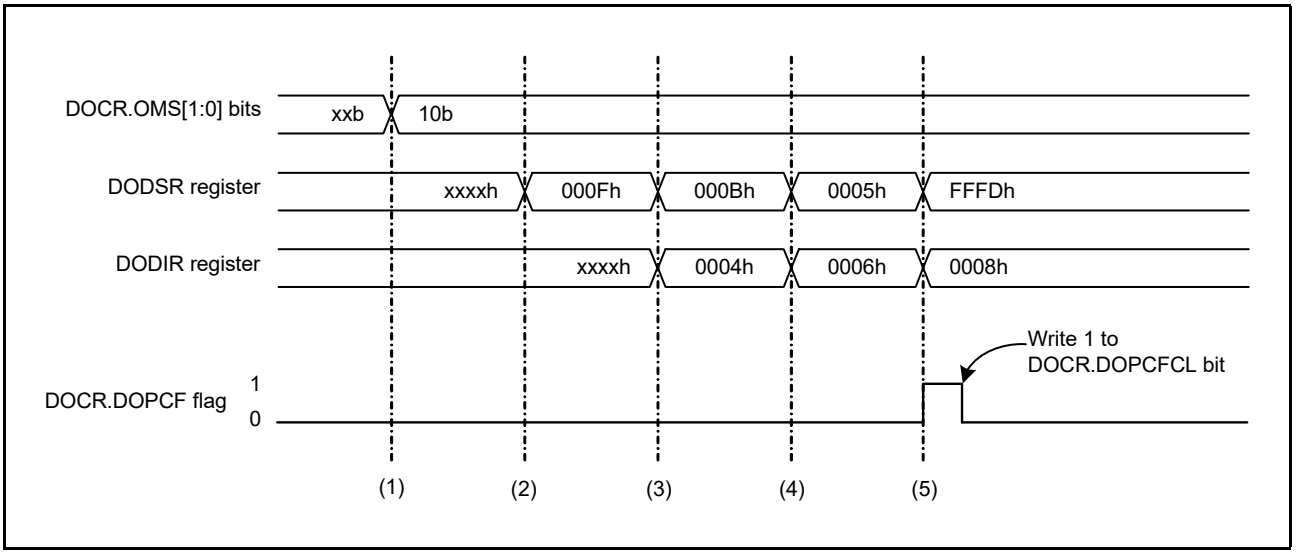

Figure 45.4 Example of Operation in Data Subtraction Mode

45.4 Interrupt Requests

The data operation circuit generates the data operation circuit interrupt as an interrupt request. When an interrupt source is generated, the data operation circuit flag (DOCR.DOPCF) corresponding to the interrupt is set to 1. Table 45.2 describes the interrupt request.

Table 45.2 Interrupt Request from Data Operation Circuit

Interrupt Request	Data Operation Circuit Flag	Interrupt Generation Timing
Data operation circuit interrupt	DOPCF	• The result of data addition is greater than FFFFh • The result of data subtraction is less than 0000h • The compared values either match or mismatch

Note: The data operation circuit interrupt is not conveyed to the interrupt controller, but it is conveyed to the error control module (ECM) as a DOC operation error.

45.5 Event Link Output

The DOC outputs event signals for the event link controller (ELC) under the following conditions, and these can be used to initiate operations by other modules selected in advance.

- The compared values either match or mismatch
- The result of data addition is greater than FFFFh
- The result of data subtraction is less than 0000h

45.5.1 Interrupt Handling and Event Linking

The data operation circuit (DOC) has a bit (DOCR.DOPCIE) to enable or disable interrupts. An interrupt request signal is output for the CPU when an interrupt source is generated while the corresponding enable bit is enabled.
In contrast, an event link output signal is sent to other modules as an event signal via the ELC when an interrupt source is generated, regardless of the setting of the corresponding interrupt enable bit.

45.6 Usage Note

45.6.1 Module Stop Function Setting

Operation of the data operation circuit can be disabled or enabled using module stop control register C (MSTPCRC). The value after reset indicates that the data operation circuit is in the stop state. Register access is enabled by canceling the module-stop state. For details, see section 9, Low-Power Consumption Function.

46. RAM (Product Option)

This LSI has on-chip high-speed RAM (with ECC error correction). The RAM, whose capacity is 1 Mbyte (512 Kbytes × 2), is installed.

46.1 Overview

Table 46.1 lists the specifications of the RAM.

Table 46.1 Specifications of RAM

Item	Description
RAM capacity	1 Mbyte
RAM addresses (for access from the Cortex-R4)	On-chip extended SRAM (area 1) 0400 0000h to 0407 FFFFh 2400 0000h to 2407 FFFFh (mirror) On-chip extended SRAM (area 2) 2000 0000h to 2007 FFFFh 2200 0000h to 2207 FFFFh (mirror)
RAM addresses (for products incorporating an R-IN engine) (for access from the Cortex-M3)	Instruction RAM 0000 0000h to 0007 FFFFh 0400 0000h to 0407 FFFFh (mirror) Data RAM 2000 0000h to 2007 FFFFh
Low-power consumption function	Operate only during access
Error checking	1-bit error correction, 2-bit error detection: The ECC decoder must be enabled to use these functions.
Initializing function	All areas of RAM are initialized to zero by a reset.

Note: The RAM is reset by the sources from the RES# pin input, the ECM, and software.

46.2 Register Descriptions

46.2.1 Protect Command Register (RAMPCMD)

The RAMPCMD register is used to provide write protection for registers that might seriously affect the system in order to prevent the application system from inadvertently stopping due to, for example, runaway of a program. Writing to the protected registers is disabled unless the PROTREL bit is set to 1.

Address(es): A00F 3000h
For access from the Cortex-M3
400F 3000h (for products incorporating an R-IN engine)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	PROTREL
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	PROTREL	Enable Write Access to Protected Registers	1: Write access is enabled. 0: Write access is disabled (protected status).	R/W

To set the PROTREL bit of the RAMPCMD register to 1, the sequence shown below must be used. No special sequence is required to clear this bit to 0 or to read the register.

1. Write 0000 00A5h to the RAMPCMD register as a specific value.
2. Write 0000 0001h to the RAMPCMD register.
3. Write 0000 FFFEh to the RAMPCMD register.
4. Write 0000 0001h to the RAMPCMD register.

Note 1. In steps 1, 2, and 3, nothing is written to the register.
Note 2. Be sure to clear the PROTREL bit to 0 after writing to target registers is completed.

Table 46.2 Write-Protection Target Registers

Register Name	Symbol	R/W
Protect command register	RAMPCMD	R/W
ECC decoder configuration register	RAMEDC	R/W
ECC encoder configuration register	RAMEEC	R/W

46.2.2 ECC Decoder Configuration Register (RAMEDC)

Note: For products incorporating an R-IN engine, see section 46.2.3, ECC Decoder Configuration Register (RAMEDC) (for Products Incorporating an R-IN Engine).

The RAMEDC register controls the ECC decoders for the on-chip extended SRAM (areas 1 and 2).

Address(es): A00F 3100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC_ENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECC_ENABLE	ECC Decoder Enable	0: ECC decoder is disabled. 1: ECC decoder is enabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

When the RAMEDC.ECC_ENABLE bit is set to 1, ECC decoder logic for the on-chip extended SRAM (areas 1 and 2) is enabled, and the following functions are enabled, and this is conveyed to the error control module (ECM).

- 1-bit ECC error: Corrects the read data and conveys the error to the error control module (ECM).
- 2-bit ECC error: Conveys the error to the error control module (ECM).

When the RAMEDC.ECC_ENABLE bit is set to 0 (the “disabled” setting), even if an ECC error occurs, read data is not corrected or the error signal is not conveyed to the ECM. Therefore, retention of the status in the RAMDBEST register, capturing an error address in the RAMDBEAD register, and error count in the RAMDBECNT register are disabled.

Note 1. Switch this register while no masters are accessing the RAM.

Note 2. Writing to this register is disabled unless the write-protection is canceled by the RAMPCMD register.

46.2.3 ECC Decoder Configuration Register (RAMEDC) (for Products Incorporating an R-IN Engine)

The RAMEDC register controls the ECC decoders for instruction RAM and data RAM.

Address(es): 400F 3100h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	ECC_ENABLE
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	ECC_ENABLE	ECC Decoder Enable	0: ECC decoder is disabled. 1: ECC decoder is enabled.	R/W
b31 to b1	—	Reserved	These bits are read as 0. The write value should be 0.	R/W

When the RAMEDC.ECC_ENABLE bit is set to 1, ECC decoder logic for instruction RAM and data RAM are enabled, and the following functions are enabled, and this is conveyed to the error control module (ECM).

- For 1-bit ECC error: Correct the read data, and generate a 1-bit ECC error interrupt from the on-chip extended SRAM, and convey the interrupt signal to the error control module (ECM).
- For 2-bit ECC error: Generate a 2-bit ECC error interrupt from the on-chip extended SRAM and convey the interrupt signal to the error control module (ECM).

When the RAMEDC.ECC_ENABLE bit is set to 0 (the “disabled” setting), even if an ECC error occurs, read data is not corrected or the error signal is not conveyed to the ECM. Therefore, retention of the status in the RAMDBEST register, capturing an error address in the RAMDBEAD register, and error count in the RAMDBECNT register are disabled.

Note 1. Switch this register while no masters are accessing the RAM.

Note 2. Writing to this register is disabled unless the write-protection is canceled by the RAMPCMD register.

46.2.4 ECC Encoder Configuration Register (RAMEEC)

Note: For products incorporating an R-IN engine, see section 46.2.5, ECC Encoder Configuration Register (RAMEEC) (for Products Incorporating an R-IN Engine).

The RAMEEC register controls the self-test for the ECC circuit of the on-chip extended SRAM (areas 1 and 2).

If the RAMEEC.DBE_DISTn (n = 0 to 15) bit is set to 1, the Syndrome value (ECC redundancy bit data) is latched when the RAM corresponding to each bit is accessed. Then, when the RAM is accessed the next time, the latched Syndrome value is written to the RAM to inject an ECC error.

If the RAMEEC.DBE_DISTn (n = 0 to 15) bit is set to 0, the normal Syndrome value is always written to the RAM corresponding to each bit.

Address(es): A00F 3104h

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0

Note 1. Switch this register while no masters are accessing the RAM.
Note 2. Writing to this register is disabled unless the write-protection is canceled by the RAMPCMD register.

46.2.5 ECC Encoder Configuration Register (RAMEEC) (for Products Incorporating an R-IN Engine)

The RAMEEC register controls the self-test for the ECC circuit of the instruction RAM and data RAM.
If the RAMEEC.DBE_DISTn (n = 0 to 15) bit is set to 1, the Syndrome value (ECC redundancy bit data) is latched when the RAM corresponding to each bit is accessed. Then, when the RAM is accessed the next time, the latched Syndrome value is written to the RAM to inject an ECC error.
If the RAMEEC.DBE_DISTn (n = 0 to 15) bit is set to 0, the normal Syndrome value is always written to the RAM corresponding to each bit.

Note 2. Writing to this register is disabled unless the write-protection is canceled by the RAMPCMD register.

46.2.6 2-Bit ECC Error Status Register (RAMDBEST)

Note: For products incorporating an R-IN engine, see section 46.2.7, 2-Bit ECC Error Status Register (RAMDBEST) (for Products Incorporating an R-IN Engine).

The RAMDBEST register indicates the 2-bit ECC error status for the on-chip extended SRAM (areas 1 and 2). After the error signal is conveyed to the error control module (ECM), read this register to identify the BANK and WAY in which a 2-bit ECC error occurred.

b31 to b16	—	Reserved	These bits are read as 0.	R

Note 1. Reading this register clears the ECC error source.

46.2.7 2-Bit ECC Error Status Register (RAMDBEST) (for Products Incorporating an R-IN Engine)

The RAMDBEST register indicates the 2-bit ECC error status for the instruction RAM and data RAM.
After a 2-bit ECC error interrupt is generated from the on-chip extended SRAM or the error signal is conveyed to the error control module (ECM), read this register to identify the BANK and WAY in which a 2-bit ECC error occurred.

b31 to b16	—	Reserved	These bits are read as 0.	R

Note 1. Reading this register clears the ECC error source.

46.2.8 2-Bit ECC Error Address Register (RAMDBEAD)

Note: For products incorporating an R-IN engine, see section 46.2.9, 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine).

The RAMDBEAD register is a read-only register that holds the address where a 2-bit ECC error was found.

When a 2-bit ECC error is detected, the ECC error generation address is captured with the detection signal as a trigger, and then is stored in the ADDRESS[15:0] bits.

The register in which an ECC error generation address has been captured cannot retain the next ECC error generation address unless the LOCK bit of the register is enabled and the register is read. Therefore, if you want to capture a new ECC error generation address, you must first read this register.

Address(es): A00F 310Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	BANK[1:0]		ADDRESS[15:0]

	ADDRESS[15:0]														—	LOCK
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LOCK	Lock Enable	0: Register unlocked (2-bit ECC error generation address can be captured.) 1: Register locked (2-bit ECC error generation address cannot be captured.) Read this register to unlock the registers.	R
b1	—	Reserved	This bit is read as 0.	R
b17 to b2	ADDRESS [15:0]	2-Bit ECC Error Generation Address	The 2-bit ECC error generation address is retained.	R
b19, b18	BANK[1:0]	2-Bit ECC Error Generation BANK	These bits indicate the number of the bank where a 2-bit ECC error was encountered. 0: On-chip extended SRAM (area 1) BANK0 1: On-chip extended SRAM (area 1) BANK1 2: On-chip extended SRAM (area 2) BANK0 3: On-chip extended SRAM (area 2) BANK1	R
b31 to b20	—	Reserved	These bits are read as 0.	R

Note: If 2-bit ECC errors occur at the same time in different WAYs, the priority of captured addresses is as follows:
On-chip extended SRAM (area 1) BANK0 WAY0 > On-chip extended SRAM (area 1) BANK0 WAY1 >
On-chip extended SRAM (area 1) BANK0 WAY2 > On-chip extended SRAM (area 1) BANK0 WAY3 >
On-chip extended SRAM (area 1) BANK1 WAY0 > On-chip extended SRAM (area 1) BANK1 WAY1 >
On-chip extended SRAM (area 1) BANK1 WAY2 > On-chip extended SRAM (area 1) BANK1 WAY3 >
On-chip extended SRAM (area 2) BANK0 WAY0 > On-chip extended SRAM (area 2) BANK0 WAY1 >
On-chip extended SRAM (area 2) BANK0 WAY2 > On-chip extended SRAM (area 2) BANK0 WAY3 >
On-chip extended SRAM (area 2) BANK1 WAY0 > On-chip extended SRAM (area 2) BANK1 WAY1 >
On-chip extended SRAM (area 2) BANK1 WAY2 > On-chip extended SRAM (area 2) BANK1 WAY3

46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine)

The RAMDBEAD register is a read-only register that holds the address where a 2-bit ECC error was found.
When a 2-bit ECC error is detected, the ECC error generation address is captured with the detection signal as a trigger, and then is stored in the ADDRESS[15:0] bits.
The register in which an ECC error generation address has been captured cannot retain the next ECC error generation address unless the LOCK bit of the register is enabled and the register is read. Therefore, if you want to capture a new ECC error generation address, you must first read this register.

Address(es): 400F 310Ch

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16
	—	—	—	—	—	—	—	—	—	—	—	—	BANK[1:0]		ADDRESS[15:0]	
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

	b15	b14	b13	b12	b11	b10	b9	b8	b7	b6	b5	b4	b3	b2	b1	b0
	ADDRESS[15:0]														—	LOCK
Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b0	LOCK	Lock Enable	0: Register unlocked (2-bit ECC error generation address can be captured.) 1: Register locked (2-bit ECC error generation address cannot be captured.) Read this register to unlock the registers.	R
b1	—	Reserved	This bit is read as 0.	R
b17 to b2	ADDRESS [15:0]	2-Bit ECC Error Generation Address	The 2-bit ECC error generation address is retained.	R
b19, b18	BANK[1:0]	2-Bit ECC Error Generation BANK	These bits indicate the number of the bank where a 2-bit ECC error was encountered. 0: Instruction RAM BANK0 1: Instruction RAM BANK1 2: Data RAM BANK0 3: Data RAM BANK1	R
b31 to b20	—	Reserved	These bits are read as 0.	R

Note: If 2-bit ECC errors occur at the same time in different WAYs, the priority of captured addresses is as follows:
Instruction RAM BANK0 WAY0 > Instruction RAM BANK0 WAY1 >
Instruction RAM BANK0 WAY2 > Instruction RAM BANK0 WAY3 >
Instruction RAM BANK1 WAY0 > Instruction RAM BANK1 WAY1 >
Instruction RAM BANK1 WAY2 > Instruction RAM BANK1 WAY3 >
Data RAM BANK0 WAY0 > Data RAM BANK0 WAY1 >
Data RAM BANK0 WAY2 > Data RAM BANK0 WAY3 >
Data RAM BANK1 WAY0 > Data RAM BANK1 WAY1 >
Data RAM BANK1 WAY2 > Data RAM BANK1 WAY3

46.2.10 2-Bit ECC Error Counter Register (RAMDBECNT)

The RAMDBECNT register is a read-only register that retains the 2-bit ECC error count.
If a 2-bit ECC error is detected, the error counter is incremented with the detection signal as a trigger.
If the counter value exceeds the maximum (Fh), it is cleared to 0h.

Address(es): A00F 3110h
For access from the Cortex-M3
400F 3110h (for products incorporating an R-IN engine)

	b31	b30	b29	b28	b27	b26	b25	b24	b23	b22	b21	b20	b19	b18	b17	b16

Value after reset:	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	Symbol	Bit Name	Description	R/W
b3 to b0	ERRCOUNT [3:0]	2-Bit ECC Error Counter	The 2-bit ECC error count is retained.	R
b31 to b4	—	Reserved	These bits are read as 0.	R

Note: Even if 2-bit ECC errors occur at the same time in different WAYs, the count-up value is 1.

46.3 Description of Operation

46.3.1 Configuration of Memory Map

The instruction RAM and data RAM areas are separate 512-Kbyte RAMs, each having a two-bank four-way configuration.

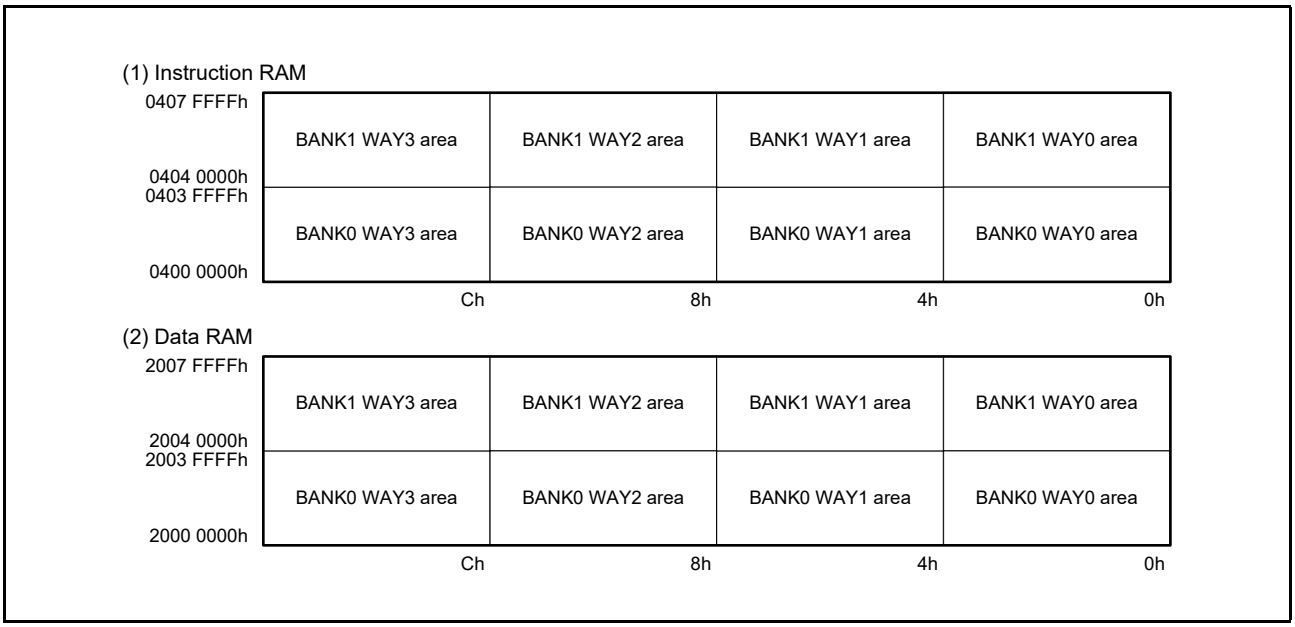

Figure 46.1 Configuration of Memory

46.3.2 ECC Error Correction Function

The RAMEDC register enables or disables ECC error correction in the 1-Mbyte space. ECCs can be used to correct 1-bit errors and detect 2-bit errors. The error control module (ECM) detects the sources of 2-bit errors, and the RAMDBEST register is used to check the way in which an error was found. Moreover, the RAMDBEAD register can be used to identify the address where a 2-bit error was found, and the RAMDBECNT indicates the number of 2-bit errors that have been encountered.

46.3.3 Self-Testing of the ECC Circuit

Self-testing of the ECC circuit proceeds in way units. The RAMEEC register sets the target area for each way. The following shows an example of the procedure for self-testing of the ECC circuit.

(1) Example of ECC error-injection setting procedure

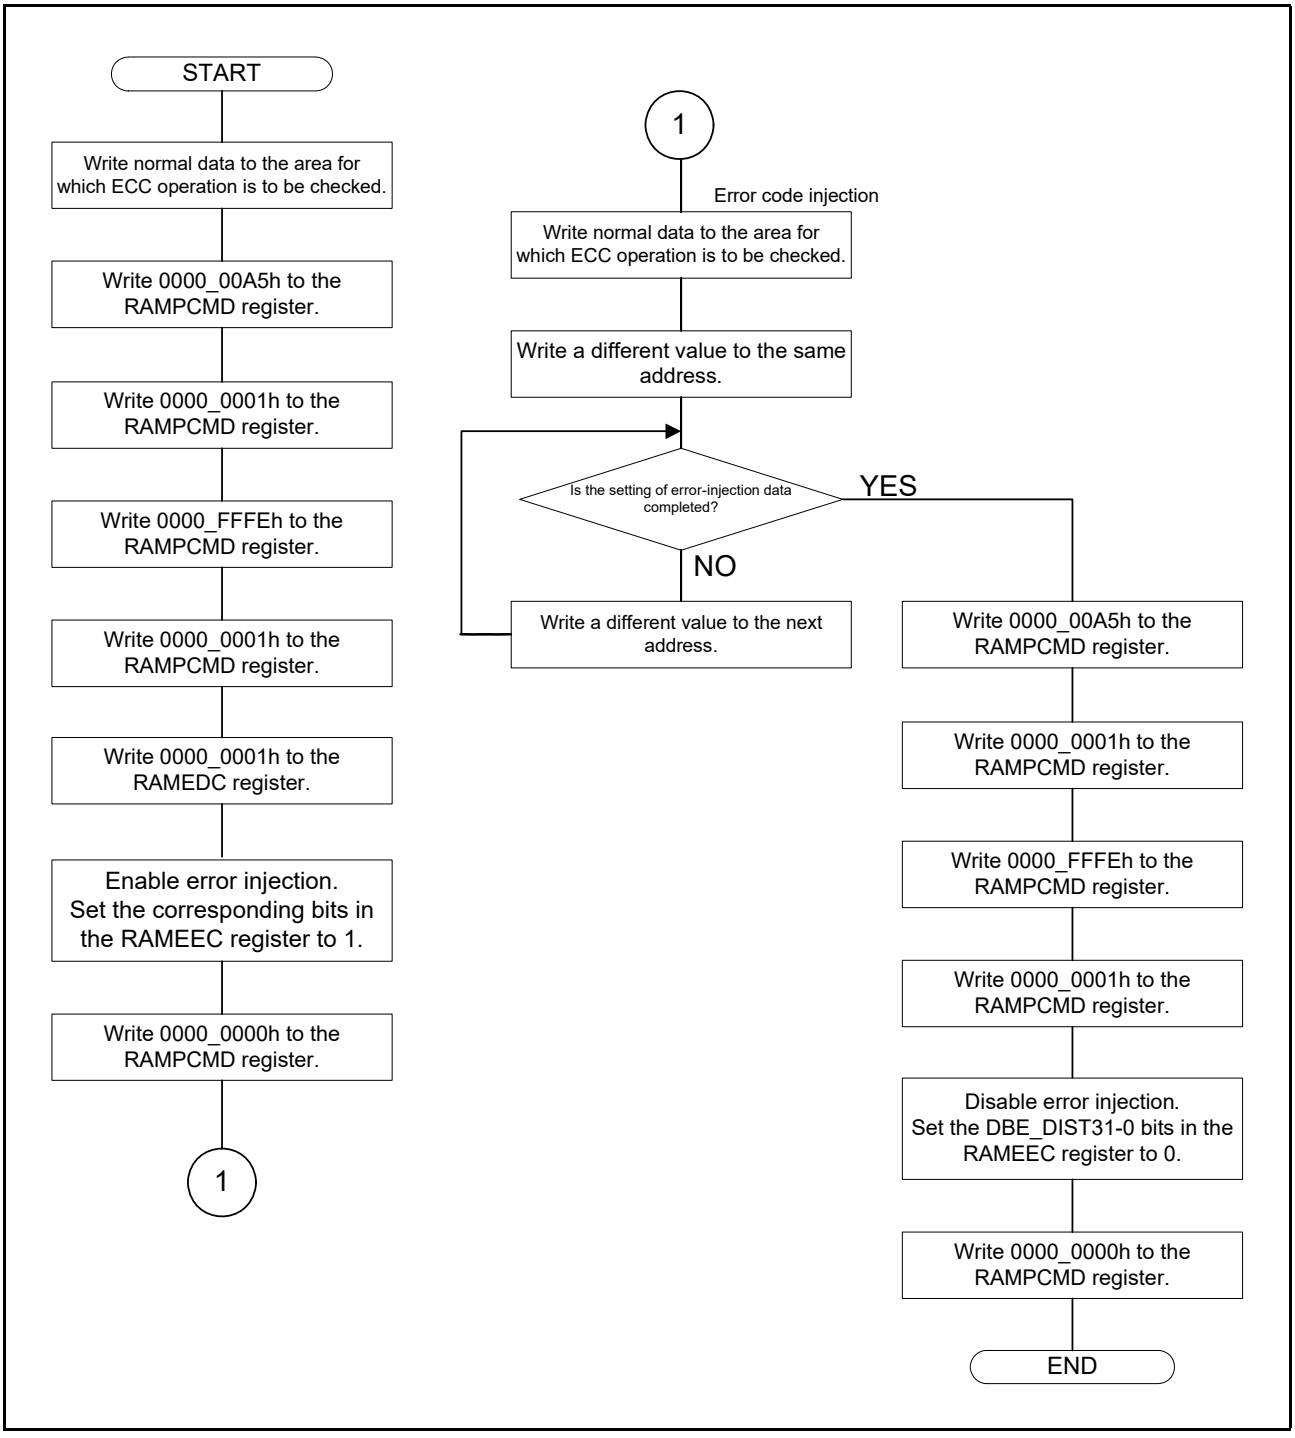

Figure 46.2 Example of ECC Error-Injection Setting Procedure

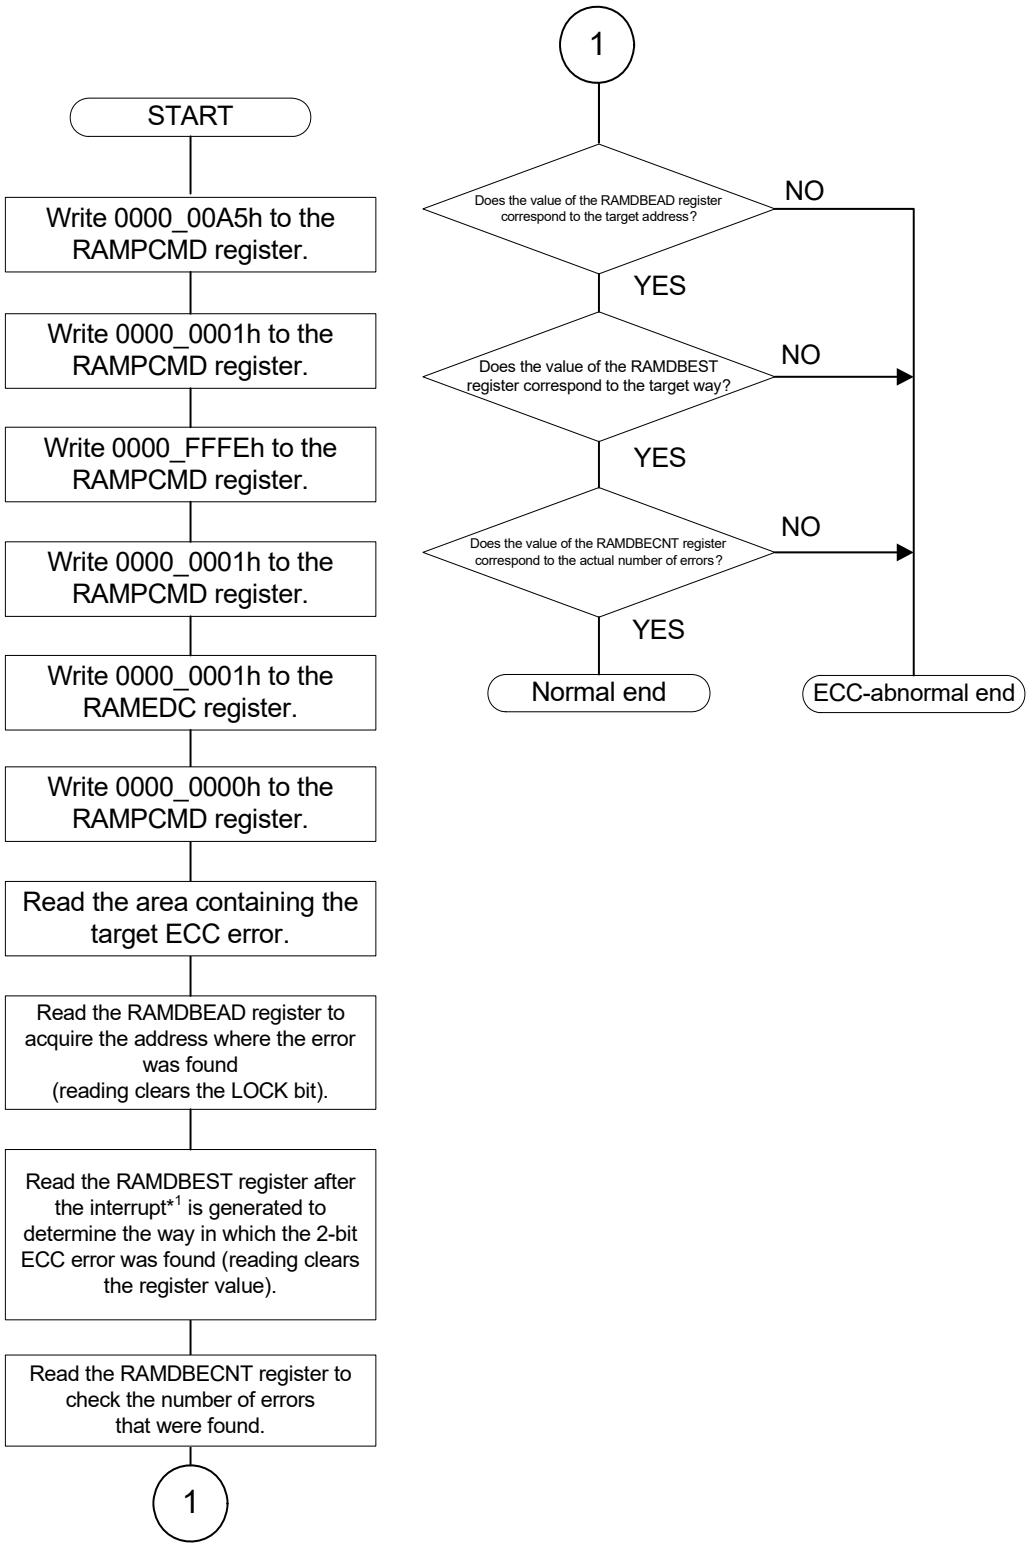
(2) Procedure for Checking ECC Operation



Note 1. For the Cortex-M3, ETHRSE2 interrupt is used to connect the error signal to the NVIC. For the Cortex-R4, the ERRD interrupt via the ECM is used.

Figure 46.3 Procedure of Checking ECC Operation

47. Electrical Characteristics

47.1 Absolute Maximum Ratings

Table 47.1 Absolute Maximum Rating

Conditions: VSS = PLLVSS0 = PLLVSS1 = AVSS0 = AVSS1 = VREFL0 = VREFL1 = VSS_USB = 0 V

Item	Symbol	Value	Unit
Power supply voltage (I/O)	VCCQ33	-0.3 to +4.2	V
Power supply voltage (internal)	VDD	-0.3 to +1.6	V
PLL power supply voltage	PLLVDD0, PLLVDD1	-0.3 to +1.6	V
Input voltage (except for ports for 5-V tolerant*1)	V_{in1}	-0.3 to VCCQ33 + 0.3*5	V
Input voltage (ports for 5-V tolerant*1)	V_{in2}	-0.3 to +5.5*3	V
Analog power supply voltage	AVCC0, AVCC1*2	-0.3 to +4.2	V
Reference power supply voltage	VREFH0, VREFH1	-0.3 to (AVCC0, AVCC1) + 0.3*5	V
USB digital power supply voltage	DVDD_USB	-0.3 to +1.6	V
USB power supply voltage	VDD33_USB*2	-0.3 to +4.2	V
Analog input voltage	V_{AN}	-0.3 to (AVCC0, AVCC1) + 0.3*5	V
Operating temperature (junction temperature)	Tj*4	-40 to +125	°C
Storage temperature	T_{stg}	-55 to +125	°C

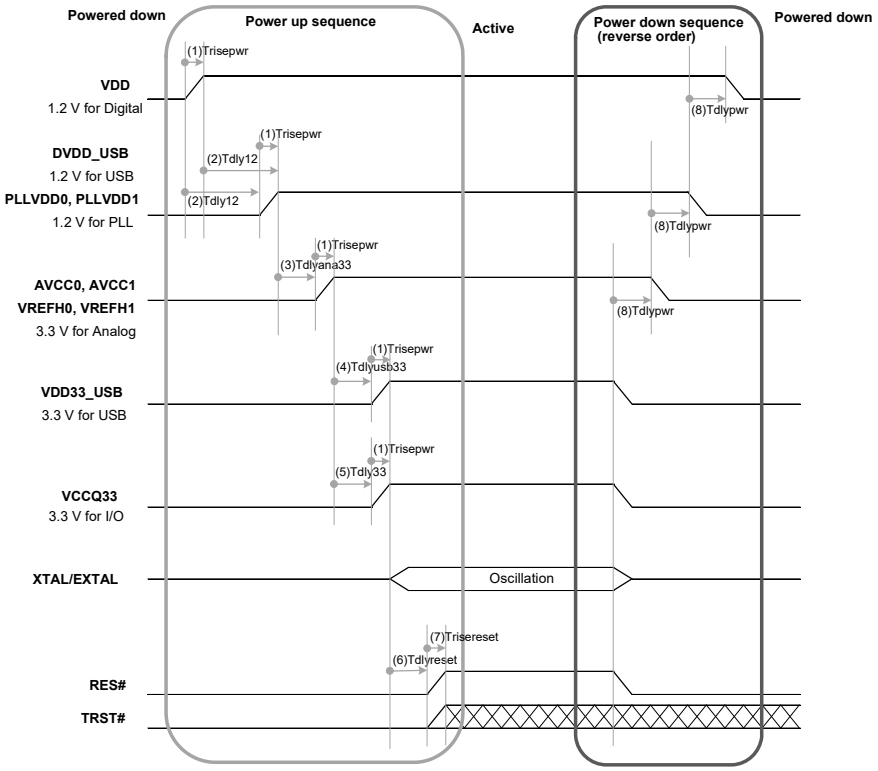
[Usage Notes]

1. Do not directly connect output pins (I/O pins in output state) of IC products to other output pins (including I/O pins in output state) , power pins, or GND pins. However, output pins are directly connectable in an external circuit where timing design is provided to avoid conflict of outputs of high-impedance pins such as I/O pins.
2. If even a single item exceeds the absolute maximum rating for even a moment, it may degrade the product's quality. In other words, the absolute maximum rating is a rated value that potentially causes physical damage to products. Use products with a margin of the absolute maximum rating.
   Specified values and conditions shown in DC characteristics and AC characteristics are the range of normal operation and quality assurance of products.

Note 1. Ports PC0 to PC7 and P30 are 5-V tolerant.
Note 2. When the A/D converter unit 0 is not to be used, connect the AVCC0 and VREFH0 pins to VCCQ33 and the AVSS0 and VREFL0 pins to VSS, respectively. Do not leave these pins open. In the same way, when the A/D converter unit 1 is not to be used, connect the AVCC1 and VREFH1 pins to VCCQ33 and the AVSS1 and VREFL1 pins to VSS, respectively. Do not leave these pins open. When the USB is not to be used, connect the VDD33_USB pin to VCCQ33, the VSS_USB pin to VSS, and the DVDD_USB pin to VDD, respectively. Do not leave these pins open.
Note 3. When VCCQ33 is less than 3.0 V, the rated value of ports for 5-V tolerant is 3.6 V.
Note 4. For operations at the temperatures over 110 °C (junction temperature), refer to the RZ/T1 Group Application Note: Precautions for High-Temperature Operations (R01AN3116).
Note 5. Do not exceed the absolute maximum rating, 4.2 V.

47.2 Power On/Off Sequence

Turn on and off each power supply voltage according to the procedure shown in the figure below.
When turning on the power, be sure to fix TRST# pins and RES# pins to the low level. Otherwise, initialization is not performed successfully.



Timing

		Value		
No.	Item	min	typ	max
(1)	Trisepwr	100 µs	—	50 ms
(2)	Tdly12	0 ms	—	100 ms
(3)	Tdlyana33	0 ms	—	100 ms
(4)	Tdlyusb33	0 ms	—	100 ms
(5)	Tdly33	0 ms	—	100 ms
(6)	Tdlyreset	10 ms	—	—
(7)	Trisereset	—	—	150 µs
(8)	Tdlypwr	0 ms	—	—

Note 1. Turn on all power supply voltages and reset signals with a monotonic increase and turn off with a monotonic decrease.
Note 2. Do not apply a negative voltage to power supply voltages.
Note 3. Before turning on the power, be sure to make reset pins (TRST# and RES#) active (low). Otherwise, inputs and outputs on the pins may be unstable. If this may also be a problem when turning off the power, make reset pins (TRST# and RES#) active (low.)

Note: If the power on/off sequence is not met (out of operation guarantee range), the pin input state and output state may be undefined.

Figure 47.1 Power On/Off Sequence

47.3 DC Characteristics

- Conditions: VDD = PLLVDD0 = PLLVDD1 = DVDD_USB = 1.14 to 1.26 V,
  VCCQ33 = AVCC0 = AVCC1 = VREFH0 = VREFH1 = VDD33_USB = 3.0 to 3.6 V
  VSS = PLLVSS0 = PLLVSS1 = AVSS0 = AVSS1 = VREFL0 = VREFL1 = VSS_USB = 0 V,
  Tj = -40 to 125°C

Note: The 176-pin HLFQFP does not have pins AVCC1, AVSS1, VREFH1, and VREFL1.

Table 47.2 DC Characteristics (1)

Item	Symbol	min	typ	max	Unit	Test Conditions
Power supply voltage (I/O)	VCCQ33	3.0	3.3	3.6	V

				253	730	mA	Tj = -40 to 125 °C (R7S910015CBG, R7S910115CBG)
				245	718	mA	Tj = -40 to 125 °C (R7S910026CBG, R7S910126CBG)
				238	709	mA	Tj = -40 to 125 °C (R7S910011CBG, R7S910111CBG)
				189	651	mA	Tj = -40 to 125 °C (R7S910025CBG, R7S910125CBG)
				181	641	mA	Tj = -40 to 125 °C (R7S910002CBG, R7S910006CBG, R7S910102CBG, R7S910106CBG)
				180	640	mA	Tj = -40 to 125 °C (R7S910001CFP, R7S910101CFP)
		300MHz		225	696	mA	Tj = -40 to 125 °C (R7S910036CBG, R7S910136CBG)
				169	629	mA	Tj = -40 to 125 °C (R7S910035CBG, R7S910135CBG)
	PLLVDD0 + PLLVDD1		PLLIcc	3.2	5	mA	
	VCCQ33		V33Icc	19*1, *2	—	mA	
	AVCC0		AV0Icc	2	5	mA	A/D conversion (unit 0)
	AVCC1		AV1Icc	0.7	1.5	mA	A/D conversion (unit 1)

Table 47.3 DC Characteristics (2) [Power Supply] (2 / 2)

Item	Type	Symbol	typ	max	Unit	Test Conditions
Normal operation	VREFH0	VRF0Icc	0.07	0.2	mA	A/D conversion (unit 0)
	VREFH1	VRF1Icc	0.07	0.2	mA	A/D conversion (unit 1)
	DVDD_USB	V12UIcc	5.1	9	mA	USB high-speed communication
			3.5	9	mA	USB full-speed communication
	VDD33_USB	V33UIcc	15*1	—	mA	USB high-speed communication
			10*1	—	mA	USB full-speed communication
Standby mode with all modules being inactive (reference value)	VDD	VIcc	41	—	mA	
	PLLVDD0 + PLLVDD1	PLLIcc	3.2	—	mA	
	VCCQ33	V33Icc	0.35*1, *2	—	mA	
	AVCC0	AV0Icc	0.64	—	µA	
	AVCC1	AV1Icc	0.32	—	µA	
	VREFH0	VRF0Icc	0.24	—	µA	
	VREFH1	VRF1Icc	0.24	—	µA	
	DVDD_USB	V12UIcc	3.5	—	mA	UTMI suspend mode
	VDD33_USB	V33UIcc	9.6*1	—	mA	UTMI suspend mode

Note 1. These values are reference values. The actual operating current greatly depends on the system (such as unsharpened waveforms due to I/O load and toggle frequency). Be sure to measure these current values in the system.

Note 2. V33Icc must be 80 mA or less. (ΣI_{OH} in Table 47.9)

Table 47.4 DC Characteristics (3) [Except for USB2.0 Host/Function-Related Pins]

Item		Symbol	min	typ	max	Unit	Test Conditions
Schmitt trigger Input voltage	Other than 5-V tolerant pins	V_{IH1}	2.4	—	VCCQ33 + 0.3	V	
		V_{IL1}	–0.3	—	0.8	V	
		ΔV_{T1}	VCCQ33 × 0.05	—	—	V	
	5-V tolerant pins*1	V_{IH2}	VCCQ33 × 0.7	—	5.3*2	V	
		V_{IL2}	–0.3	—	VCCQ33 × 0.3	V	
		ΔV_{T2}	VCCQ33 × 0.05	—	—	V	
Input high level voltage (except for schmitt trigger input pins)		V_{IH3}	2.4	—	VCCQ33 + 0.3	V	
Input low level voltage (except for schmitt trigger input pins)		V_{IL3}	–0.3	—	0.8	V	
Output high level voltage	Other than 5-V tolerant pins	V_{OH}	VCCQ33 – 0.5	—	—	V	I_{OH} = -2 mA
Output low level voltage	Other than 5-V tolerant pins	V_{OL1}	—	—	0.4	V	I_{OL1} = 2 mA
	5-V tolerant pins*1	V_{OL2}	—	—	0.4	V	I_{OL2} = 3 mA
			—	—	0.6	V	I_{OL2} = 6 mA
Input leakage current		$\lvert I_{in} \rvert$	—	—	1.0	µA	$V_{in1} = V_{in2}$ = 0 V $V_{in1} = V_{in2}$ = VCCQ33
Three-state leakage current (off state)	Input/output and output pins excluding 5-V tolerant pins	$\lvert I_{TSI} \rvert$	—	—	1.0	µA	V_{in1} = 0 V V_{in1} = VCCQ33
	5-V tolerant pins*1		—	—	5.0	µA	V_{in2} = 0 V V_{in2} = VCCQ33
Input pull-up MOS current and resistance	Ports P50 to P56, P86 to P87, P90 to P97, PD0 to PD7	I_{pu1}	–300	—	–30	µA	VCCQ33 = 3.0 to 3.6 V $V_{in1} = V_{in2}$ = 0 V
		R_{pu1}	10	—	120	kΩ	
	Pins other than the above*3	I_{pu2}	–120	—	–7	µA	VCCQ33 = 3.0 to 3.6 V $V_{in1} = V_{in2}$ = 0 V
		R_{pu2}	25	—	515	kΩ	
Input pull-down MOS current and resistance	Ports P50 to P56, P86 to P87, P90 to P97, PD0 to PD7	I_{pd1}	30	—	300	µA	VCCQ33 = 3.0 to 3.6 V $V_{in1} = V_{in2}$ = VCCQ33
		R_{pd1}	10	—	120	kΩ	
	Pins other than the above*3	I_{pd2}	7	—	120	µA	VCCQ33 = 3.0 to 3.6 V $V_{in1} = V_{in2}$ = VCCQ33
		R_{pd2}	25	—	515	kΩ	
Pin capacity	All input/output and input pins	C_{in}	—	—	10	pF	

Note 1. Ports PC0 to PC7 and P30 are 5-V tolerant.
Note 2. When VCCQ33 is less than 3.00 V, do not apply voltage of 3.6 V or higher to 5-V tolerant pins.
Note 3. 5-V tolerant pins are not included.

Table 47.5 DC Characteristics (4) [USB2.0 USB_RREF Pin]

Item	Symbol	min	typ	max	Unit	Test Conditions
Reference resistor	R_{REF}	200 ±1%			Ω	

Table 47.6 DC Characteristics (5) [USB2.0 Host/Function-Related Pins (Items for Both Full Speed and High Speed)*1]

Item	Symbol	min	typ	max	Unit	Test Conditions
DP pull-up resistor (when the function controller operation is selected)	R_{PU}	0.900	—	1.575	kΩ	Idle
		1.425	—	3.090	kΩ	Transmission/ reception
DP/DM pull-down resistors (when the host function is selected)	R_{PD}	14.25	—	24.80	kΩ	

Note 1. USB_DP and USB_DM pins

Table 47.7 DC Characteristics (6) [USB2.0 Host/Function-Related Pins (Full Speed)*1]

Item	Symbol	min	typ	max	Unit	Measuring Condition
Input high level voltage	V_{FSIH}	2.0	—	—	V	
Input low level voltage	V_{FSIL}	—	—	0.8	V	
Differential input sensitivity	V_{FSDI}	0.2	—	—	V	| (USB_DP) – (USB_DM) |
Differential common mode range	V_{FSCM}	0.8	—	2.5	V	
Output high level voltage	V_{FSOH}	2.8	—	3.6	V	I_{FSOH} = -200 µA
Output low level voltage	V_{FSOL}	0.0	—	0.3	V	I_{FSOL} = 2 mA
Output signal crossover voltage	V_{FSCRS}	1.3	—	2.0	V	CL = 50 pF (full-speed)

Note 1. USB_DP and USB_DM pins

Table 47.8 DC Characteristics (7) [USB2.0 Host/Function-Related Pins (High Speed)*1]

Item	Symbol	min	typ	max	Unit	Test Conditions
Squelch detection threshold voltage (differential voltage)	V_{HSSQ}	100	—	150	mV	
Common mode voltage range	V_{HSCM}	-50	—	500	mV	
Idle state	V_{HSOI}	-10.0	—	10.0	mV	
Output high level voltage	V_{HSOH}	360	—	440	mV	
Output low level voltage	V_{HSOL}	-10.0	—	10.0	mV	
Chirp J output voltage (differential)	V_{CHIRPJ}	700	—	1100	mV	
Chirp K output voltage (differential)	V_{CHIRPK}	-900	—	-500	mV	

Note 1. USB_DP and USB_DM pins

Table 47.9 Permissible Output Currents

Item		Symbol	min	typ	max	Unit
Permissible output low current (average value per pin)	Other than 5-V tolerant pins	I_{OL1}	—	—	2.0	mA
	5-V tolerant pins	I_{OL2}	—	—	3.0	mA
Permissible output low current (maximum value per pin)	Other than 5-V tolerant pins	I_{OL1}	—	—	4.0	mA
	5-V tolerant pins	I_{OL2}	—	—	6.0	mA
Permissible output low current (total)	Total of all output pins	ΣI_{OL}	—	—	80	mA
Permissible output high current (average value per pin)	All output pins	I_{OH}	—	—	-2.0	mA
Permissible output high current (maximum value per pin)	All output pins	I_{OH}	—	—	-4.0	mA
Permissible output high current (total)	Total of all output pins	ΣI_{OH}	—	—	-80	mA

[Usage Note] All output current values shall be within the values in Table 47.9 to ensure the reliability of this LSI.

47.4 AC Characteristics

- Conditions: VDD = PLLVDD0 = PLLVDD1 = DVDD_USB = 1.14 to 1.26 V,
  VCCQ33 = AVCC0 = AVCC1 = VREFH0 = VREFH1 = VDD33_USB = 3.0 to 3.6 V
  VSS = PLLVSS0 = PLLVSS1 = AVSS0 = AVSS1 = VREFL0 = VREFL1 = VSS_USB = 0 V,
  Tj = -40 to 125°C

Note: The 176-pin HLFQFP does not have pins AVCC1, AVSS1, VREFH1, and VREFL1.

Table 47.10 Operating Frequency

Item			Symbol	min	max	Unit
Operating frequency	CPU clock (CPUCLK)	*1	f	150	600	MHz
		*2		150	450	
		*3		150	300	
	System clock (ICLK)			150		
	Peripheral module clock (PCLKA)			150		
	Peripheral module clock (PCLKB)			75		
	Peripheral module clock (PCLKC)			150		
	Peripheral module clock (PCLKD)			75		
	Peripheral module clock (PCLKE)			18.75	75	
	Peripheral module clock (PCLKF)			7.5	60	
	Peripheral module clock (PCLKG)			7.5	60	
	Peripheral module clock (PCLKH)			60		
	High-speed serial clock (SERICLK)			120	150	
	ΔΣ interface clock output (DSCLK0, DSCLK1)			6.25	25	
	External bus clock output (CKIO)			18.75	75	
	External clock output for Ethernet PHY (CLKOUT25M)			25	50	

Note 1. For R7S910007CBG, R7S910107CBG, R7S910013CBG, R7S910113CBG, R7S910017CBG, R7S910117CBG, R7S910018CBG, R7S910118CBG, R7S910027CBG, R7S910127CBG, R7S910028CBG, and R7S910128CBG only.
Note 2. For R7S910001CFP, R7S910101CFP, R7S910002CBG, R7S910102CBG, R7S910006CBG, R7S910106CBG, R7S910011CBG, R7S910111CBG, R7S910015CBG, R7S910115CBG, R7S910016CBG, R7S910116CBG, R7S910025CBG, R7S910125CBG, R7S910026CBG, and R7S910126CBG only.
Note 3. For R7S910035CBG, R7S910135CBG, R7S910036CBG, and R7S910136CBG only.

47.4.1 Clock Timing

Table 47.11 CKIO Pin Output Timing

Output load condition: C = 30 pF

Item	Symbol	min	typ	max	Unit	Test Conditions
CKIO pin output cycle time	t_{CKcyc}	13.3	—	53.4	ns	Figure 47.2
CKIO pin output high level pulse width	t_{CKH}	$t_{CKcyc}/2 - t_{CKr}$	—	—	ns	
CKIO pin output low level pulse width	t_{CKL}	$t_{CKcyc}/2 - t_{CKf}$	—	—	ns	
CKIO pin output rising time 1	t_{CKr}	—	—	5	ns	CKIO: High drive output setting*1 V_{OH} = VCCQ33 – 0.5 V V_{OL1} = 0.4 V
CKIO pin output falling time 1	t_{CKf}	—	—	5	ns	
CKIO pin output rising time 2	t_{CKr}	—	—	9	ns	CKIO: Normal output setting V_{OH} = VCCQ33 – 0.5 V V_{OL1} = 0.4 V
CKIO pin output falling time 2	t_{CKf}	—	—	9	ns	
CKIO pin output rising time 3	t_{CKr}	—	—	2.5	ns	CKIO: High drive output setting*1 V_{OH} = 2.0 V V_{OL1} = 0.8 V
CKIO pin output falling time 3	t_{CKf}	—	—	2.5	ns	
CKIO pin output rising time 4	t_{CKr}	—	—	4.5	ns	CKIO: Normal output setting V_{OH} = 2.0 V V_{OL1} = 0.8 V
CKIO pin output falling time 4	t_{CKf}	—	—	4.5	ns	

Note 1. When connecting SDRAM, be sure to set the B0 bit in the drive capacity control register (DSCR) to 1 to be a high drive output.

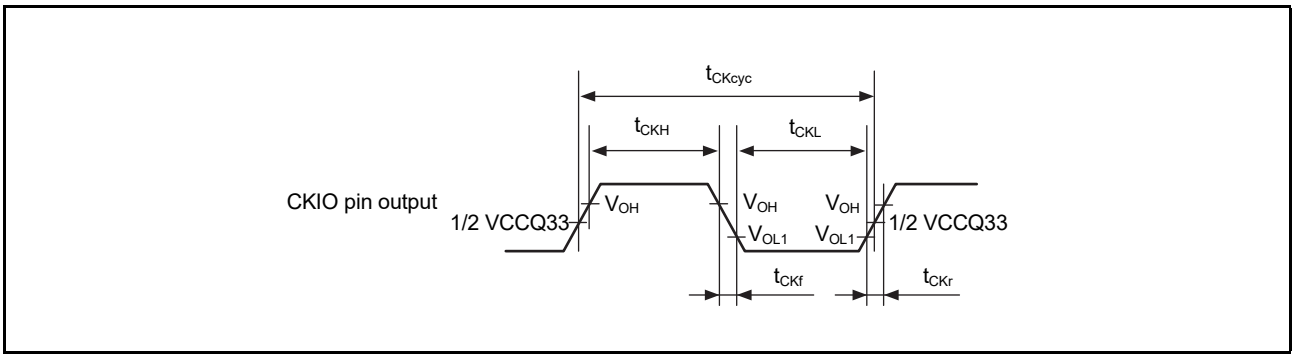

Figure 47.2 CKIO Pin Output Timing

Table 47.12 CLKOUT25Mn Timing

Output load conditions: V_{OH} = 2.0 V, V_{OL1} = 0.8 Vn, C = 25 pF (RMII)
V_{OH} = VCCQ33 – 0.5 V, V_{OL1} = 0.4 V, C = 30 pF (MII)

Item		Symbol	min	max	Unit	Test Conditions
CLKOUT25Mn (RMII)	CLKOUT25Mn cycle time	T_{ck1}	20	—	ns	Figure 47.3
	CLKOUT25Mn frequency Typ. 50 MHz	—	50 ± 50 ppm		MHz	
	CLKOUT25Mn duty	—	35	65	%	
	CLKOUT25Mn output low pulse width 1	T_{ckl1}	$T_{ck1}/2 - T_{ckf1}$	$T_{ck1}/2 + T_{ckf1}$	ns	
	CLKOUT25Mn output high pulse width 1	T_{ckh1}	$T_{ck1}/2 - T_{ckr1}$	$T_{ck1}/2 + T_{ckr1}$	ns	
	CLKOUT25Mn rising/falling time 1	$T_{ckr1/ckf1}$	0.5	4	ns	
CLKOUT25Mn (MII)	CLKOUT25Mn cycle time	T_{ck2}	40	—	ns	Figure 47.4
	CLKOUT25Mn frequency Typ. 25 MHz	—	25 ± 50 ppm		MHz	
	CLKOUT25Mn duty	—	35	65	%	
	CLKOUT25Mn output low pulse width 2	T_{ckl2}	$T_{ck2}/2 - T_{ckf2}$	$T_{ck2}/2 + T_{ckf2}$	ns	
	CLKOUT25Mn output high pulse width 2	T_{ckh2}	$T_{ck2}/2 - T_{ckr2}$	$T_{ck2}/2 + T_{ckr2}$	ns	
	CLKOUT25Mn rising/falling time 2	$T_{ckr2/ckf2}$	0.5	9	ns	

n = 0 to 2

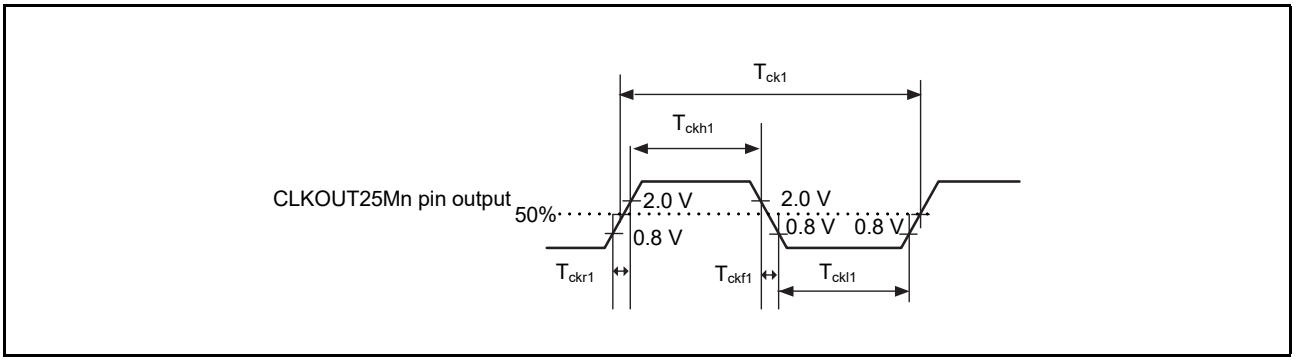

Figure 47.3 CLKOUT25Mn Pin Output Timing 1

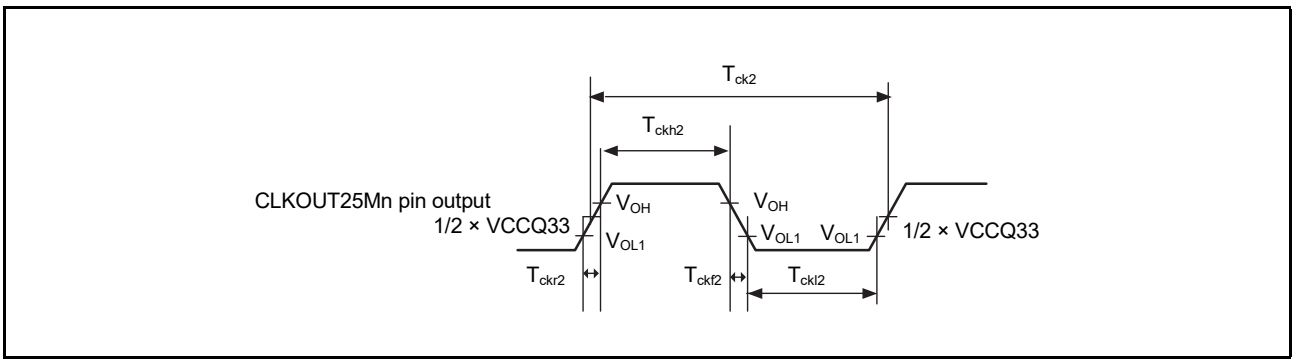

Figure 47.4 CLKOUT25Mn Pin Output Timing 2

Table 47.13 EXTAL Clock Timing

Item	Symbol	min	typ	max	Unit
EXTAL external clock input cycle time	t_{EXcyc}	40.00 ± 50 ppm			ns
		25.00 ± 25ppm*1			MHz

Note 1. When EtherCAT is in use.

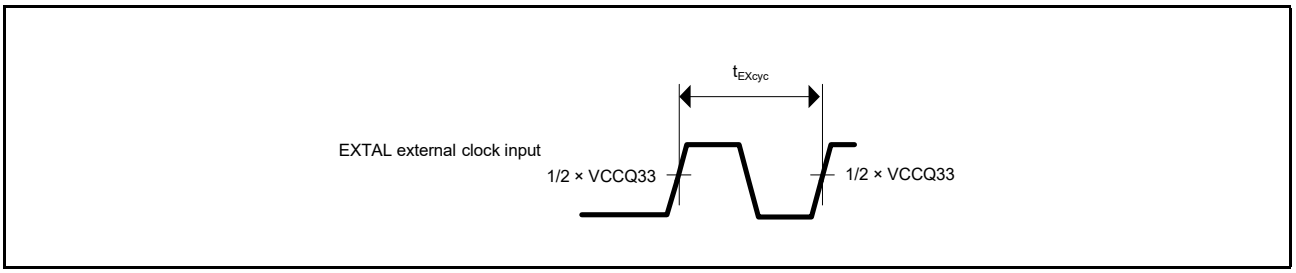

Figure 47.5 EXTAL External Clock Input Timing

Table 47.14 XTAL Clock Timing

Item	Symbol	min	typ	max	Unit
XTAL clock oscillator output cycle*1	$t_{XTALcyc}$		40.00 ± 50 ppm*2		ns

Note 1. When using the XTAL clock, ask the oscillator manufacturer to evaluate oscillation of the oscillator. For the oscillation stabilization time, see the evaluation result provided by the oscillator manufacturer.
Note 2. When using the EtherCAT, make sure that the clock timing satisfies 25.00 MHz ± 25 ppm.

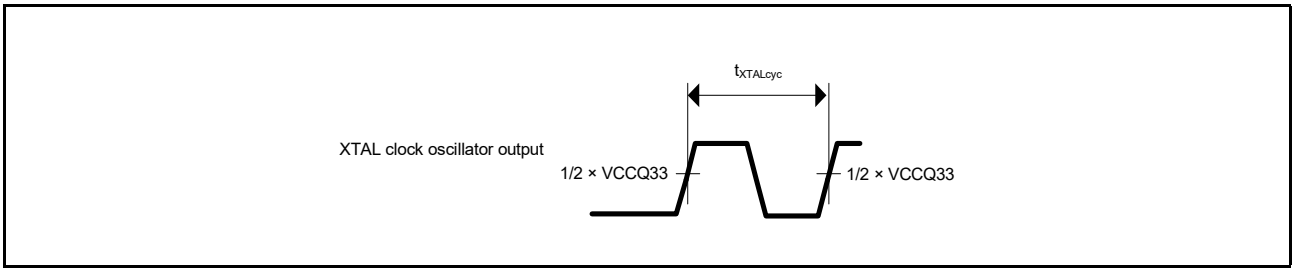

Figure 47.6 XTAL Clock Oscillator Output Timing

Table 47.15 LOCO Clock Timing

Item	Symbol	min	typ	max	Unit	Test Conditions
LOCO clock cycle time	t_{Lcyc}	4.62	4.17	3.79	µs	
LOCO clock oscillation frequency	f_{LOCO}	216	240	264	kHz	
LOCO clock oscillation stabilization wait time	t_{LOCOWT}	—	—	40	µs	Figure 47.7

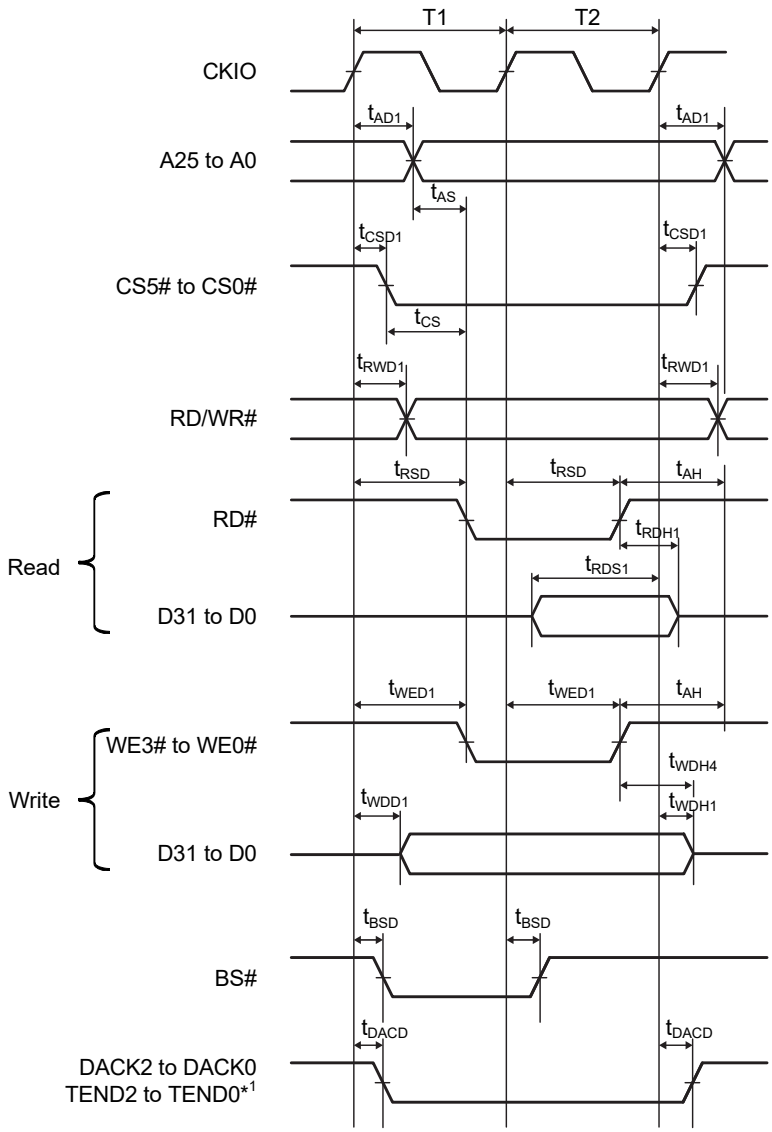
Multiplex address hold time		t_{MAH}	1	—	ns	Figure 47.16
Address setup time to AH#		t_{AVVH}	$1/2t_{CKcyc}$ – 2	—	ns	Figure 47.16
DACK/TEND delay time		t_{DACD}	See DMAC timing	See DMAC timing	ns	Figure 47.12 to Figure 47.33

Note 1. Take the number of cycles of waiting that suits the system configuration into consideration with regard to the fmax value for CKIO (the external bus clock). When CKIO is running at 50 MHz or a higher frequency, set the B0 bit of the driving ability control register (DSCR) to 1 to select high-drive output. When CKIO is running at less than 50 MHz, normal output of CKIO can be used (DSCR.B0 bit = 0).

Note 2. Notation of $1/2t_{CKcyc}$ in the delay time, setup time, and hold time shows 1/2 cycles from the clock rising edge, that is, the reference of clock falling.

Note 3. These are values when SDRAM (TYPE[2:0] bits = 100b) is selected in the CSn space bus control register (CSnBCR) and high-drive output (B0 bit = 1) is selected in the driving ability control register (DSCR) for CKIO.

Note 4. These are values when high-drive output (B0 bit = 1) and normal output (B0 bit = 0) are respectively selected in the driving ability control register (DSCR) for CKIO.



Note 1. DACKn and TENDn are waveforms when “active low” is specified.

47.6 A/D Conversion Characteristics

- Conditions: VDD = PLLVDD0 = PLLVDD1 = DVDD_USB = 1.14 to 1.26 V,
  VCCQ33 = AVCC0 = AVCC1 = VREFH0 = VREFH1 = VDD33_USB = 3.0 to 3.6 V
  VSS = PLLVSS0 = PLLVSS1 = AVSS0 = AVSS1 = VREFL0 = VREFL1 = VSS_USB = 0 V,
  Tj = -40 to 125°C

Note: The 176-pin HLFQFP does not have pins AVCC1, AVSS1, VREFH1, and VREFL1.

Table 47.37 12-Bit A/D (Unit 0) Conversion Characteristics

Item		min	typ	max	Unit	Test Conditions
Resolution		8	—	12	Bit	
Analog input capacitance		—	—	30	pF	
Channel-dedicated sample-and-hold circuits in use (AN000 to AN003) When disconnection detection assistance is in use	Conversion time*1 (Operation at PCLKF = 60 MHz) Permissible signal source impedance Max. = 1.0 kΩ	1.2 (0.4 + 0.4) *2	—	3.6	µs	• Sampling of channel-dedicated sample-and-hold circuits in 24 states • Sampling in 24 states
	Offset error	—	—	±7.5	LSB	
	Full-scale error	—	—	±7.5	LSB	
	Quantization error	—	±0.5	—	LSB	
	Absolute accuracy	—	—	±7.5	LSB	
	DNL differential nonlinearity error	—	—	±3.0	LSB	
	INL integral nonlinearity error	—	—	±4.0	LSB	
	Holding characteristics of sample-and-hold circuits	—	—	3.2	µs	Self-diagnosis + 4-channel simultaneous sampling
	Dynamic range	0.25	—	VREFH0 – 0.25	V	
Channel-dedicated sample-and-hold circuits in use (AN000 to AN003) When disconnection detection assistance is not in use	Conversion time*1 (Operation at PCLKF = 60 MHz) Permissible signal source impedance Max. = 1.0 kΩ	1.2 (0.4 + 0.4) *2	—	3.6	µs	• Sampling of channel-dedicated sample-and-hold circuits in 24 states • Sampling in 24 states
	Offset error	—	—	±6.5	LSB	
	Full-scale error	—	—	±6.5	LSB	
	Quantization error	—	±0.5	—	LSB	
	Absolute accuracy	—	—	±6.5	LSB	
	DNL differential nonlinearity error	—	—	±3.0	LSB	
	INL integral nonlinearity error	—	—	±4.0	LSB	
	Holding characteristics of sample-and-hold circuits	—	—	3.2	µs	Self-diagnosis + 4-channel simultaneous sampling
	Dynamic range	0.25	—	VREFH0 – 0.25	V	
Channel-dedicated sample-and-hold circuits not in use (AN000 to AN007)	Conversion time*1 (Operation at PCLKF = 60 MHz) Permissible signal source impedance Max. = 1.0 kΩ	0.483 (0.267)*2	—	—	µs	Sampling in 16 states
	Offset error	—	—	±5.0	LSB	
	Full-scale error	—	—	±5.0	LSB	
	Quantization error	—	±0.5	—	LSB	
	Absolute accuracy	—	—	±6.0	LSB	
	DNL differential nonlinearity error	—	—	±2.5	LSB	
	INL integral nonlinearity error	—	—	±3.0	LSB	

Note: The above specified values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.
Note 1. The conversion time is the total of the sampling time and the comparison time (t_{SPLSH} + t_{CONV} in Figure 43.31 and Figure 43.32 in section 43, 12-Bit A/D Converter (S12ADCa)). The number of sampling states is indicated for each item in Test Conditions.
Note 2. The value in parentheses indicates the sampling time.

Table 47.38 12-Bit A/D (Unit 1) Conversion Characteristics

Item		min	typ	max	Unit	Test Conditions
Resolution		8	—	12	Bit	
Conversion time*1 (Operation at PCLKF = 60 MHz)	Permissible signal source impedance Max. = 1.0 kΩ	0.883 (0.667)*2	—	—	µs	Sampling in 40 states
Analog input capacitance		—	—	30	pF	
Offset error		—	—	±6.0	LSB	
Full-scale error		—	—	±6.0	LSB	
Quantization error		—	±0.5	—	LSB	
Absolute accuracy		—	—	±6.0	LSB	
DNL differential nonlinearity error		—	—	±3.0	LSB	
INL integral nonlinearity error		—	—	±4.0	LSB	

Note: The above specified values apply when there is no access to the external bus during A/D conversion. If access proceeds during A/D conversion, values may not fall within the above ranges.
Note 1. The conversion time is the total of the sampling time and the comparison time (t_{SPLSH} + t_{CONV} in Figure 43.31 and Figure 43.32 in section 43, 12-Bit A/D Converter (S12ADCa)). The number of sampling states is indicated for each item in Test Conditions.
Note 2. The value in parentheses indicates the sampling time.

47.7 Temperature Sensor Characteristics

- Conditions: VDD = PLLVDD0 = PLLVDD1 = DVDD_USB = 1.14 to 1.26 V,
  VCCQ33 = AVCC0 = AVCC1 = VREFH0 = VREFH1 = VDD33_USB = 3.0 to 3.6 V
  VSS = PLLVSS0 = PLLVSS1 = AVSS0 = AVSS1 = VREFL0 = VREFL1 = VSS_USB = 0 V,
  Tj = -40 to 125°C

Note: The 176-pin HLFQFP does not have pins AVCC1, AVSS1, VREFH1, and VREFL1.

Table 47.39 Temperature Sensor Characteristics

Item	min	typ	max	Unit	Test Conditions
Relative accuracy	—	±1	—	°C	
Temperature slope	—	4.1	—	mV/°C	
Output voltage (at 25°C)	—	1.21	—	V	
Temperature sensor start time	—	—	30	µs	
Sampling time	4.25	—	—	µs	ADSSTRT.SST[7:0] = 255 states (when PCLKF [ADC (unit0) sampling CLK] = 60 MHz)

47.8 Oscillation Stop Detection Timing

Table 47.40 Oscillation Stop Detection Circuit Characteristics

Item	Symbol	min	typ	max	Unit	Test Conditions
Clock switching time	t_{dr}	—	—	1	ms	Figure 47.86

REVISION HISTORY — RZ/T1 Group User's Manual: Hardware

Rev.	Date	Description	
		Page	Summary
0.60	Nov. 14, 2014	—	First edition, issued
0.70	Dec. 25, 2014	Features	
		53	■ Operating temperature range: Heading title and description corrected
		Section 1 Overview	
		63	Table 1.3 List of Products (2 / 2): Note corrected
		73	Figure 1.3 Pin Arrangement (176-pin HLQFP): The names of pins 33, 34, 38, 39, and 91, corrected
		78	Table 1.5 Pin Assignments (320-Pin FBGA) (5 / 8): The names of pins M20 and P19, corrected
		79	Table 1.5 Pin Assignments (320-Pin FBGA) (6 / 8): The names of pins R14, R19, R20, T9, V7, and V8, corrected
		81	Table 1.5 Pin Assignments (320-Pin FBGA) (8 / 8): The names of pins Y16 and Y17, corrected
		82	Table 1.6 Pin Assignments (176-Pin HLQFP) (1 / 4): The names of pins 33, 34, 38, and 39, corrected
		83	Table 1.6 Pin Assignments (176-Pin HLQFP) (2 / 4): The names of pins 58, 59, 60, 79, 82, and 83, corrected
		84	Table 1.6 Pin Assignments (176-Pin HLQFP) (3 / 4): The names of pins 91 and 110, corrected
		85	Table 1.6 Pin Assignments (176-Pin HLQFP) (4 / 4): The names of pins 136, 153, 154, 155, 156, and 157, corrected
		91	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (6 / 10): The name of pin M20, corrected
		92	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (7 / 10): The names of pins P19, R8, and R14, corrected
		93	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (8 / 10): The names of pins R19, R20, T9, V7, and V8, corrected
		94	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (9 / 10): The names of pins Y16 and Y17, corrected
		Section 4 Address Space	
		122	4.1 Address Space: Description corrected
		123	Figure 4.1 Memory Map: The description of the figure and Note 1, corrected
		Section 5 I/O Registers	
		199	Table 5.1 List of I/O Registers (Address Order) (73 / 86): The addresses and module symbols of ADCMPANSER and ADCMPLER, corrected. The ADCMPANSER and ADCMPLER lines, moved next to the ADCMPCR line.
		Section 7 Clock Generation Circuit	
		220	Table 7.1 Specifications of Clock Generation Circuit: Description of Frequency multiplication ratio at PLL0 circuit, corrected
		221	Table 7.2 Specifications of Clock Generation Circuit (Internal Clock) (1 / 2): The frequency of USB clock M (USBMCLK), corrected
		226, 227	7.2.1 System Clock Control Register (SCKCR): In the bit chart and the table of bits, bit 17 corrected to reserved
		Section 10 Debugging Interface	
		264	Figure 10.1 CoreSight Configuration Diagram, corrected

Rev.	Date	Description	
		Page	Summary
0.70	Dec. 25, 2014	265	Figure 10.2 CoreSight Configuration Diagram (in Products Incorporating an R-IN Engine), corrected
		Section 12 Interrupt Controller (ICUA)	
		286	12.2.4 Non-maskable Interrupt Status Register (NMISR): In the bit chart, the name of bit 0 corrected
		355	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table (2 / 9): The source of vector number 63, corrected
		358	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table (5 / 9): The source of vector number 169, corrected
		361	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table (8 / 9): Vector Number 253 corrected to reserved
		Section 14 Bus State Controller	
		410	14.4.4 Refresh Timer Control/Status Register (RTCSR): In the table of bits, the symbol of bit 7 corrected
		Section 15 DMA Controller (DMACAa)	
		475	Table 15.1 Specifications of DMAC: Description of Interrupt request, corrected
		507	15.3.22 Descriptor Interval Register n (DSCITVL_X (X = A or B)): Functional description of the DITVL bit, corrected
		532	15.4.3.2 Round-Robin Mode: Description corrected
		534	Table 15.20 Method of Detecting DMA Transfer Request Signals: Description of Edge detection, corrected
		564	Table 15.29 DMA Transfer Setting Example 4 (Descriptor 1): Table header corrected (Item → Description)
		565	Table 15.30 DMA Transfer Setting Example 4 (Descriptor 2): Data size, corrected (64 bits → 256 bits)
		566	Table 15.32 Descriptor Settings: Descriptor 1, Descriptor 2, and Descriptor 3 of CFG (Configuration) corrected
		Section 17 I/O Ports	
		609	17.3.1 Port Direction Register (PDR): The erroneous description on the address, corrected
		Section 19 Multi-Function Timer Pulse Unit (MTU3a)	
		693	Table 19.6 TPSC[2:0] and TPSC2[2:0] (MTU0), corrected
		871	Table 19.78 MTU Interrupt Sources: TCIV4 and TCIV7 interrupt sources, corrected
		Section 20. Port Output Enable 3 (POE3)	
		959	20.2.20 MTU3 Pin Select Register (M3SELR): In the table of bits, the names of bits M3BSEL[3:0] and M3DSEL[3:0], corrected
		960	20.2.21 MTU4 Pin Select Register 1 (M4SELR1): In the table of bits, the names of bits M4ASEL[3:0] and M4CSEL[3:0], corrected
		961	20.2.22 MTU4 Pin Select Register 2 (M4SELR2): In the table of bits, the names of bits M4BSEL[3:0] and M4DSEL[3:0], corrected
		Section 22 16-Bit Timer Pulse Unit (TPUa)	
		1113	22.2.2 Timer Mode Register (TMDR): Note 3 and Note 4 corrected
		1153	Table 22.25 PWM Output Registers and Output Pins Register: Description in the Register column, corrected

Rev.	Date	Description	
		Page	Summary
0.70	Dec. 25, 2014	Section 28 Ethernet MAC (ETHERC)	
		1310	Table 28.3 MAC Function Selection Method (for Products Incorporating an R-IN Engine): Media I/F Port 2 at MAC[2:0] = 001 or 101, corrected
		1310	Table 28.4 MAC Function Selection Method: Media I/F Port 1 at MAC[2:0] = 011, corrected
		1331	28.2.2.17 LPI CLIENT Timing Control Register (GMAC_LPI_TIMING): In the bit chart, the value after reset for bits 13, 11, 6, 5, 3, and 2, corrected
		Section 29 Ethernet Switch	
		1354	29.2.1.3 Ethernet Switch Operating Mode Setting Register (ETHSWMD): Note deleted. In the bit chart, bits 2 and 0 corrected to reserved
		1395	29.2.5.8 Generate Timer Periodic Event Register (ATIME_EVT_PERIOD): In the bit chart, the value after reset for bits 29, 28, 27, 25, 24, 23, 20, 19, 17, 15, 14, 11, and 9, corrected
		Section 30 EtherCAT Slave Controller (Only for Products Incorporating an R-IN Engine)	
		1464	30.4.2 Revision Register (REVISION): In the bit chart, the value after reset for bits 1 and 0, corrected
		Section 31 USB2.0HS Host Module (USBh)	
		1637	31.5.1 Externally Supplied Clocks: Description corrected
		1638	Figure 31.6 Clock Distribution Diagram, corrected (HOST clock, HCLK_ROOT, PHYDCLK48, and PHYDCLK60, deleted)
		1642	31.6.3 Time Required to Clear Interrupt Signals, (1) Host Logic: Description corrected
		Section 33 Serial Communications Interface with FIFO (SCIFA)	
		1766	33.3.10 FIFO Control Register (FCR): register contents table, Functional description of RFRST and TFRST, corrected
		Section 34 I^2C Bus Interface (RIIC)	
		1829	34.2.14 I^2C Bus Bit Rate High-Level Register (ICBRH): Note 1 corrected
		1830	Table 34.5 Examples of ICBRH/ICBRL Settings for Transfer Rate: Contents of the table corrected. The erroneous description on the Note, corrected.
		Section 42 Error Control Module (ECM)	
		2250	Table 42.2 ECM Error Input (1 / 2): Module and Function for Error Source Numbers 1 to 3, corrected
		2254	42.2.3 ECM Master/Checker Error Source Status Register 0 (ECMmESSTR0 (m = M or C)): Functional description of ECMmSSE000, ECMmSSE001, and ECMmSSE002 corrected
		2285	42.2.23 ECM Protection Command Register (ECMPCMD1): The table of bits, corrected (Symbol, Bit Name, and Description of bits 7 to 0 and bits 31 to 8, exchanged)
		2308	42.3.4.1 Protection Unlock Sequence: The description of procedure 3, corrected
		Section 43 12-Bit A/D Converter (S12ADCa)	
		2348	43.2.18 A/D Compare Channel Select Extended Register (ADCMPANSER): Address corrected
		2350	43.2.20 A/D Compare Level Extended Register (ADCMPLER): Address corrected
		Section 46 RAM (Product Option)	
		2427	Table 46.1 Specifications of RAM: The description of the “Item” column, corrected
		2428	46.2.1 Protect Command Register (RAMPCMD): Address corrected
		2430	46.2.3 ECC Decoder Configuration Register (RAMEDC) (for Products Incorporating an R-IN Engine): Address corrected
		2433	46.2.5 ECC Encoder Configuration Register (RAMEEC) (for Products Incorporating an R-IN Engine): Address corrected

Rev.	Date	Description	
		Page	Summary
0.70	Dec. 25, 2014	2437	46.2.7 2-Bit ECC Error Status Register (RAMDBEST) (for Products Incorporating an RIN Engine): Address corrected
		2439	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine): Address corrected
		2440	46.2.10 2-Bit ECC Error Counter Register (RAMDBECNT): Address corrected
		2441 to 2443	46.3 Description of Operation, added
		Section 47 Electrical Characteristics (Target)	
		2444	Table 47.1 Absolute Maximum Rating Conditions: VSS = PLLVSS0 = PLLVSS1 = AVSS0 = AVSS1 = VREFL0 = VREFL1 = VSS_USB = 0 V, corrected (Operating temperature (Junction temperature))
		2504	Table 47.32 ETHERC Timing Output load conditions: VOH = 2.0 V, VOL1 = 0.8 V, C = 25 pF (RMII), VOH = VCCQ33 × 0.5, VOL1 = VCCQ33 × 0.5, C = 30 pF (MII), corrected. The lines of ETHn_CRS setup time, ETHn_CRS hold time, ETHn_COL setup time, and ETHn_COL hold time, deleted.
		2506	Figure 47.72 MII Transmission Timing (Normal Operation), corrected (t_{CRSc} and t_{CRSh} deleted)
		2506	Figure 47.73 MII Transmission Timing (Conflict Occurrence), corrected (t_{COLs} and t_{COLh} deleted)
0.80	Apr. 21, 2015	All	Module name modified: ICU-M → ICUMB
		All	Configuration of the input/output pins unified
		Section 1 Overview	
		66 to 72	1.4 Pin Functions, pin name: PHYLINK2, deleted
		74	Figure 1.3 Pin Arrangement (176-pin HLQFP), pin name: ERROROUT corrected to ERROROUT#
		75 to 82	Table 1.5 Pin Assignments (320-Pin FBGA), pin names changed (MOSIn_BLUE → MOSIn, MOSIn_RED → MOSIn)
		77	Table 1.5 Pin Assignments (320-Pin FBGA), pin number H5: pin name ERROROUT corrected to ERROROUT#
		77	Table 1.5 Pin Assignments (320-Pin FBGA), pin number H18: pin name MDAT2 added
		80	Table 1.5 Pin Assignments (320-Pin FBGA), pin number R8: pin names WE0# and DQMLL deleted
		80	Table 1.5 Pin Assignments (320-Pin FBGA), pin number T8: pin name A1 deleted
		83 to 86	Table 1.6 Pin Assignments (176-Pin HLQFP), pin names changed (MOSIn_BLUE → MOSIn, MOSIn_RED → MOSIn)
		83	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 1: pin name CATI2CCLK deleted
		83	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 7: pin name ERROROUT corrected to ERROROUT#
		84	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 56: pin names WE0# and DQMLL deleted
		84	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 57, pin name A1 deleted
		84	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 89: pin name ADTRG1 deleted
		85	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 121, pin name MDAT2 added
		86	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 168: pin names CATSYNC1 and CATLATCH1 deleted
		86	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 171: pin names CATSYNC0 and CATLATCH0 deleted
		86	Table 1.6 Pin Assignments (176-Pin HLQFP), pin number 176, pin name CATI2CDATA deleted
		87 to 96	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), pin names changed (MOSIn_BLUE → MOSIn, MOSIn_RED → MOSIn)
		87	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), pin number A12, Power Supply Clock System Control: VSS added
		90	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), pin number F7, Power Supply Clock System Control: VCCQ33 added

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	90	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), pin number H5, Power Supply Clock System Control: ERROROUT corrected to ERROROUT#
		94	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), pin number T2, Power Supply Clock System Control: VDD33_USB added
		97 to 102	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin names changed (MOSIn_BLUE → MOSIn, MOSIn_RED → MOSIn)
		97	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), ECATC deleted from the header of Communication
		97	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 1, CATI2CCLK in the Communication column deleted
		97	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 7, Power Supply Clock System Control: ERROROUT corrected to ERROROUT#
		98	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 56, WE0# and DQMLL in the Bus column deleted
		98	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 57, A1 in the Bus column deleted
		98	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 58, D1 in the Bus column deleted
		98	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 59, D2 in the Bus column deleted
		98	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 60, D3 in the Bus column deleted
		99	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 79, D4 in the Bus column deleted
		99	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 82, D5 in the Bus column deleted
		99	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 83, D6 in the Bus column deleted
		99	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 89, ADTRG1 in the S12ADC column deleted
		100	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 110, D7 in the Bus column deleted
		102	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 168, CATSYNC1 and CATLATCH1 in the Communication column deleted
		102	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 171, PHYRESETOUT#, CATSYNC0, and CATLATCH0 in the Communication column deleted
		102	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), pin number 176, CATI2CDATA in the Communication column deleted
		102	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP), Note 1 deleted
		Section 4 Address Space	
		124	Figure 4.1 Memory Map: Note 8. added to the peripheral I/O register (1 MB) of the Cortex-M3 (in products incorporating an R-IN Engine)
		124	Figure 4.1 Memory Map: Note 8. and Note 9. added
		125	Figure 4.2 Memory Map: Note 5. added
		126	Figure 4.3 Memory Map: Note 6. added
		Section 5 I/O Registers	
		127	(1) I/O register addresses (address order): Description on the number of access cycles, deleted
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0000h, Register Name: PCI Configuration Registers for OHCI Register Symbol: VID_DID was changed to VID_DID_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0000h, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: VID_DID was changed to VID_DID_A.

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0004h, Register Name, PCI Configuration Registers for OHCI Register Symbol: CMND_STS was changed to CMND_STS_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0004h, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: CMND_STS was changed to CMND_STS_A.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0008h, Register Name: PCI Configuration Registers for OHCI Register Symbol: REVID_CC was changed to REVID_CC_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0008h, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: REVID_CC was changed to REVID_CC_A.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 000Ch, Register Name: PCI Configuration Registers for OHCI Register Symbol: CLS_LT_HT_BIST was changed to CLS_LT_HT_BIST_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 000Ch, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: CLS_LT_HT_BIST was changed to CLS_LT_HT_BIST_A.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0010h, Register Name: PCI Configuration Registers for OHCI Register Symbol: BASEAD was changed to BASEAD_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0010h, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: BASEAD was changed to BASEAD_A.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 0018h, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: WIN2_BASEAD, deleted
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 002Ch, Register Name: PCI Configuration Registers for OHCI Register Symbol: SVID_SSID was changed to SVID_SSID_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 002Ch, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol: SVID_SSID was changed to SVID_SSID_A.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 003Ch, Register Name: PCI Configuration Registers for OHCI Register Symbol: INTR_LINE_PIN was changed to INTR_LINE_PIN_0.
		151	Table 5.1 List of I/O Registers (Address Order) Address: A005 003Ch, Register Name: PCI Configuration Registers for AHB-PCI Bridge Register Symbol, INTR_LINE_PIN was changed to INTR_LINE_PIN_A.
		152	Table 5.1 List of I/O Registers (Address Order) Address: A005 0804h, Register Name: PCIAHB_WIN2_CTR Register Symbol: PCIAHB_WIN2_CTR, deleted
		Section 6 Reset	
		217	6.2.2 Software Reset Register (SWRR1), bit chart: SWRR1 corrected
		218	6.2.3 Software Reset Register 2 (SWRR2) (for products incorporating an R-IN engine), bit chart: SWRR2 corrected
		Section 7 Clock Generation Circuit	
		229	7.2.2 System Clock Control Register 2 (SCKCR2): Value after reset of b4 in the bit chart, changed
		230	7.2.3 Delta-Sigma Interface Clock Control Register (DSCR): Value after reset of b16 and b4 in the bit chart, changed
		241	7.8.8 High-Speed Serial Clock (SERICLK): Description changed

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	Section 8 Clock Monitor Circuit (CLMA)	
		245	Table 8.1 Specifications of CLMAn (n = 2 to 0): Table title changed
		246	Figure 8.1 Block Diagram of CLMAn (n = 2 to 0): Description was added to the top of the figure.
		246	Figure 8.1 Block Diagram of CLMAn (n = 2 to 0): Figure title changed
		Section 9 Low-Power Consumption Function	
		257	9.2.2 Module Stop Control Register B (MSTPCRB): Bit name and functional description of b18 in table of bits, changed
		Section 10 Debugging Interface	
		264	10.1 Overview: Description changed
		264	Table 10.1 CoreSight Specifications: Table title changed
		265	Figure 10.1 Block Diagram of CoreSight: Figure title changed
		266	Figure 10.2 Block Diagram of CoreSight (for products incorporating an R-IN engine): Figure title changed
		269	Table 10.8 Configuration of Pins for the Debugging Interface: Description on the top was changed.
		269	Table 10.8 Configuration of Pins for the Debugging Interface: Table title changed
		270	10.2.1 Debugging Interface Control Register (DBGIFCNT) Symbol: SWVSEL was changed in the bit chart.
		276	10.3.5.2 Example Connection of the emulator That Can Drive the nTRST Output to High: Description changed
		276	Figure 10.8 Example of Connection Circuit of an emulator That Can Drive the nTRST Output to High: Figure number changed
		Section 12 Interrupt Controller (ICUA)	
		281	12.1 Overview: Description changed
		281	Table 12.1 Specifications of Interrupt Controller: Table title changed
		282	Figure 12.1 Block Diagram of Interrupt Controller: Figure title changed
		282	Figure 12.2 Block Diagram of Interrupt Controller (for products incorporating an R-IN engine): Figure title changed
		282	Figure 12.2 Block Diagram of Interrupt Controller (for products incorporating an R-IN engine): Interrupt sources, changed
		339	12.4.2.13 Interrupt Address Register (HVA0) Symbol: HVA in the bit chart, changed
		354	12.4.3.1 Interrupt Vector Table: Description changed
		354	12.4.3.1 Interrupt Vector Table, Cortex-R4F/DMAC interrupt vector table: Description of the detection type, changed
		355-364	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table: Note 3. added
		372	Figure 12.10 Concept of Multiple Interrupts (2/2): Note 1. changed to Note 2. in interrupt request u (level 2)
		376	12.5.2.1 Interrupt Vector Table for CM3: Description changed
		Section 13 Internal Buses	
		381	Table 13.1 Specifications of Internal Buses: Buses for Ethernet in the internal bus type column, changed
		381	Table 13.1 Specifications of Internal Buses: Note added
		382	Figure 13.1 Bus Configuration: “AHB2DMA” deleted
		382	Figure 13.1 Bus Configuration: “RAM1” changed to “RAM2”, “RAM2” changed to “RAM1”
		382	Figure 13.1 Bus Configuration: Note added to “RAM”1 and “RAM2”
		383	Figure 13.2 Bus Configuration (for products incorporating an R-IN engine): “AHB2DMA” deleted
		383	Figure 13.2 Bus Configuration (for products incorporating an R-IN engine): Note added to “I-RAM” and “D-RAM”

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	383	Figure 13.2 Bus Configuration (for products incorporating an R-IN engine): Note added to “I-RAM” and “D-RAM”
		Section14 Bus State Controller	
		385	Table 14.1 Bus State Controller Specifications, External WAIT pin corrected to External WAIT# pin
		386	Figure 14.1 Block Diagram of Bus State Controller, description above the figure corrected
		—	14.2 Input/Output Pins, deleted
		387	Table 14.2 Input/Output Pins of the Bus State Controller, title corrected
		400	14.4.2(1) • CS5WCR: CS5WCR bit table, functional description of b1, 0 and b12, 11, corrected
		420	Table 14.6 16-Bit External Device Access and Data Alignment in Little Endian, entries in the Operation column corrected
		430	14.4.5 MPX-I/O Interface, description corrected
		430	Figure 14.11 Access Timing for MPX Space (1) (Address Cycle No Wait, 1.5 Assertion Delay States, Data Cycle No Wait, 1.5 Delay States), title corrected
		431	Figure 14.12 Access Timing for MPX Space (2) (Address Cycle No Wait, 1.5 Assertion Delay States, Data Cycle No Wait, 1.5 Delay States), added
		432	Figure 14.13 MPX Access Timing for MPX Space (3) (Address Cycle Access Wait 1, Data Cycle No Wait), title corrected
		433	Figure 14.14 MPX Access Timing for MPX Space (4) (Address Cycle Access Wait 1, Data Cycle Wait 1, External Wait 1), title corrected
		450	14.5.6(4) Single Read, description corrected
		452	14.5.6(6) Single Write, description corrected
		476	Table 14.24 Number of Idle Cycles Inserted between Access Cycles to Different Memory Types, the number of cycles in the table corrected
		476	Table 14.24 Number of Idle Cycles Inserted between Access Cycles to Different Memory Types, Note 1 added
		Section 15 DMA Controller (DMACAa)	
		—	Heading title: 15.2 Input/Output Pins, deleted
		479	Table 15.2 Pin Configuration of the DMAC: Description was added to the top of the table.
		479	Table 15.2 Pin Configuration of the DMAC: Table title changed
		480	15.2.1 • For N0SA_n_N and N1SA_n_N (normal mode) Symbol: SA in the bit chart, changed
		481	15.2.1 • For N0SA_n_W and N1SA_n_W (write-only mode) Symbol: WD in the bit chart, changed
		482	15.2.2 Next Destination Address Register n (N0DA_n and N1DA_n) Symbol: DA in the bit chart, changed
		483	15.2.3 Next Transaction Byte Register n (N0TB_n and N1TB_n) Symbol: TB in the bit chart, changed
		484	15.2.4 Current Source Address Register (CRSA_n) Symbol: CRSA in the bit chart, changed
		485	15.2.5 Current Destination Address Register (CRDA_n) Symbol: CRDA in the bit chart, changed
		486	15.2.6 Current Transaction Byte Register (CRTB_n) Symbol: CRTB in the bit chart, changed
		494	15.2.11 Common Control Register (CMNCR): Value after reset of b3 in the bit chart, changed
		494	15.2.11 Common Control Register (CMNCR): Functional description of b3 in the bit chart, changed
		497	15.2.13 Channel Configuration Register n (CHCFG_n): Description changed
		501	15.2.15 Next Link Address Register n (NXLA_n) Symbol: NXLA in the bit chart, changed

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	502	15.2.16 Current Link Address Register n (CRLA_n) Symbol: CRLA in the bit chart, changed
		503	15.2.17 Source Continuous Register n (SCNT_n) Symbol: SCNT in the bit chart, changed
		504	15.2.18 Source Skip Register n (SSKP_n) Symbol: SSKP in the bit chart, changed
		506	15.2.19 Destination Continuous Register n (DCNT_n) Symbol: DCNT in the bit chart, changed
		507	15.2.20 Destination Skip Register n (DSKP_n) Symbol: DSKP in the bit chart, changed
		528	Figure 15.10 header Area: Description changed
		532	15.3.2.1 Single Transfer Mode: Description changed
		532	15.3.2.2 Block Transfer Mode: Description changed
		537	15.3.4 DMA Transfer Request: Description changed
		538 to 543	Table 15.21 DMA Transfer Request Detection Operation Setting Table: Note 2. added to the table heading, AM[2:0]
		538 to 543	Table 15.21 DMA Transfer Request Detection Operation Setting Table: DNA transfer source of DMA transfer request source: MTU3a, changed
		538 to 543	Table 15.21 DMA Transfer Request Detection Operation Setting Table: Note 3. added to CHCHG_n AM[2:0] of DMA transfer source: USB
		538 to 543	Table 15.21 DMA Transfer Request Detection Operation Setting Table: Note 2. and Note 3. added
		544	Figure 15.16 Edge Detection Timing (Rising Edge (HIEN = 1), DACK Output is Active during Reading (REQD = 0)): Figure title changed
		544	Figure 15.17 Edge Detection Timing (Rising Edge (HIEN = 1), DACK Output is Active during Writing (REQD = 1)): Figure title changed
		545	Figure 15.18 Level Detection Timing (High-Level Detection (HIEN = 1), DACK Output is Active during Reading (REQD = 0)): Figure title changed
		545	Figure 15.19 Level Detection Timing (High-Level Detection (HIEN = 1), DACK Output is Active during Writing (REQD = 1)): Figure title changed
		558	15.4.2 DMA Transfer Completion Interrupts: Description changed
		558	15.4.2 DMA Transfer Completion Interrupts: Caution added
		562	Table 15.26 DMA Transfer Setting Example 2: Setting Example 2 at the bottom, changed
		563	Figure 15.38 Setting Example 2: Flow changed
		568	Table 15.32 Descriptor Settings: Descriptor 1, Descriptor 2, and Descriptor 3 values of CFG (Configuration), changed
		Section 18 Multi-Function Pin Controller (MPC)	
		618 to 638	Table 18.1 List of Multiplexed Pin Configurations, RD (output) in the Pin Function column for External bus controller corrected to RD# (output)
		640	18.2.2 P0n Pin Function Control Register (P0nPFS) (n = 0 to 7), description corrected
		641	18.2.3 P1n Pin Function Control Register (P1nPFS) (n = 0 to 7), description corrected
		643	18.2.4 P2n Pin Function Control Register (P2nPFS) (n = 0 to 7), description corrected
		644	18.2.5 P3n Pin Function Control Register (P3nPFS) (n = 0 to 7), description corrected
		646	18.2.6 P4n Pin Function Control Register (P4nPFS) (n = 0 to 7), description corrected
		648	18.2.7 P5n Pin Function Control Register (P5nPFS) (n = 0 to 6), description corrected
		649	18.2.8 P6n Pin Function Control Register (P6nPFS) (n = 0 to 7), description corrected
		651	18.2.9 P7n Pin Function Control Register (P7nPFS) (n = 0 to 7), description corrected
		652	18.2.10 P8n Pin Function Control Register (P8nPFS) (n = 0 to 7), description corrected
		654	18.2.11 P9n Pin Function Control Register (P9nPFS) (n = 0 to 7), description corrected
		655	18.2.12 PAn Pin Function Control Register (PAnPFS) (n = 0 to 7), description corrected
		656	18.2.13 PBn Pin Function Control Register (PBnPFS) (n = 0 to 7), description corrected

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	658	18.2.14 PCn Pin Function Control Register (PCnPFS) (n = 0 to 7), description corrected
		660	18.2.15 PDn Pin Function Control Register (PDnPFS) (n = 0 to 7), description corrected
		662	18.2.16 PEn Pin Function Control Register (PEnPFS) (n = 0 to 7), description corrected
		663	18.2.17 PFn Pin Function Control Register (PFnPFS) (n = 5 to 7), description corrected
		665	18.2.18 PGn Pin Function Control Register (PGnPFS) (n = 0 to 7), description corrected
		666	18.2.19 PHn Pin Function Control Register (PHnPFS) (n = 0 to 7), description corrected
		667	18.2.20 PJn Pin Function Control Register (PJnPFS) (n = 0 to 7), description corrected
		668	18.2.21 PKn Pin Function Control Register (PKnPFS) (n = 0 to 7), description corrected
		669	18.2.22 PLn Pin Function Control Register (PLnPFS) (n = 0 to 7), description corrected
		670	18.2.23 PMn Pin Function Control Register (PMnPFS) (n = 0 to 7), description corrected
		671	18.2.24 PNn Pin Function Control Register (PNnPFS) (n = 0 to 7), description corrected
		672	18.2.25 PPn Pin Function Control Register (PPnPFS) (n = 0 to 7), description corrected
		673	18.2.26 PRn Pin Function Control Register (PRnPFS) (n = 0 to 7), description corrected
		674	18.2.27 PSn Pin Function Control Register (PSnPFS) (n = 0 to 7), description corrected
		675	18.2.28 PTn Pin Function Control Register (PTnPFS) (n = 0 to 7), description corrected
		676	18.2.29 PUn Pin Function Control Register (PUnPFS) (n = 0 to 7), description corrected
		678	Table 18.39 Register Settings, Note 1 corrected
		Section 19 Multi-Function Timer Pulse Unit (MTU3a)	
		693	19.2.2 Timer Control Register 2 (TCR2), description corrected
		702	19.2.6 Timer I/O Control Register (TIOR), description corrected
		732	19.2.16 Timer Longword General Register n (TGRnLW) (n = A, B), description corrected
		735	19.2.18 Timer Synchronous Register (TSYR), description corrected
		737	19.2.19 Timer Counter Synchronous Start Register (TCSYSTR), address corrected
		755	19.2.33 Noise Filter Control Register n (NFCRn) (n = 0 to 4, 6, 7, 8, C), • NFCRC, address corrected
		Section 22 16-Bit Timer Pulse Unit (TPUa)	
		1127	22.2.4 Timer Interrupt Enable Register (TIER), bit table: Note 1 corrected
		Section 23 Programmable Pulse Generator (PPG)	
		1199	Table 23.2 List of Functions of the PPG, title corrected
		1201	Table 23.3 Pin Configuration of the PPG, title corrected
		Section 26 Watchdog Timer (WDTA)	
		—	Heading title: 26.1.1 Block Diagram, deleted
		1273	Figure 26.1 WDT Block Diagram: Description on the top was changed.
		1273	Figure 26.1 WDT Block Diagram, changed
		1274	26.2.1 WDT Refresh Register (WDTRR): Note added to the value after reset
		1275	26.2.2 WDT Control Register (WDTCR): Note added to the value after reset
		1279	26.2.3 WDT Status Register (WDTSR): Note added to the value after reset
		1280	26.2.4 WDT Reset Control Register (WDTRCR): Note added to the value after reset
		—	26.5.1 Clock Division Ratio Setting, deleted
		Section 27 Independent Watchdog Timer (IWDTa)	
		—	Heading title: 27.1.1 Block Diagram, deleted
		1288	27.1.1 Block Diagram: Description changed
		1289	Figure 27.1 IWDT Block Diagram, changed
		Section 28 Ethernet MAC (ETHERC)	
		1308	Figure 28.1 Block Diagram of the ETHERC, description above the figure corrected
		1308	Figure 28.1 Block Diagram of the ETHERC, title corrected

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	1308	Figure 28.2 Block Diagram of the ETHERC (for Products Incorporating an R-IN Engine), title corrected
		1309	Table 28.2 Input/Output Pins of the ETHERC, description above the table corrected
		1309	Table 28.2 Input/Output Pins of the ETHERC, title corrected
		1309	Table 28.2 Input/Output Pins of the ETHERC, pin name: PHYLINK2 deleted
		1313	28.2.1.4 MAC Select Register (MACSEL), description corrected
		1313	Table 28.3 MAC Function Selection Method (for Products Incorporating an R-IN Engine), description in the Media I/F Port 1 column for 011 corrected
		1314	28.2.1.5 MII Control Register (MII_CTRLn) (n = 0 to 2), bit chart: RMII_RX_ER_EN deleted
		1314	28.2.1.5 MII Control Register (MII_CTRLn) (n = 0 to 2), bit table: symbol, bit name, and functional description of b9 corrected
		1316	28.2.2.1 MIIM Register (GMAC_MIIM), description corrected
		1317	28.2.2.2 TX ID Register (GMAC_TXID), bit chart: TXID corrected
		1325	28.2.2.8 PAUSE Packet Data Register (GMAC_PAUSEn) (n = 1 to 5), bit chart: PPDATA1 corrected
		1325	28.2.2.8 PAUSE Packet Data Register (GMAC_PAUSEn) (n = 1 to 5), bit chart: ETHERC.GMAC_PAUSE1, PPDATA1 corrected
		1325	28.2.2.8 PAUSE Packet Data Register (GMAC_PAUSEn) (n = 1 to 5), bit chart: ETHERC.GMAC_PAUSE2, PPDATA2 corrected
		1326	28.2.2.8 PAUSE Packet Data Register (GMAC_PAUSEn) (n = 1 to 5), bit chart: ETHERC.GMAC_PAUSE3, PPDATA3 corrected
		1326	28.2.2.8 PAUSE Packet Data Register (GMAC_PAUSEn) (n = 1 to 5), bit chart: ETHERC.GMAC_PAUSE4, PPDATA4 corrected
		1326	28.2.2.8 PAUSE Packet Data Register (GMAC_PAUSEn) (n = 1 to 5), bit chart: ETHERC.GMAC_PAUSE5, PPDATA5 corrected
		1328	28.2.2.11 MAC Address Registers (GMAC_ADRnA and GMAC_ADRnB) (n = 0 to 15), o GMAC_ADRnB: bit table corrected
		1336	28.2.3.1 Hardware Function System Call Register (SYSC), title corrected
		1336	28.2.3.1 Hardware Function System Call Register (SYSC), bit table: b15 to b0 corrected
		1337	28.2.3.2 Hardware Function Argument Register (Rn) (n = 4 to 7), • R4, bit chart: R4B corrected
		1337	28.2.3.2 Hardware Function Argument Register (Rn) (n = 4 to 7), • R5, bit chart: R5B corrected
		1338	28.2.3.2 Hardware Function Argument Register (Rn) (n = 4 to 7), • R6, bit chart: R6B corrected
		1338	28.2.3.2 Hardware Function Argument Register (Rn) (n = 4 to 7), • R7, bit chart: R7B corrected
		1339	28.2.3.3 Hardware Function Command Register(CMD), added
		1340	28.2.3.4 Hardware Function Return Value Register (R0, R1), • R0, bit chart: R0B corrected
		1340	28.2.3.4 Hardware Function Return Value Register (R0, R1), • R1, bit chart: R1B corrected
		1341	28.2.3.5 Hardware Function Type Register (C0TYPE), added
		1341	28.2.3.6 Hardware Function State Register (C0STAT), added
		1342	28.3.1 Hardware Functions, added
		1366	28.3.2 Interrupts, added
		1369	28.3.3.1 Initial Settings, description corrected
		1376	28.3.4.6 (1) Receive frame information, table listing the fields of the receive frame information: entries in the Explanation column for MARSTAT[2:0] corrected
		Section 29 Ethernet Switch	
		1382	Figure 29.1 Block Diagram of the Ethernet Interface, description corrected
		1382	Figure 29.1 Block Diagram of the Ethernet Interface, title corrected
		1382	Figure 29.2 Block Diagram of the Ethernet Interface (for Products Incorporating an R-IN Engine), title corrected

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	1398	29.2.2.12 Output Queue Congestion Status Register (QMGR_CGS_STAT), bit chart, b31 to b3: value after reset corrected
		1399	29.2.2.13 Internal Queue Interface Status Register (QMGR_IFACE_STAT), bit chart, b31 to b19, b15 to b3: value after reset corrected
		1410	29.2.3.2 Learning Record B Register (LRN_REC_B), bit chart, b31 to b28: value after reset corrected
		1410	29.2.3.3 Learning Data Status Register (LRN_STATUS), bit chart, b31 to b1: value after reset corrected
		1415	29.2.4.4 MAC Status Register n (MAC_STATUSn) (Shared) (n = 0, 1), bit chart, b31 to b15, b13, b11, b9, b7 to b0: value after reset corrected
		1418	29.2.4.6 (2) MAC TX Statistic Counters, description for the address 0C 81A8h + 2000h*n in the table corrected
		1433	29.2.5.18 Timer Pulse Width Register (SWTMWTH), Note 2 deleted
		1436	29.2.6.2 DLR Status Register (DLR_STATUS), bit chart, b23 to 18, b7: value after reset corrected
		1443	29.2.6.9 DLR Supervisor MAC Address High Register (SUPR_MAChi), bit chart, b31 to b24: value after reset corrected
		1444	29.2.6.10 DLR Ring Status/VLAN Register (STATE_VLAN), bit chart, b15 to b9: value after reset corrected
		1446	29.2.6.14 DLR Sub Type/Protocol Version Register (ETH_STYP _VER), bit chart, b31 to b24: value after reset corrected
		1481	29.4.2 Switch Initialization, description corrected
		1482	Table 29.22 Examples of Initial Settings of Switch Engine, register at address A00B F118h added
		Section 30 EtherCAT Slave Controller (Only for Products Incorporating an R-IN Engine)	
		1489	Figure 30.1 Block Diagram of the EtherCAT Slave Controller, description above the figure corrected
		1489	Figure 30.1 Block Diagram of the EtherCAT Slave Controller, title corrected
		1489	Table 30.2 Input/Output Pins of the EtherCAT Slave Controller (excluding PHY MII pins), description above the figure corrected
		1489	Table 30.2 Input/Output Pins of the EtherCAT Slave Controller (excluding PHY MII pins), title corrected
		1493	30.3.1 EtherCAT PHY Offset Address Setting Register (CATOFFADD), bit chart, b31 to b5: value after reset corrected
		1493	30.3.1 EtherCAT PHY Offset Address Setting Register (CATOFFADD), bit table: b31 to b5 added
		1494	30.3.2 EtherCAT Operation Mode Setting Register (CATEMMD), bit chart, b31 to b1: value after reset corrected
		1494	30.3.2 EtherCAT Operation Mode Setting Register (CATEMMD), bit table: b31 to b1 added
		1495	30.3.3 EtherCAT TXC Shift Setting Register (CATTXCSFT), description corrected
		1495	30.3.3 EtherCAT TXC Shift Setting Register (CATTXCSFT), bit chart, b31 to b4: value after reset corrected
		1495	30.3.3 EtherCAT TXC Shift Setting Register (CATTXCSFT), bit table: b31 to b4 added
		1499	30.4.8 ESC Features Supported Register (FEATURE), bit chart, b15 to b12, b5 to b4, b1: value after reset corrected
		1499	30.4.8 ESC Features Supported Register (FEATURE), bit table: b15 to b12, b5, b4, b1 added
		1500	30.5.2 Configured Station Alias Register (STATION_ALIAS), bit table: entries in the PDI and ECT columns for b15 to b0 corrected
		1501	30.6.1 Write Register Enable Register (WR_REG_ENABLE), bit chart, b7 to b1: value after reset corrected
		1501	30.6.1 Write Register Enable Register (WR_REG_ENABLE), bit table: b7 to b1 added
		1501	30.6.2 Write Register Protection Register (WR_REG_PROTECT), bit chart, b7 to b1: value after reset corrected
		1501	30.6.2 Write Register Protection Register (WR_REG_PROTECT), bit table: b7 to b1 added

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	1502	30.6.3 ESC Write Enable Register (ESC_WR_ENABLE), bit chart, b7 to b1: value after reset corrected
		1502	30.6.3 ESC Write Enable Register (ESC_WR_ENABLE), bit table: b7 to b1 added
		1502	30.6.4 ESC Write Protection Register (ESC_WR_PROTECT), bit chart, b7 to b1: value after reset corrected
		1502	30.6.4 ESC Write Protection Register (ESC_WR_PROTECT), bit table: b7 to b1 added
		1503	30.7.1 ESC Reset ECAT Register (ESC_RESET_ECAT), When read: ESC_RESET_ECAT_R, bit chart, b7 to b2: value after reset corrected
		1503	30.7.1 ESC Reset ECAT Register (ESC_RESET_ECAT), When read: ESC_RESET_ECAT_R, bit table: b7 to b2 added
		1504	30.7.2 ESC Reset PDI Register (ESC_RESET_PDI), When read: ESC_RESET_PDI_R, bit chart: b7 to b2: value after reset corrected
		1504	30.7.2 ESC Reset PDI Register (ESC_RESET_PDI), When read: ESC_RESET_PDI_R, bit table: b7 to b2 added
		1505	30.7.3 ESC DL Control Register (ESC_DL_CONTROL), bit chart, b31 to b25, b23 to b19, b7 to b2: value after reset corrected
		1505	30.7.3 ESC DL Control Register (ESC_DL_CONTROL), bit table: b31 to b25, b23 to b19, b7 to b2 added
		1507	30.7.5 ESC DL Status Register (ESC_DL_STATUS), bit chart, b3: value after reset corrected
		1507	30.7.5 ESC DL Status Register (ESC_DL_STATUS), bit table: b3 added
		1509	30.8.1 AL Control Register (AL_CONTROL), bit chart, b15 to b5: value after reset corrected
		1509	30.8.1 AL Control Register (AL_CONTROL), bit table: b15 to b5 added
		1510	30.8.2 AL Status Register (AL_STATUS), bit chart, b15 to b5: value after reset corrected
		1510	30.8.2 AL Status Register (AL_STATUS), bit table: b15 to b5 added
		1511	30.8.4 RUN LED Override Register (RUN_LED_OVERRIDE), bit chart, b7 to b5: value after reset corrected
		1511	30.8.4 RUN LED Override Register (RUN_LED_OVERRIDE), bit table: b7 to b5 added
		1512	30.8.5 ERR LED Override Register (ERR_LED_OVERRIDE), bit chart, b7 to b5: value after reset corrected
		1512	30.8.5 ERR LED Override Register (ERR_LED_OVERRIDE), bit table: b7 to b5 added
		1516	30.9.5 Extended PDI Configuration Register (EXT_PDI_CONFIG), bit chart, b15 to b1: value after reset corrected
		1516	30.9.5 Extended PDI Configuration Register (EXT_PDI_CONFIG), bit table: b15 to b1 added
		1518	30.10.3 ECAT Event Request Register (ECAT_EVENT_REQ), bit chart, b15 to b12, b1: value after reset corrected
		1518	30.10.3 ECAT Event Request Register (ECAT_EVENT_REQ), bit table: b15 to b12, b1 added
		1519	30.10.4 AL Event Request Register (AL_EVENT_REQ), bit chart, b31 to b16, b7, b5: value after reset corrected
		1519	30.10.4 AL Event Request Register (AL_EVENT_REQ), bit chart, b14, symbol corrected
		1519	30.10.4 AL Event Request Register (AL_EVENT_REQ), bit table: b31 to b16, b7, b5 added
		1525	30.12.4 Watchdog Status Process Data Register (WDS_DATA), bit chart, b15 to b2: value after reset corrected
		1525	30.12.4 Watchdog Status Process Data Register (WDS_DATA), bit table: b15 to b2 added
		1527	30.13.1 EEPROM Configuration Register (EEP_CONF), bit chart, b7 to b2: value after reset corrected
		1527	30.13.1 EEPROM Configuration Register (EEP_CONF), bit table: b7 to b2 added
		1527	30.13.2 EEPROM PDI Access State Register (EEP_STATE), bit chart, b7 to b1: value after reset corrected
		1527	30.13.2 EEPROM PDI Access State Register (EEP_STATE), bit table: b7 to b1 added
		1528	30.13.3 EEPROM Control/Status Register (EEP_CONT_STAT), bit chart, b5 to b1: value after reset corrected

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	1528	30.13.3 EEPROM Control/Status Register (EEP_CONT_STAT), bit table: b5 to b1 added
		1530	30.14.1 MII Management Control/Status Register (MII_CONT_STAT), bit chart, b12 to b10: value after reset corrected
		1530	30.14.1 MII Management Control/Status Register (MII_CONT_STAT), bit table: b12 to b10 added
		1531	30.14.2 PHY Address Register (PHY_ADR), bit chart, b7 to b5: value after reset corrected
		1531	30.14.2 PHY Address Register (PHY_ADR), bit table: b7 to b5 added
		1531	30.14.3 PHY Register Address Register (PHY_REG_ADR), bit chart, b7 to b5: value after reset corrected
		1531	30.14.3 PHY Register Address Register (PHY_REG_ADR), bit table: b7 to b5 added
		1532	30.14.5 MII Management ECAT Access State Register (MII_ECAT_ACS_STAT), bit chart, b7 to b1: value after reset corrected
		1532	30.14.5 MII Management ECAT Access State Register (MII_ECAT_ACS_STAT), bit table: b7 to b1 added
		1533	30.14.6 MII Management PDI Access State Register (MII_PDI_ACS_STAT), bit chart, b7 to b2: value after reset corrected
		1533	30.14.6 MII Management PDI Access State Register (MII_PDI_ACS_STAT), bit table: b7 to b2 added
		1534	30.14.7 PHY Port Status n Register (PHY_STATUSn), bit chart, b7, b6: value after reset corrected
		1534	30.14.7 PHY Port Status n Register (PHY_STATUSn), bit table: b7, b6 added
		1535	30.15.1 FMMU Logical Start Address m Register (FMMUm_L_START_ADR), address corrected
		1535	30.15.2 FMMU Length m Register (FMMUm_LEN), address corrected
		1536	30.15.3 FMMU Logical Start Bit m Register (FMMUm_L_START_BIT), address corrected
		1536	30.15.3 FMMU Logical Start Bit m Register (FMMUm_L_START_BIT), bit chart, b7 to b3: value after reset corrected
		1536	30.15.3 FMMU Logical Start Bit m Register (FMMUm_L_START_BIT), bit table: b7 to b3 added
		1536	30.15.4 FMMU Logical Stop Bit m Register (FMMUm_L_STOP_BIT), address corrected
		1536	30.15.4 FMMU Logical Stop Bit m Register (FMMUm_L_STOP_BIT), bit chart, b7 to b3: value after reset corrected
		1536	30.15.4 FMMU Logical Stop Bit m Register (FMMUm_L_STOP_BIT), bit table: b7 to b3 added
		1537	30.15.5 FMMU Physical Start Address m Register (FMMUm_P_START_ADR), address corrected
		1537	30.15.6 FMMU Physical Start Bit m Register (FMMUm_P_START_BIT), address corrected
		1537	30.15.6 FMMU Physical Start Bit m Register (FMMUm_P_START_BIT), bit chart, b7 to b3: value after reset corrected
		1537	30.15.6 FMMU Physical Start Bit m Register (FMMUm_P_START_BIT), bit table: b7 to b3 added
		1538	30.15.7 FMMU Type m Register (FMMUm_TYPE), address corrected
		1538	30.15.7 FMMU Type m Register (FMMUm_TYPE), bit chart, b7 to b2: value after reset corrected
		1538	30.15.7 FMMU Type m Register (FMMUm_TYPE), bit table: b7 to b2 added
		1538	30.15.8 FMMU Activate m Register (FMMUm_ACT), address corrected
		1538	30.15.8 FMMU Activate m Register (FMMUm_ACT), bit chart, b7 to b1: value after reset corrected
		1538	30.15.8 FMMU Activate m Register (FMMUm_ACT), bit table: b7 to b1 added
		1539	30.16.1 SyncManager Physical Start Address m Register (SMm_P_START_ADR), address corrected
		1539	30.16.2 SyncManager Length m Register (SMm_LEN), address corrected
		1540	30.16.3 SyncManager Control m Register (SMm_CONTROL), address corrected
		1540	30.16.3 SyncManager Control m Register (SMm_CONTROL), bit chart, b7: value after reset corrected
		1540	30.16.3 SyncManager Control m Register (SMm_CONTROL), bit table: b7 added
		1541	30.16.4 SyncManager Status m Register (SMm_STATUS), address corrected

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	1541	30.16.4 SyncManager Status m Register (SMm_STATUS), bit chart, b2: value after reset corrected
		1541	30.16.4 SyncManager Status m Register (SMm_STATUS), bit table: b2 added
		1542	30.16.5 SyncManager Activate m Register (SMm_ACT), address corrected
		1542	30.16.5 SyncManager Activate m Register (SMm_ACT), bit chart, b5 to b2: value after reset corrected
		1542	30.16.5 SyncManager Activate m Register (SMm_ACT), bit table: b5 to b2 added
		1543	30.16.6 SyncManager PDI Control m Register (SMm_PDI_CONT), address corrected
		1543	30.16.6 SyncManager PDI Control m Register (SMm_PDI_CONT), bit chart, b7 to b2: value after reset corrected
		1543	30.16.6 SyncManager PDI Control m Register (SMm_PDI_CONT), bit table: b7 to b2 added
		1544	30.17.1.1 Receive Time Port 0 Register (DC_RCV_TIME_PORT0), bit chart, b31 to b0: value after reset added
		1544	30.17.1.2 Receive Time Port 1 Register (DC_RCV_TIME_PORT1), bit chart, b31 to b0: value after reset added
		1550	30.17.2.6 Speed Counter Start Register (DC_SPEED_COUNT_START), bit chart, b15: value after reset corrected
		1550	30.17.2.6 Speed Counter Start Register (DC_SPEED_COUNT_START), bit table: b15 added
		1551	30.17.2.8 System Time Difference Filter Depth Register (DC_SYS_TIME_DIFF_FIL_DEPTH), bit chart, b7 to b4: value after reset corrected
		1551	30.17.2.8 System Time Difference Filter Depth Register (DC_SYS_TIME_DIFF_FIL_DEPTH), bit table: b7 to b4 added
		1551	30.17.2.9 Speed Counter Filter Depth Register (DC_SPEED_COUNT_FIL_DEPTH), bit chart, b7 to b4: value after reset corrected
		1551	30.17.2.9 Speed Counter Filter Depth Register (DC_SPEED_COUNT_FIL_DEPTH), bit table: b7 to b4 added
		1552	30.17.3.1 Cyclic Unit Control Register (DC_CYC_CONT), bit chart, b7, b3 to b1: value after reset corrected
		1552	30.17.3.1 Cyclic Unit Control Register (DC_CYC_CONT), bit table: b7, b3 to b1 added
		1554	30.17.4.2 SYNC Signal Pulse Length Register (DC_PULSE_LEN), bit chart, b13, b10 to b8, b4: value after reset corrected
		1554	30.17.4.3 Activation Status Register (DC_ACT_STAT), bit chart, b7 to b3: value after reset corrected
		1554	30.17.4.3 Activation Status Register (DC_ACT_STAT), bit table: b7 to b3 added
		1555	30.17.4.4 SYNC0 Status Register (DC_SYNC0_STAT), bit chart, b7 to b1: value after reset corrected
		1555	30.17.4.4 SYNC0 Status Register (DC_SYNC0_STAT), bit table: b7 to b1 added
		1555	30.17.4.5 SYNC1 Status Register (DC_SYNC1_STAT), bit chart, b7 to b1: value after reset corrected
		1555	30.17.4.5 SYNC1 Status Register (DC_SYNC1_STAT), bit table: b7 to b1 added
		1559	30.17.5.1 Latch 0 Control Register (DC_LATCH0_CONT), bit chart, b7 to b1: value after reset corrected
		1559	30.17.5.2 Latch 1 Control Register (DC_LATCH1_CONT), bit chart, b7 to b1: value after reset corrected
		1559	30.17.5.2 Latch 1 Control Register (DC_LATCH1_CONT), bit table: b7 to b1 added
		1560	30.17.5.3 Latch 0 Status Register (DC_LATCH0_STAT), bit chart, b7 to b3: value after reset corrected
		1560	30.17.5.3 Latch 0 Status Register (DC_LATCH0_STAT), bit table: b7 to b3 added
		1560	30.17.5.4 Latch 1 Status Register (DC_LATCH1_STAT), bit chart, b7 to b3: value after reset corrected
		1560	30.17.5.4 Latch 1 Status Register (DC_LATCH1_STAT), bit table: b7 to b3 added

		1591	31.3.1.12 HcBulkCurrentED Register, bit chart: symbol BulkCurrentED corrected
		1591	31.3.1.12 HcBulkCurrentED Register, bit table, symbol of b31 to b4: BulkCurrentED corrected
		1592	31.3.1.13 HcDoneHead Register, bit chart: symbol DoneHead corrected
		1592	31.3.1.13 HcDoneHead Register, bit table, symbol of b31 to b4: DoneHead corrected
		1608	31.3.2.4 HCSP_PORTROUTE Register, bit chart: symbol Companion Port Route corrected
		1615	31.3.2.9 CTRLDSSEGMENT Register, bit chart: symbol CTRLDSSEGMENT corrected
		1615	31.3.2.10 PERIODICLISTBASE Register, bit chart: symbol BaseAddress (Low) corrected
		1615	31.3.2.10 PERIODICLISTBASE Register, bit table, symbol of b31 to b12: BaseAddress (Low) corrected
		1616	31.3.2.11 ASYNCLISTADDR Register, bit chart: symbol LPL corrected
		1616	31.3.2.11 ASYNCLISTADDR Register, bit table, symbol of b31 to b5: LPL corrected
		1625	31.3.3.4 Offset 0Ch Register (Cache Line Size, Latency Timer, Header Type, BIST), address corrected
		1626	31.3.3.5 Offset 10h Register (OHCI Base Address), bit chart: symbol OHCI Base Address corrected
		1626	31.3.3.5 Offset 10h Register (OHCI Base Address), bit table, symbol of b31 to b12: OHCI Base Address corrected
		1638	31.3.4.5 Offset 10h Register (EHCI Base Address), bit chart: symbol EHCI Base Address corrected
		1638	31.3.4.5 Offset 10h Register (EHCI Base Address), bit table, symbol of b31 to b4: EHCI Base Address corrected
		—	31.3.4.15 Offset F0h Register (Transceiver characteristic), deleted
		—	31.3.4.16 Offset F4h Register (UTMI + Operation Mode Control), deleted
		1648	31.3.5.5 Offset 10h Register (AHB-PCI Bridge Base Address), bit chart: symbol PCICOM_BASEADR corrected
		1648	31.3.5.5 Offset 10h Register (AHB-PCI Bridge Base Address), bit table, symbol of b31 to b10: PCICOM_BASEADR corrected
		1649	31.3.5.6 Offset 14h Register (PCI-AHB WIN1 Base Address), bit chart: symbol PCI_WIN1_BASEADR corrected
		1649	31.3.5.6 Offset 14h Register (PCI-AHB WIN1 Base Address), bit table, symbol of b31 to b28, PCI_WIN1_BASEADR: functional description corrected
		—	31.3.5.7 Offset 18h Register (PCI-AHB WIN2 Base Address), deleted
		1651	31.3.6.1 PCIAHB_WIN1_CTR Register, bit chart: symbol AHB_BASEADR corrected
		1651	31.3.6.1 PCIAHB_WIN1_CTR Register, bit table, symbol of b31 to b2: AHB_BASEADR corrected
		1652	31.3.6.2 AHBPCI_WIN1_CTR Register, bit chart: symbol PCIWIN1_BASEADR corrected
		1652	31.3.6.2 AHBPCI_WIN1_CTR Register, bit table, symbol of b31 to b11: PCIWIN1_BASEADR corrected
		1653	31.3.6.3 AHBPCI_WIN2_CTR Register, address corrected
		1653	31.3.6.3 AHBPCI_WIN2_CTR Register, bit chart: symbol PCIWIN2_BASEADR corrected
		1653	31.3.6.3 AHBPCI_WIN2_CTR Register, bit table, symbol of b31 to b16: PCIWIN2_BASEADR corrected
		1656	31.3.6.5 PCI_INT_STATUS Register, address corrected
		1659	31.3.6.7 USBCTR Register, bit table: functional description of b9 corrected
		1679	Figure 31.13 Initial Setting Sequence, Release write protection: (BOWI): MPC.PWPR[7] = 0: bit name corrected

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	1679	Figure 31.13 Initial Setting Sequence, Release write protection: (PFSWE): MPC.PWPR[6] = 1: bit name corrected
		1679	Figure 31.13 Initial Setting Sequence, PCIAHB_WIN1_CTR Register: Setting of endian for PCI transfer deleted
		1679	Figure 31.13 Initial Setting Sequence, PCIAHB_WIN1_CTR Register: setting of 16 beats max. for prefetch corrected
		Section 32 USB 2.0 HS Function Module (USBf)	
		1682	32.1 Overview, description corrected
		1682 to 1683	Table 32.1 Specifications of the USB Module, title corrected
		1683	32.1.1 Block Diagram, deleted
		1683	Figure 32.1 Block Diagram of the USB Module, title corrected
		1688	32.2.1.2 System Configuration Control Register 1 (SYSCFG1), bit chart, b11 to b8: value after hardware reset corrected
		1689	32.2.1.3 System Configuration Status Register (SYSSTS0), description of Line Status Monitor Bits (LNST) below the bit table corrected
		1694	32.2.5.1 CFIFO Port Register (CFIFO) D0FIFO Port Register (D0FIFO) D1FIFO Port Register (D1FIFO) bit chart: symbol FIFOPORT corrected
		1727	32.2.12.2 DCP Control Register (DCPCTR), bit table, b14 to b13, b11: functional description corrected
		1730	32.2.13.1 Pipe Window Select Register (PIPESEL), bit chart, Note 1 deleted
		1742	32.2.14.1 PIPE1 Control Register (PIPE1CTR) PIPE2 Control Register (PIPE2CTR) PIPE3 Control Register (PIPE3CTR) PIPE4 Control Register (PIPE4CTR) PIPE5 Control Register (PIPE5CTR) bit table, b13: functional description corrected
		1748	32.2.14.2 PIPE6 Control Register (PIPE6CTR) PIPE7 Control Register (PIPE7CTR) PIPE8 Control Register (PIPE8CTR) PIPE9 Control Register (PIPE9CTR) bit table, b13: functional description corrected
		1754	Table 32.18 List of Registers that can be Written by Software when SUSPM = 0 Register name for address A006 0002h corrected Address A006 0032h deleted Register name for address A006 0102h corrected Note 1 deleted
		1755	32.2.17.1 D0FIFO Continuous Transfer Port Register n (D0FIFOBn) (n = 0 to 7) D1FIFO Continuous Transfer Port Register n (D1FIFOBn) (n = 0 to 7) bit chart: symbol FIFOPORT corrected
		1757	Figure 32.4 Startup Sequence, bit name corrected
		1759	Table 32.22 Operations for USBf Interrupt Output, description above the table corrected
		1761	Figure 32.6 Interrupt Configuration Diagram, corrected
		1775	32.11.1 Isochronous Transfer Error Detection, (3) Maximum packet size over, title corrected
		Section 33 Serial Communications Interface with FIFO (SCIFA)	
		1782	Heading title: 33.2 Input/Output Pins, deleted
		1791	33.2.8 Bit Rate Register (BRR): Note deleted
		1794	Table 33.9 Maximum Bit Rates with External Clock Input (in Clock Synchronous Mode), totally changed
		1800	33.3.12 Serial Port Register (SPTR): Description changed
		1800	33.3.12 Serial Port Register (SPTR) Values after reset of symbols: RTS2DT, CTS2DT, SCKDT, and SPB2DT in the bit chart, changed

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	Section 34 I2C Bus Interface (RIIC)	
		1835	Table 34.2Pin Configuration: Description on the top was changed.
		1845	34.2.5 I2C Bus Mode Register 3 (ICMR3) Symbol of b7 was changed in the bit chart.
		1862	Table 34.5 Examples of ICBRH/ICBRL Settings for Transfer Rate: Note changed
		1905	Table 34.6 Interrupt Sources: Table heading, Priority, deleted
		Section 35 CAN Interface (RSCAN)	
		1909	35.1.1 Functional Overview, description corrected
		1909, 1910	Table 35.1 RSCAN Module Specifications, title corrected
		—	35.1.2 Block Diagram, section title deleted
		1911	Figure 35.1 RSCAN Module Block Diagram, title corrected
		1936	35.2.13 Reception Rule ID Register (RSCAN0GAFLIDj) (j = 0 to 15), bit chart: symbol GAFLID corrected
		1937	35.2.14 Reception Rule Mask Registers (RSCAN0GAFLMj) (j = 0 to 15), bit chart: symbol GAFLIDM corrected
		1940	35.2.16 Reception Rule Pointer 1 Registers (RSCAN0GAFLP1j) (j = 0 to 15), bit chart: symbol GAFLFDP corrected
		1940	35.2.16 Reception Rule Pointer 1 Registers (RSCAN0GAFLP1j) (j = 0 to 15), bit table: symbol of b25 to b8 corrected
		1943	35.2.19 Receive Buffer ID Registers (RSCAN0RMIDq) (q = 0 to 31), bit chart: symbol RMID corrected
		1952	35.2.26 Receive FIFO Buffer Access ID Registers (RSCAN0RFIDx) (x = 0 to 7), bit chart: symbol RFID corrected
		1964	35.2.33 Transmit/Receive FIFO Buffer Access ID Registers (RSCAN0CFIDk) (k = 0 to 5), bit chart: symbol CFID corrected
		1970	35.2.37 FIFO Empty Status Register (RSCAN0FESTS), bit chart, b25 to b17: value after hardware reset corrected
		1970	35.2.37 FIFO Empty Status Register (RSCAN0FESTS), bit table: symbol of b25 to b17 corrected
		1985	35.2.50 Transmit Buffer ID Registers (RSCAN0TMIDp) (p = 0 to 31), bit chart: symbol TMID corrected
		1991	35.2.55 Transmit Queue Status Registers (RSCAN0TXQSTSm) (m = 0, 1), bit chart, b12 to b8: value after reset corrected
		2002	35.2.64 RAM Test Page Access Registers (RSCAN0RPGACCr) (r = 0 to 63), bit chart: symbol RDTA corrected
		Section 37 SPI Multi I/O Bus Controller (SPIBSC)	
		2143	Table 37.1 SPIBSC Specifications: Description of Figure 37.1, Block Diagram of SPIBSC, at the bottom, changed
		—	Heading title: 37.2 Block Diagram, deleted
		—	Heading title: 37.3 Input/Output Pins, deleted
		2144	Table 37.2 Pin Configuration of the SPIBSC: Table title changed
		2145	37.4.1 Common Control Register (CMNCR) Functional description of b6 in the bit chart, changed
		2160	37.4.11 SPI Mode Address Setting Register (SMADR) Symbol: ADR was changed in the bit chart.
		2163	37.4.14 SPI Mode Read Data Register 0 (SMRDR0) Symbol: RDATA0 was changed in the bit chart.
		2163	37.4.14 SPI Mode Read Data Register 0 (SMRDR0) Value after reset was changed in the bit chart.
		2163	37.4.15 SPI Mode Write Data Register 0 (SMWDR0) Symbol: WDATA0 was changed in the bit chart.

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	Section 38 CRC Operation Units (CRC)	
		2188	38.2.1 CRC Data Input Register (CRCDIR), bit chart: symbol CRCDIR corrected
		2189	38.2.2 CRC Data Output Register (CRCDOR), bit chart: symbol CRCDOR corrected
		Section 41 ΔΣ Interface (DSMIF)	
		2244	41.2.2 UVW Status Register (UVWSTA), bit chart, symbols ERWSC, ERVSC, ERUSC: value after reset corrected
		2250	41.2.7 UVW Total Current Abnormality Detection Lower Limit Setting Register (UVWIGUNCMP), bit chart: symbol CMPUVWIGNDUNDER corrected
		2251	41.2.8 UVW Total Current Abnormality Detection Upper Limit Setting Register (UVWIGOVCMP), bit chart: symbol CMPUVWIGNDOVER corrected
		2261	41.2.22 XYZ Status Register (XYZSTA), bit chart, b6, b5: value after reset corrected
		2261	41.2.22 XYZ Status Register (XYZSTA), bit chart, symbol ERXSC: value after reset corrected
		2261	41.2.22 XYZ Status Register (XYZSTA), bit table, b6, b5: description corrected
		Section 42 Error Control Module (ECM)	
		2279	Table 42.1 Specifications of ECM: Table title changed
		2291	42.2.8 ECM Maskable Interrupt Configuration Register 0 (ECMMICFG0) Functional description of b2, b1, and b0 in the bit chart, changed
		2296	42.2.11 ECM Non-maskable Interrupt Configuration Register 0 (ECMNMICFG0) Functional description of b2, b1, and b0 in the bit chart, changed
		2301	42.2.14 ECM Internal Reset Configuration Register 0 (ECMIRCFG0) Functional description of b2, b1, and b0 in the bit chart, changed
		2306	42.2.17 ECM Error Mask Register 0 (ECMEMK0) Functional description of b2, b1, and b0 in the bit chart, changed
		2311	42.2.20 ECM Error Source Status Clear Trigger Register 0 (ECMESSTC0) Functional description of b2, b1, and b0 in the bit chart, changed
		2317	42.2.25 ECM Pseudo Error Trigger Register 0 (ECMPE0) Functional description of b2, b1, and b0 in the bit chart, changed
		2322	42.2.29 ECM Delay Timer Register (ECMDTMR): Description changed
		2324	42.2.31 ECM Delay Timer Configuration Register 0 (ECMDTMCFG0) Functional description of b2, b1, and b0 in the bit chart, changed
		2330	42.2.34 ECM Delay Timer Configuration Register 3 (ECMDTMCFG3) Functional description of b2, b1, and b0 in the bit chart, changed
		2341	42.4.1 Notes Regarding ECMCLK: Description changed
		Section 43 12-Bit A/D Converter (S12ADCa)	
		2343 to 2344	Table 43.1 Specifications of 12-Bit A/D Converter, Input channels and A/D conversion clock: Note 1 corrected to Note 3
		2375	43.2.13 A/D Sample and Hold Circuit Control Register (ADSHCR), address corrected
		2442	Figure 43.40 Procedures for Clear Operation by Software through the ADCSR.ADST Bit, “Is data transfer to EMU2 used?” deleted from the flow
		2442	Figure 43.40 Procedures for Clear Operation by Software through the ADCSR.ADST Bit, “Disable data transfer from the ADC to EMU2.” deleted from the flow
		Section 44 Temperature Sensor	
		2451	44.4.1 Module-Stop Function Setting, description deleted
		Section 45 Data Operation Circuit (DOC)	
		2452	Figure 45.1 Block Diagram of Data Operation Circuit (DOC): Figure title changed
		Section 46 RAM (Product Option)	
		2459	Table 46.1 Specifications of RAM: Description on RAM addresses (for products incorporating an R-IN engine) (for access from the Cortex-M3), changed
		2459	Table 46.1 Specifications of RAM: Caution added
		2470	46.2.8 2-Bit ECC Error Address Register (RAMDBEAD): Description changed

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	2470	46.2.8 2-Bit ECC Error Address Register (RAMDBEAD) Symbol: ADDRESS of b31 to b20 in the bit chart was changed to “—”
		2470	46.2.8 2 2-Bit ECC Error Address Register (RAMDBEAD) Symbol: ADDRESS of b19 and b18 in the bit chart was changed to “BANK”
		2470	46.2.8 2-Bit ECC Error Address Register (RAMDBEAD) Symbol: ADDRESS of b31 to b20 in the table of bits was changed to “Reserved”
		2470	46.2.8 2-Bit ECC Error Address Register (RAMDBEAD) Symbol: ADDRESS of b19 and b18 in the table of bits was changed to “BANK”
		2471	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine): Description changed
		2471	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine) Symbol: ADDRESS of b31 to b20 in the bit chart was changed to “—”
		2471	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine) Symbol: ADDRESS of b19 and b18 in the bit chart was changed to “BANK”
		2471	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine) Symbol: ADDRESS of b31 to b20 in the table of bits was changed to “Reserved”
		2471	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine) Symbol: ADDRESS of b19 and b18 in the table of bits was changed to “BANK”
		2471	46.2.9 2-Bit ECC Error Address Register (RAMDBEAD) (for Products Incorporating an R-IN Engine): Note changed
		2474	46.3.3 (1) Example of ECC error-injection setting procedure Flow procedure “Enable error injection”, changed
		2475	46.3.3 (2) Procedure for Checking ECC Operation After the flow procedure “Write 0000_0001h to the RAMEDC register”, add the procedure “Write 0000_0000h to the RAMPCMD register”.
		2475	46.3.3 (2) Procedure for Checking ECC Operation The flow procedure “Read the RAMDBEAD register to acquire the address where the error was found”, changed
		2475	46.3.3 (2) Procedure for Checking ECC Operation The flow procedure “Read the RAMDBECNT register to check the number of errors that were found”, changed
		2475	46.3.3 (2) Procedure for Checking ECC Operation The flow procedure “Write 0000_0000h to the RAMPCMD register”, deleted
		Section 47 Electrical Characteristics (Target)	
		2477	Figure 47.1 Power On/Off Sequence: Period of (2) Tdly12, corrected
		2485	Table 47.13 EXTAL Clock Timing, 25.00 ± 25 ppm: Note 1, added
		2485	Table 47.14 XTAL Clock Timing: Note 2, added

		2492	Figure 47.13 SRAM Interface Basic Bus Cycle (Software Wait 1): Figure title changed
		2493	Figure 47.14 SRAM Interface Basic Bus Cycle (Software Wait 1, External Wait 1 Inserted): Figure title changed
		2494	Figure 47.15 SRAM Interface Basic Bus Cycle (Software Wait 1, External wait Enabled (WM Bit = 0), No Idle Cycle): Figure title changed
		2517	Heading title: 47.4.5.1 I/O Port Timing, added
		2518	Heading title: 47.4.5.2 TPUa Timing, added
		2519	Heading title: 47.4.5.3 CMTW Timing, added
		2520	Heading title: 47.4.5.4 MTU3a Timing, added
		2521	Heading title: 47.4.5.5 POE3 Timing, added
		2522	Heading title: 47.4.5.6 GPTA Timing, added

Rev.	Date	Description	
		Page	Summary
0.80	Apr. 21, 2015	2523	Heading title: 47.4.5.7 A/D Converter Trigger Timing, added
		2524	Heading title: 47.4.5.8 SCIFA Timing, added
		2526	Heading title: 47.4.5.9 RSPIa Timing, added
		2530	Heading title: 47.4.5.10 SPIBSC Timing, added
		2533	Figure 47.63 SPIBSC Buffer On/Off Timing (CPHAT = 0, SPHAR = 1), added
		2534	Heading title: 47.4.5.11 RIICa Timing, added
		2534	Table 47.29 RIICa Timing: Symbol of SCL, SDA input rising time for RIICa (Standard-mode), changed
		2534	Table 47.29 RIICa Timing: Symbol of SCL, SDA input falling time for RIICa (Standard-mode), changed
		2534	Table 47.29 RIICa Timing: Symbol of SCL, SDA input rising time for RIICa (Fast-mode), changed
		2534	Table 47.29 RIICa Timing: Symbol of SCL, SDA input falling time for RIICa (Fast-mode), changed
		2536	Heading title: 47.4.5.12 Serial Sound Interface Timing, added
		2538	Heading title: 47.4.5.13 CAN Interface Timing, added
		2539	Heading title: 47.4.5.14 ETHERC Timing, added
		2539	Table 47.32 ETHERC Timing: ETHn_TXD0 to ETHn_TXD3 output delay time for ETHERC (MII), changed
		2539	Table 47.32 ETHERC Timing: ETHn_RXD0 to ETHn_RXD3 setup time for ETHERC (MII), changed
		2539	Table 47.32 ETHERC Timing: ETHn_RXD0 to ETHn_RXD3 hold time for ETHERC (MII), changed
		2543	Heading title: 47.4.5.15 Serial Management Interface, added
		2544	Heading title: 47.4.5.16 Delta-Sigma Interface Timing, added
		2547	Figure 47.83 Measurement Circuit (High Speed): Resistor symbol, deleted
		2548	Table 47.37 12-Bit A/D (Unit 0) Conversion Characteristics Description on “Channel-dedicated sample-and-hold circuits in use (AN000 to AN003), When disconnection detection assistance is in use”, changed
		2548	Table 47.37 12-Bit A/D (Unit 0) Conversion Characteristics Description on “Channel-dedicated sample-and-hold circuits in use (AN000 to AN003), When disconnection detection assistance is not in use”, added
		2550	Table 47.39 Temperature Sensor Characteristics: Typ. of output voltage, changed
0.90	Sep. 07, 2015	1. Overview	
		62	Table 1.2 Comparison of Functions for Different Packages, encoder interfaces, description changed
		64	Table 1.3 List of Products, products added
		71	Table 1.4 Pin Functions, USB_RREF, description partly changed (AVSS33USB → VSS_USB)
		72	Table 1.4 Pin Functions, the category Encoder I/F added
		75 to 82	Table 1.5 Pin Assignments (320-Pin FBGA), pin names ENCIF00 to ENCIF07 added
		87 to 96	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), Others, Encoder I/F added
		87 to 96	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), pin names ENCIF00 to ENCIF07 added
		94	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA), Bus for pin number T8, pin names changed
		3. Operating Modes	
		112	Figure 3.2 Memory Assignment of the Loader Program and Parameters for the Loader, note 4, changed
		118	Table 3.7 Status of the ARM CP15 Registers at the Time the Boot Finishes, System control auxiliary register: Setting Value at the Time the Boot Processing Finishes, changed
		4 Address Space	
		124	Figure 4.1 Memory Map, erroneous description corrected (DMA0 ' DMAC0), note 6 in the map replaced with the statement “mirror area of xxx”

Rev.	Date	Description	
		Page	Summary
0.90	Sep. 07, 2015	125	Figure 4.2 Memory Map (1-Mbyte Extended Internal SRAM), note 4 in the map replaced with the statement “mirror area of xxx”
		7. Clock Generation Circuit	
		241	7.8.9 USB Clock M (USBMCLK), description changed
		241	7.8.14 ECM Clock (ECMCLK), description changed
		14. Bus State Controller	
		434	14.4.6 SDRAM Interface, (1) SDRAM Direct Connection, description changed
		15. DMA Controller (DMACAa)	
		495	15.2.12 Channel Control Register n (CHCTRL_n), description for b0 (SETEN), a note added
		497 to 500	15.2.13 Channel Configuration Register n (CHCFG_n), description changed, description for b30 (REN) changed
		562	15.5.2 Setting Example 2 (Register Mode Software Request), Setting Example 2, Setting of CHCFG changed
		17. I/O ports	
		617	Table 17.3 Handling of Unused Pins, erroneous description corrected (ERROROUT → ERROROUT#)
		18. Multi-Function Pin Controller (MPC)	
		639	Table 18.1 List of Multiplexed Pin Configurations, Module/Function, Encoder I/F added
		645	18.2.5 P3n Pin Function Control Register (P3nPFS), Value after reset changed, Table 18.6 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, value after reset changed
		646	18.2.5 P3n Pin Function Control Register (P3nPFS), Table 18.7 Register Settings for the Input/Output Function in the 176-Pin QFP Pin, PSEL[5:0] Setting, value after reset changed
		650	18.2.8 P6n Pin Function Control Register (P6nPFS) Table 18.12 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, 011110b, setting for the P67 pin, changed
		652	18.2.9 P7n Pin Function Control Register (P7nPFS) (n = 0 to 7) Table 18.14 Register Settings for the Input/Output Function in the 320-Pin BGA and 176-Pin QFP Pins, PSEL[5:0] Setting, 101011b added
		655	18.2.11 P9n Pin Function Control Register (P9nPFS) Table 18.17 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, 01011b added
		656	18.2.12 PAn Pin Function Control Register (PAnPFS) (n = 0 to 7) Table 18.18 Register Settings for the Input/Output Function in the 320-Pin BGA and 176-Pin QFP Pins, PSEL[5:0] Setting, 101011b added
		673	18.2.25 PPn Pin Function Control Register (PPnPFS) Table 18.34 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, 01011b added
		674	18.2.26 PRn Pin Function Control Register (PRnPFS) Table 18.35 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, 101011b added
		675	18.2.27 PSn Pin Function Control Register (PSnPFS) Table 18.36 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, 101011b added
		676	18.2.28 PTn Pin Function Control Register (PTnPFS) Table 18.37 Register Settings for the Input/Output Function in the 320-Pin BGA Pin, PSEL[5:0] Setting, 101011b added
		20. Port Output Enable 3 (POE3)	
		All	Erroneous descriptions corrected (GTP → GPT)
		28. Ethernet MAC (ETHERC)	
		1337	28.2.3 Hardware Function Call Register, reference destination changed
		1344	28.3.3.1 Initial Settings, relocated from section 28.3.1.1, descriptions changed, Procedure for setting up the hardware functions, changed

Rev.	Date	Description	
		Page	Summary
0.90	Sep. 07, 2015	1348	Table 28.6 HWFNC_LongBuffer_Get, Return value register R0[1:0] (Result), description changed
		1369	28.3.3 Ethernet Frame Transmission Function, sequence 1, reference destination changed
		1369	28.3.3.1 Obtaining a transmit buffer, R0, value changed
		1374	28.3.4.1 Initial setup, description changed
		—	28.3.4.7 Hardware Function Call Issuance Flowchart, deleted
		29. Ethernet Switch	
		1435	29.2.6.2 DLR Status Register (DLR_STATUS), b16 and b17, value after reset changed, note 1 added
		1439	29.2.6.5 DLR Interrupt Status/ACK Register (DLR_IRQ_STAT_ACK), b7 and b8, value after reset changed
		30. EtherCAT Slave Controller (Only for Products Incorporating an R-IN Engine)	
		1499	30.5.1 Configured Station Address Register (STATION_ADR), PDI and ECAT, R/W attributes changed
		1499	30.5.2 Configured Station Alias Register (STATION_ALIAS), PDI and ECAT, R/W attributes changed
		31. USB2.0HS Host Module (USBh)	
		1570	31.1 Overview, USB2.0 Host Controller Operation, changed, AHB Bus Interface, deleted
		1572	31.1.1.1 General Precautions, (3) and (4) added (relocated from 31.1.1.4 System Implementation)
		—	31.1.1.4 System Implementation, deleted
		1578	31.3.1 OHCI Operational Registers, description added
		1604	31.3.2 EHCI Operational Registers, description added
		32. USB 2.0 HS Function Module (USBf)	
		1681	Table 32.1 Specifications of the USB Module, For High-Speed USB, description changed
		1683	32.1.1.2 Bus interface, description changed
		1684	32.1.1.4 USB Data Transfer, description changed
		All	32.2 Register Descriptions, common through the section, itemized sentences “When function controller operation is selected” deleted
		1686	32.2.1.1 System Configuration Control Register 0 (SYSCFG0), b5 (DRPD), description changed, USB Block Operation Enable (USBE), Function, a bit symbol changed (SuspendM → SUSPM)
		1688	32.2.1.3 System Configuration Status Register (SYSSTS0), Line Status Monitor Bits (LNST), description changed
		1688	Table 32.4 States of USB Data Bus Line, the column “Low-Speed Operations (only when Host Controller Operation is Selected)”, deleted
		1696	32.2.5.2 CFIFO Port Select Register (CFIFOSEL), FIFO Port Access Pipe Specification (CURPIPE) and CFIFO Port Access Bit Width Bits (MBW), descriptions changed
		1699	32.2.5.3 D0FIFO Port Select Register (D0FIFOSEL)/D1FIFO Port Select Register (D1FIFOSEL), DxFIFO Port Byte Endian Control Bit (BIGEND), description changed
		1711	32.2.8.2 BRDY Interrupt Status Register (BRDYSTS), BRDY Interrupt Status for (PIPEBRDY), description changed
		1714	32.2.8.3 NRDY Interrupt Status Register (NRDYSTS), NRDY Interrupt Status for Each Pipe (PIPENRDY), description changed
		1716	32.2.8.4 BEMP Interrupt Status Register (BEMPSTS), BEMP Interrupt Status for Each Pipe (PIPEBEMP), description changed
		1722	32.2.11.2 USB Request Value Register (USBVAL), Value (wValue), Function, description changed
		1723	32.2.11.3 USB Request Index Register (USBINDX), Index (wIndex), Function, description changed
		1724	32.2.11.4 USB Request Length Register (USBLENG), Length (wLength), Function, description changed

Rev.	Date	Description	
		Page	Summary
0.90	Sep. 07, 2015	1734	32.2.13.3 Pipe Buffer Specification Register (PIPEBUF), b7 to b0 (BUFNMB[7:0]), Function, description changed (4h-87h) → (4h-80h), Buffer number (BUFNMB), Function, description changed (0 [00h] to 8640 [87h] for 8.5-Kbyte memory) → (0 [00h] to 8192 [0x80] for 8-Kbyte memory)
		1757	32.3.3 USB Data Bus Resistor Controller, description changed
		1757	32.3.5 Notes on Stopping Clocks, description changed (6.5 ms → 5.5 ms)
		1764	Table 32.23 Pipe Settings, PIPEBUF.BUFNMB bit, Remark, area range changed (8 to 87 hex → 8 to 80 hex)
		1776	32.11.3.2 Interval Counter Initialization, section title changed
		33. Serial Communications Interface with FIFO (SCIFA)	
		1792	Table 33.4 Bit Rates and BRR Register Settings in Asynchronous Mode, Bit Rate, 110 bps deleted, 115200 bps and 500000 bps, settings for SERICLK changed (to blank), note changed
		1793	Table 33.6 Maximum Bit Rates for Various Frequencies with Baud Rate Generator (in Asynchronous Mode), Maximum Bit Rate, values changed, note changed
		1793	Table 33.8 Maximum Bit Rates with External Clock Input (in Asynchronous Mode), Maximum Bit Rate, values changed, note changed
		1794	Table 33.10 Bit Rates and BRR and MDDR Registers Settings in Asynchronous Mode, added
		1830	33.8.4 Break Signal Transmission, erroneous descriptions of bit name corrected (SPB2DT → SPB2IO)
		37. SPI Multi I/O Bus Controller (SPIBSC)	
		2145	37.2.1 Common Control Register (CMNCR), b24 (SFDE), value after reset changed
		41. ΔΣ Interface (DSMIF)	
		2275	Table 41.8, title name, “example” deleted and a complement “The Only Allowed Combinations of the Register Values” added
		2278	41.5.2 Current Value on Detection of an Overcurrent, added
		42. Error Control Module (ECM)	
		2338	42.3.1 Operations for Error Output, description changed, ERROROUT# Pin Output Level for Dynamic-mode in the table, changed
		46. RAM (Product Option)	
		2459	Table 46.1 Specifications of RAM, the item “Data retention function” deleted
		47. Electrical Characteristics (Target)	
		2478	Table 47.3 DC Characteristics (2) [Power Supply], Normal Operation, “TBD” cells filled with values, VDD type, values changed
		2530	Table 47.28 SPIBSC Timing, minimum values for tSU and tH changed
		2532	Figure 47.60, bit name included in the title changed (SPHAR → CPHAR)
		2533	Figure 47.63, bit name included in the title changed (SPHAR → CPHAR)
		2534	Table 47.29 RIICa Timing, symbols changed (tr → tsr, tf → tsf), note 4 added
		2539	Table 47.32 ETHERC Timing, expression of a symbol changed (Tr/Tf → Tr, Tf)
		2539	Figure 47.70 Timing with the CLKOUT25Mn and RMII Signals, changed
		2541	Figure 47.74 MII Transmission Timing (Normal Operation), changed (ETHn_CRS and ETHn_COL deleted)
		2541	Figure 47.75 MII Transmission Timing (Conflict Occurrence), changed (ETHn_CRS and ETHn_COL deleted)
		2543	Table 47.33 Serial Management Interface, ETHn_MDIO output delay time (to ETHn_MDC↑), the arrow direction changed from up to down, the minimum and maximum values for tDMDIO changed
		2543	Figure 47.78 Serial Management Access Timing, changed
		2548	Table 47.37 12-Bit A/D (Unit 0) Conversion Characteristics, “TBD” cells filled with values
		2549	Table 47.38 12-Bit A/D (Unit 1) Conversion Characteristics, “TBD” cells filled with values

Rev.	Date	Description	
		Page	Summary
0.90	Sep. 07, 2015	Appendix 1. Outer Dimensions Diagram	
		2554, 2555	Newly added
1.00	Feb. 15, 2016	All	Products incorporating an R-IN Engine → Products incorporating an R-IN Engine (optional), EtherCAT slave controller (optional), EtherCAT (optional), products incorporating an EtherCAT (optional)
		All	Module symbol changed (S12ADC → S12ADCa)
		All	Module symbol changed (GPTA → GPTa)
		Features	
		54	Note 4 added
		1. Overview	
		60	Table 1.1 Outline of Specifications, 12-bit A/D converter, conversion times are changed
		61	Table 1.1 Outline of Specifications, note 5 added
		62	Table 1.2 Comparison of Functions for Different Packages, description of EtherCAT slave controller (ECATC) changed
		65	Figure 1.1 Block Diagram, module name corrected (GPTA → GPTa)
		70	Table 1.4 Pin Functions, ETH2_RXD0 to 3 pins added, description for the PHYLINK0 and PHYLINK1 pins changed, descriptions for the PHYRESETOUT# and PHYRESETOUT2# pins changed, the CATRESTOUT pin deleted
		72	Table 1.4 Pin Functions, note 1 added
		73	Figure 1.2 Pin Arrangement (320-pin FBGA), name of A10 pin corrected
		5. I/O Register	
		179	Table 5.1 List of I/O Registers, address corrected (A007 20BCh → A007 20ACh)
		204	Table 5.1 List of I/O Registers, register symbol of the input learning blocking register corrected
		213	Table 5.1 List of I/O Registers, register name of BUFID changed (receive FIFO information register → receive buffer information register), Ether Switch 10-Mbps/half-duplex mode setting register (ETHSW10HDEN) added
		9. Low-Power Consumption Function	
		258	Bit name of b18 (MSTPCRB18), note 3 added
		261	9.2.5 Module Stop Control Register E (MSTPCRE), descriptions of b1 to b3 (reserved bits) changed
		10. Debugging Interface	
		277	Table 10.10 Available Trace Functions, module names are changed
		12. Interrupt Controller (ICUA)	
		289	12.2.6 NMI Pin Interrupt Control Register (NMICR), description for the register changed
		339	12.4.2.13 Interrupt Address Register (HVA0), description for the register changed
		365	Figure 12.6 Initializing Registers of VIC, content changed and a note added
		369	Figure 12.8 IRQ Interrupt Operation (Level Operations), register name changed (HVA → HVA0)
		370	Figure 12.9 IRQ Interrupt Operation (Edge Interrupt), register name changed (HVA → HVA0),
		372	Figure 12.10 Concept of Multiple Interrupts (1 / 2), descriptions changed
		373	Figure 12.10 Concept of Multiple Interrupts (2 / 2), descriptions added
		375	12.4.6.3 Notes on Selecting Level Detection, descriptions changed, an example program added
		14. Bus State Controller	
		476	Table 14.19 Number of Idle Cycles Inserted between Access Cycles to Different Memory Types, note 1, bit symbol corrected (HM → HW)
		15. DMA Controller (DMACAa)	
		479	Table 15.2 Pin Configuration of the DMAC, note, a section for reference added
		498	15.2.13 Channel Configuration Register n (CHCFG_n), bit table, b10 to b8, AM[2:0], description, a note added

Rev.	Date	Description	
		Page	Summary
1.00	Feb. 15, 2016	503	15.2.17 Source Continuous Register n (SCNT_n), description of the register changed (0000h → 0000 0000h)
		506	15.2.19 Destination Continuous Register n (DCNT_n), description of the register changed (0000h → 0000 0000h)
		509	15.2.21 DMA Control Register (DCTRL_X (X = A or B)), bit table, b31-b1 (reserved bits) changed
		533	Figure 15.13 Block Transfer Mode (REQD = 0, SDS = DDS), changed to internal signals, a note added
		546	15.3.5 DMA Acknowledge Output/DMA Transaction Completion Output Function, descriptions added
		547	Table 15.22 DACKn/TENDn Pin Output Settings, description of applications for the mask mode partially changed (low → inactive)
		561	Table 15.25 DMA Transfer Setting Example 1, the start address of transfer source changed, description of DAM transfer request changed, an item “selection of the side which makes a transfer requests” added
		561	15.5.1 Setting Example 1 (Register Hardware Request), Setting Example 1, values for N0SA and CHCFG, changed
		562	Figure 15.37 Setting Example 1, content changed
		16. Event Link Controller (ELC)	
		577	16.2.2 Event Link Setting Register n (ELSRn), n = 16 deleted
		579	Table 16.3 Correspondence between Event Signal Names Set in ELSRn.ELS[7:0] Bits and Signal Numbers, descriptions of Ethernet controller changed (limitation for the product is deleted, signals are denoted as optional)
		18. Multi-Function Pin Controller (MPC)	
		All	Package names corrected (320-pin BGA → 320-pin BGA, 176-pin QFP → 176-pin HLQFP)
		646	18.2.5 P3n Pin Function Control Register (P3nPFS), bit map, values after reset are changed, notes 1 and 2 are added
		20. Port Output Enable 3 (POE3)	
		937	Table 20.1 POE3 Specifications, Conditions for the high-impedance state, descriptions of MTU complementary PWM output pins changed
		21. General PWM Timer (GPTa)	
		1104	Table 21.10 Output Pins for Channels 0 to 2, specified ports are changed
		28. Ethernet MAC (ETHERC)	
		All	Descriptions changed (receive FIFO → receive buffer)
		1311	Table 28.2 Input/Output Pins of the ETHERC, pins ETH2_RXD0 to ETH2_RXD3 are added, descriptions for PHYLINK0 and PHYLINK1 are changed, descriptions for PHYRESETOUT# and PHYRESETOUT2# are changed
		1315	Table 28.3 MAC Function Selection Method for Products Incorporating EtherCAT (an Optional Function), contents changed
		1315	Table 28.4 MAC Function Selection Method, contents changed
		1317	28.2.1.6 Ethernet Peripheral Reset Register (ETHSFTRST), bit table, b2 (PHYRST), descriptions changed
		1318	28.2.2.1 MIIM Register (GMAC_MIIM), bit table, b26 (RWDV), write or read attribute changed
		1324	28.2.2.6 TX MODE Register (GMAC_TXMODE), b26 changed (SFOP → reserved bit)
		1333	28.2.2.13 TX FIFO Status Register (GMAC_TXFIFO), b31 changed (TFULL → reserved bit)
		1337	28.2.2.18 Receive Buffer Information Register (BUFID), descriptions of the register changed, the bit name, description and the write or read attribute of b31 (NOEP) in the bit table changed
		1344	28.3.1 Hardware Functions, a note added
		1345	Figure 28.4 Flow of Processing for Issuing the Hardware Function Call, contents changed
		1349	(e) List of Hardware Function Calls, a note added
		1353	Figure 28.9 Outline of Processing by the Reception MACDMAC, a register name corrected (BUFFID → BUFID)

Rev.	Date	Description	
		Page	Summary
1.00	Feb. 15, 2016	1376	28.3.4.6 Format of receive data, description of the register partially changed (a word boundary → a 64-bit boundary)
		1376	Figure 28.15, “for Frames without the TCP/IP and UDP/IP Packets” is added in the title name, the size of padding changed (0 to 3 → 0 to 7), a field name corrected (TOOSHOTR → TOOSHORT)
		1377	Figure 28.16 Format of Receive Data for Frames with the TPC/IP and UDP/IP Packets, newly added
		29. Ethernet Switch	
		All	Descriptions changed (receive FIFO → receive buffer)
		1385	29.2.1.1 Ethernet PHY LINK Mode Register (ETHPHYLNK), bit table, bit names of b0 (SWLINK0), b1 (SWLINK1), b2 (CATLINK0), and b3 (CATLINK1) are changed
		1388	29.2.1.4 Ether Switch 10-Mbps/Half-Duplex Mode Setting Register (ETHSW10HDEN), newly added
		1393	29.2.2.5 Input Learning Blocking Register, register symbol changed
		1416	29.2.4.3 FIFO BUffer Threshold Register n (Shared), descriptions for TX_SECTION_EMPTYn and TX_SECTION_FULLn partially corrected (receive FIFO → transmit FIFO)
		1447	29.2.6.12 DLR Beacon Interval Register (BEC_INTRVL), b31 to b0 (BECINTCAL), descriptions partially changed
		1449	29.2.6.15 DLR Beacon Timeout Timer Register (INV_TMOUT), b31 to b0 (INVBECTMOUT), descriptions partially changed
		30. EtherCAT Slave Controller (Only for Products Incorporating an R-IN Engine)	
		1503	30.6.1 Write Register Enable Register (WR_REG_ENABLE), b7 to b1 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1503	30.6.2 Write Register Protection Register (WR_REG_PROTECT), b7 to b1 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1504	30.6.3 ESC Write Enable Register (ESC_WR_ENABLE), b7 to b1 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1504	30.6.4 ESC Write Protection Register (ESC_WR_PROTECT), b7 to b1 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1506	30.7.2 ESC Reset PDI Register (ESC_RESET_PDI), b7 to b2 (reserved bits), descriptions partially deleted, write or read attribute for PDI changed
		1507, 1508	30.7.3 ESC DL Control Register (ESC_DL_CONTROL), b7 to b2 (reserved bits), b23 to b29, and b31 to b25, descriptions partially deleted, write or read attributes for ECAT changed
		1529	30.13.1 EEPROM Configuration Register (EEP_CONF), b7 to b2 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1530	30.13.3 EEPROM Control/Status Register (EEP_CONT_STAT), b6 (READBYTE) and b7 (PROMSIZE), write or read attributes for PDI and ECAT changed
		1533	30.14.2 PHY Address Register (PHY_ADR), b7 to b5 (reserved bits), write or read attributes for PDI and ECAT changed
		1533	30.14.3 PHY Register Address Register (PHY_REG_ADR), b7 to b5 (reserved bits), write or read attributes for PDI and ECAT changed
		1534	30.14.5 MII Management ECAT Access State Register (MII_ECAT_ACS_STAT), b7 to b1 (reserved bits), write or read attribute for ECAT changed
		1535	30.14.6 MII Management PDI Access State Register (MII_PDI_ACS_STAT), b7 to b2 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1538	30.15.3 FMMU Logical Start Bit m Register (FMMUm_L_START_BIT), b7 to b3 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1538	30.15.4 FMMU Logical Stop Bit m Register (FMMUm_L_STOP_BIT), b7 to b3 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1539	30.15.6 FMMU Physical Start Bit m Register (FMMUm_P_START_BIT), b7 to b3 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1540	30.15.7 FMMU Type m Register (FMMUm_TYPE), b7 to b2 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed

Rev.	Date	Description	
		Page	Summary
1.00	Feb. 15, 2016	1540	30.15.8 FMMU Activate m Register (FMMUm_ACT), b7 to b1 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1542	30.16.3 SyncManager Control m Register (SMm_CONTROL), b7 (reserved bit), write or read attribute for ECAT changed
		1544	30.16.5 SyncManager Activate m Register (SMm_ACT), b5 to b2 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1545	30.16.6 SyncManager PDI Control m Register (SMm_PDI_CONT), b7 to b2 (reserved bits), descriptions partially deleted, write or read attribute for PDI changed
		1548	30.17.2.2 Receive Time ECAT Processing Unit Register (DC_RCV_TIME_UNIT), values after reset are added to each bit table
		1554	30.17.3.1 Cyclic Unit Control Register (DC_CYC_CONT), b3 to b1 (reserved bits) and b7, b6 (reserved bits), descriptions partially deleted, write or read attribute for ECAT changed
		1557	30.17.4.4 SYNC0 Status Register (DC_SYNC0_STAT), b7 to b1 (reserved bits), write or read attribute for PDI changed
		1557	30.17.4.5 SYNC1 Status Register (DC_SYNC1_STAT), b7 to b1 (reserved bits), write or read attribute for PDI changed
		1561	30.17.5.1 Latch 0 Control Register (DC_LATCH0_CONT), b7 to b2 (reserved bits), write or read attribute for ECAT changed
		1561	30.17.5.2 Latch 1 Control Register (DC_LATCH1_CONT), b7 to b2 (reserved bits), write or read attribute for ECAT changed
		31. USB2.0HS Host Module (USBh)	
		1611	31.3.2.5 USBCMD Register, b4 Periodic Schedule Enable, a note added
		1633	31.3.3.12 Offset E0h Register (EXT1), b12 changed (reserved → PSD),
		33. Serial Communications Interface with FIFO (SCIFA)	
		1802	33.2.12 Serial Port Register (SPTR), descriptions of the register partially deleted, a note added
		1814	Figure 33.4 Sample Flowchart for Transmitting Serial Data in Asynchronous Mode, a note added
		1832	33.8.4 Writing to the SPTR Register, newly added
		35. CAN Interface (RSCAN)	
		1912	Table 35.1 Specifications of the RSCAN, Tq in the item Communication speed changed
		1919	35.2.2 Channel Control Registers (RSCAN0CmCTR), the RTBO bit, descriptions partially changed (1 CAN bit time → One CANm bit time)
		1928	35.2.5 Global Configuration Register (RSCAN0GCFG), the DCS bit, descriptions partially changed, Table 35.4 Range of Operating Frequency Depending on the Transfer Rate and the Number of Channels in Use, deleted
		1943	35.2.17 Receive Buffer Number Register (RSCAN0RMNB), b7 to b0 (NRXMB[7:0]), descriptions partially changed
		2014	Table 35.14 Global Mode Transition Time, descriptions partially changed (CAN frame → CANm frame)
		2017	Table 35.15 Channel Mode Transition Time, descriptions partially changed (CANm frame → CANm frame (one message))
		2035	Figure 35.16 CAN Setting Procedure after the MCU is Reset, bit names are changed (GSLPR → GMDC, CSLPR → GHMDC), the register RSCAN0GAFLCFG1 deleted
		2037	Table 35.22 Example of Bit Timing Setting, 12 Tq, 24 Tq, and 25 Tq are added
		2038	Table 35.23 Example of Communication Speed Setting, frequencies changed (40 MHz, 16 MHz, and 8 MHz are deleted, 32 MHz was changed to 25 MHz)
		2041	Figure 35.21 Buffer Setting Procedure, the number of the receive buffers changed (0 to 31 → 0 to 32)
		36. Serial Peripheral Interface (RSPIa),	
		2074	36.2.5 RSPI Data Register (SPDR), bit map for the 16 higher-order bits added
		40. Boundary Scan	
		2230 to 2236	Table 40.5 Boundary Scan Register, package name corrected (320BGA → 320 FBGA)

Rev.	Date	Description	
		Page	Summary
1.00	Feb. 15, 2016	41. ΔΣ Interface (DSMIF)	
		2270	41.2.30 Channel X Current Value Register 2 (X2DATA), the addresses are changed
		42. Error Control Module (ECM)	
		2286	42.2.2 ECM Master/Checker Error Clear Trigger Register (ECMmECLR (m = M or C)), the register symbol in the description corrected (ECMmEST → ECMmECT)
		43. 12-Bit A/D Converter (S12ADCa)	
		2345	Table 43.1 Specifications of 12-Bit A/D Converter, conversion time changed
		2346	Table 43.1 Specifications of 12-Bit A/D Converter, numbering of notes are changed
		2446	43.5.11 Allowable Signal Source Impedance, deleted
		46. RAM (Product Option)	
		2463	46.2.3 ECC Decoder Configuration Register (RAMEDC) (for Products Incorporating an R-IN Engine), descriptions partially changed (... for instruction RAM is enabled → ... for instruction RAM and data RAM are enabled)
		47. Electrical Characteristics	
		2477	Table 47.1 Absolute Maximum Rating, note 4 added
		2478	Figure 47.1 Power On/Off Sequence, notes 1 and 3 are changed
		2479	47.3 DC Characteristics, conditions are changed
		2479	Table 47.3 DC Characteristics (2) [Power Supply], Normal operation, values for VIcc changed, Standby mode with all modules inactive (reference value), units for the typical values of AV0Icc, AV1Icc, VRF0Icc, VRF1Ivcc are changed
		2483	47.4 AC Characteristics, conditions are changed
		2540	Table 47.32 ETHERC Timing, ETHERC (RMII), descriptions partially changed (ETHn_Txxx, ETHn_Rxxx, ETHn_Rxxx), values are added in T.B.D cells, ETHERC (MII), ETHn_TXER output delay time (tTERd) is added, note 1 changed
		2542	Figure 47.74 MII Transmission Timing, changed
		2542	Figure 47.75 MII Transmission Timing, changed
		2547	47.5 USB Characteristics, conditions are added
		2549	47.6 A/D Conversion Characteristics, conditions are added
		2551	47.7 Temperature Sensor Characteristics, conditions are added
		2554	Figure 47.90 Trace Interface Timing, changed
1.10	May 31, 2016	Feature	
		54	A feature added (maximum operating frequency of 300 MHz with 498 DMIPS)
		1. Overview	
		55	Table 1.1 Outline of Specifications, Cortex-R4F: Maximum operation frequency (320-pin FBGA) changed
		55	Table 1.1 Outline of Specifications, Clock generation circuit: CPU clock is modified
		56	Table 1.1 Outline of Specifications, VIC: Sources for peripheral function interrupts changed
		56	Table 1.1 Outline of Specifications, General-purpose I/O ports: Open-drain outputs for 320-pin FBGA and 176-pin HLQFP deleted
		57	Table 1.1 Outline of Specifications TPUa: Description for PWM output mode changed, Number of channels for cascaded-connected operation changed
		64	Table 1.3 List of Products: Four products are added
		66	Table 1.4 Pin Functions (1 / 7), Debug interface: Descriptions for TRST#, TMS, TDI, TDO, and TCK changed
		72	Table 1.4 Pin Functions (7 / 7), I/O ports (P30 to P37, PC0 to PC7): Input/output attribute and description changed
		73	Figure 1.2 Pin Arrangement (320-Pin FBGA) (Top View): Title changed
		74	Figure 1.3 Pin Arrangement (176-pin HLQFP), Pin numbers 35 and 37: Pin names changed
		83	Table 1.6 Pin Assignments (176-Pin HLQFP) (1 / 4), Pin numbers 35 and 37: Pin names changed

Rev.	Date	Description	
		Page	Summary
1.10	May 31, 2016	90	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (4 / 10), F6: Newly added
		94	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (8 / 10) T13, T15, T16, T18: Newly added
		95	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (9 / 10) V14: Newly added
		4. Address Space	
		125	Figure 4.2 Memory Map (1-Mbyte Extended Internal SRAM): Note 1 added
		126	Figure 4.3 Memory Map (0-Kbyte Extended Internal SRAM): Note 4 deleted, statement “mirror area of” added
		126	Figure 4.3 Memory Map (0-Kbyte Extended Internal SRAM): Note 1 changed, Note 4 and 5 deleted (Note 6 moved up to Note 4)
		5. I/O Registers	
		179	Table 5.1 List of I/O Registers (Address Order) (52 / 86), XYZ overcurrent abnormality detection lower limit setting register (XYZIUNCMP) and XYZ overcurrent abnormality detection upper limit setting register (XYZIOVCMP): Addresses changed
		7. Clock Generation Circuit	
		227	7.2.1 System Clock Control Register (SCKCR), Bit table, b15, b14 (ETCKD[1:0]): Description for the value 11 changed
		232	7.2.4 PLL1 Control Register (PLL1CR), Bit table: Note 1 added (Previous note moved down to Note 2)
		9. Low-Power Consumption Function	
		254	Table 9.2 Stopping Peripheral Modules and Exiting Module-Stop State (2/ 2): Encoder interface added, Note 3 changed
		261	9.2.5 Module Stop Control Register E (MSTPCRE), Bit map and bit table: b0 (MSTPCRE0) added
		12. Interrupt Controller (ICUA)	
		375	12.4.6.2 Notes on Accessing HVA0 Register: Descriptions changed, program example and note added
		15. DMA Controller (DMACAa)	
		509	Figure 15.2 Relationship between DSKP and DCNT: Title changed
		552	Table 15.26 DMA Transfer Setting Example 2: Transfer source start address changed
		563	15.5.2 Setting Example 2 (Register Mode Software Request): N1SA transfer source address changed
		564	Figure 15.38 Setting Example 2: Addresses changed
		565	Table 15.27 DMA Transfer Setting Example 3: Transfer source start address changed
		565	15.5.3 Setting Example 3 (Register Mode Continuous Execution): Addresses of N0DA (transfer destination), N1SA (transfer source), and N1DA (transfer destination) changed
		566	Figure 15.39 Setting Example 3: Addresses changed
		568	Table 15.30 DMA Transfer Setting Example 4 (Descriptor 2): Transfer source start address changed
		568	Table 15.31 DMA Transfer Setting Example 4 (Descriptor 3): Transfer source/destination start addresses changed
		569	Table 15.32 Descriptor Settings, SA: Addresses for descriptor 1 and 3 changed, DA: Address for descriptor 3 changed
		17. I/O Ports	
		608	Figure 17.2 I/O Port Configuration (2), Note 1 changed
		609	Figure 17.2 I/O Port Configuration (3), Note 1 changed
		610	Figure 17.2 I/O Port Configuration (4), Note 1 changed
		611	Figure 17.2 I/O Port Configuration (5), Note 1 changed
		612	Table 17.3 Handling of Unused Pins: RES# and Port 33 (TDO) deleted
		18. Multi-Function Pin Controller (MPC)	
		646	18.2.5 P3n Pin Function Control Register (P3nPFS) (n = 0 to 7): Descriptions changed

Rev.	Date	Description	
		Page	Summary
1.10	May 31, 2016	646	18.2.5 P3n Pin Function Control Register (P3nPFS) (n = 0 to 7): Description for ISEL changed
		19. Multi-Function Timer Pulse Unit (MTU3a)	
		905	Table 19.81 Output Pins for Channels 6 and 7, Note for Port group 1 changed, Note 3 changed
		20. Port Output Enable 3 (POE3)	
		969	Table 20.5 Correspondence between MTU and GPT Pins: Note 2 added
		28. Ethernet MAC (ETHERC)	
		1342	28.2.3.4 Hardware Function Return Value Register (R0, R1): Descriptions changed
		1342	28.2.3.4 Hardware Function Return Value Register (R0, R1), R0 bit table: b31 to b0 (R0B[31:0]), descriptions changed
		1342	28.2.3.4 Hardware Function Return Value Register (R0, R1), R1 bit table; b31 to b0 (R1B[31:0]), descriptions changed
		1346	Figure 28.4 Flow of Processing for Issuing the Hardware Function Call: Note 1 added
		29. Ethernet Switch	
		1386	29.2.1.1 Ethernet PHY LINK Mode Register (ETHPHYLNK), Bit table, b2 (CATLINK0) and b3 (CATLINK1): Erroneous description for value 1 corrected
		1389	29.2.1.4 Ether Switch 10-Mbps/Half-Duplex Mode Setting Register (ETHSW10HDEN), Bit map, b1 and b0: Value after reset changed
		1394	29.2.2.5 Input Learning Blocking Register (INPUT_LEARN_BLOCK): Erroneous register symbol corrected (LERAN → LEARN)
		31. USB2.0HS Host Module (USBh)	
		1683	Figure 31.13 Initial Setting Sequence: Terms changed (CPG → Clock)
		32. USB 2.0 HS Function Module (USBf)	
		1760	Figure 32.4 Startup Sequence: Terms changed (CPG → Clock)
		34. I2C Bus Interface (RIICa)	
		1837	Figure 34.1 RIIC Block Diagram, FMPE deleted
		1839	34.2.1 I2C Bus Control Register 1 (ICCR1): Index n added
		1879	34.3.5 Slave Transmit Operation: Steps (2) and (6) changed (ICSR1.HOA deleted)
		1882	34.3.6 Slave Receive Operation: Steps (2) and (5) changed (ICSR1.HOA deleted)
		35. CAN Interface (RSCAN)	
		1912	Table 35.1 Specifications of the RSCAN (1 / 2), Communication speed: Definition of Tq changed
		37. SPI Multi I/O Bus Controller (SPIBSC)	
		2148	37.2.1 Common Control Register (CMNCR), Bit table: Bit names of b17, b16 (MOIIO0[1:0]), b19, b18 (MOIIO1[1:0]), b21, b20 (MOIIO2[1:0]), and b23, b22 (MOIIO3[1:0]) changed
		2158	37.2.7 Data Read Option Setting Register (DROPR), Bit map: Bit symbol of b7 to b0 changed
		41. ΔΣ Interface (DSMIF)	
		2264	41.2.22 XYZ Status Register (XYZSTA), Bit map: b8 and b0 changed, Bit table: b0, b7, b8, and b9 changed
		2265	41.2.23 XYZ Overcurrent Abnormality Detection Lower Limit Setting Register (XYZIUNCMP): Address changed
		2266	41.2.24 XYZ Overcurrent Abnormality Detection Upper Limit Setting Register (XYZIOVCMP): Address changed
		2279	41.3.6 Setting Examples: Descriptions changed
		2279	Figure 41.9: Title changed, flows changed, Note 1 added
		2280	Figure 41.10 Operation when MCLKn is not Inverted: Terms changed (CPG → Clock generation circuit)
		2280	Figure 41.11 Operation when MCLKn is Inverted: Terms changed (CPG → Clock generation circuit)
		2281	41.5.1 Initial Settings for Error Sources after Release from the Module-Stop State: Descriptions changed, Note 1 changed

Rev.	Date	Description	
		Page	Summary
1.10	May 31, 2016	42. Error Control Module (ECM)	
		2286	Table 42.2 ECM Error Input (1 / 2), Error source numbers 29 and 30: Functions changed
		2288	42.2.3 ECM Master/Checker Error Source Status Register 0 (ECMmESSTR0 (m = M or C)), Bit map: b29 and b28 changed
		2288	42.2.3 ECM Master/Checker Error Source Status Register 0 (ECMmESSTR0 (m = M or C)), Bit table: b28 and b29 changed
		2294	42.2.8 ECM Maskable Interrupt Configuration Register 0 (ECMMICFG0), Bit map: b29 and b28 changed, Bit table: b28 and b29 changed, Bit names of b30 and b31 changed
		2299	42.2.11 ECM Non-maskable Interrupt Configuration Register 0 (ECMNMICFG0), Bit map: b29 and b28 changed
		2301	42.2.11 ECM Non-maskable Interrupt Configuration Register 0 (ECMNMICFG0), Bit table: b29 and b28 changed
		2304	42.2.14 ECM Internal Reset Configuration Register 0 (ECMIRCFG0), Bit map: b29 and b28 changed, Bit table: b28 and b29 changed, Bit name of b31 changed
		2309	42.2.17 ECM Error Mask Register 0 (ECMEMK0), Bit map: b29 changed
		2311	42.2.17 ECM Error Mask Register 0 (ECMEMK0), Bit table: b28 and b29 changed
		2314	42.2.20 ECM Error Source Status Clear Trigger Register 0 (ECMESSTC0), Bit map: b29 and b28 changed
		2316	42.2.20 ECM Error Source Status Clear Trigger Register 0 (ECMESSTC0), Bit table: b28 and b29 changed
		2319	42.2.24 ECM Protection Status Register (ECMPS), Bit table: R/W for b0 (ECMPRERR) changed, descriptions and R/W for b7 to b1 (reserved bits) changed
		2320	42.2.25 ECM Pseudo Error Trigger Register 0 (ECMPE0), Bit map: b29 and b28 changed
		2322	42.2.25 ECM Pseudo Error Trigger Register 0 (ECMPE0), Bit table: b28 and b29 changed
		2327	42.2.31 ECM Delay Timer Configuration Register 0 (ECMDTMCFG0), Bit map: b29 and b28 changed
		2329	42.2.31 ECM Delay Timer Configuration Register 0 (ECMDTMCFG0), Bit table: b28 and b29 changed
		2333	42.2.34 ECM Delay Timer Configuration Register 3 (ECMDTMCFG3), Bit map: b29 and b28 changed
		2335	42.2.34 ECM Delay Timer Configuration Register 3 (ECMDTMCFG3), Bit table: b28 and b29 changed
		2342	42.3.4.1 Protection Unlock Sequence, Description 1 changed
		43. 12-Bit A/D Converter (S12ADCa)	
		2346	Table 43.1 Specifications of 12-Bit A/D Converter (1 / 2): Descriptions changed (term CPG deleted)
		2446	43.5.12 Allowable Signal Source Impedance added
		44. Temperature Sensor	
		2451	Figure 44.2 Procedure for Using the Temperature Sensor: Content changed
		47. Electrical Characteristics	
		2477	Table 47.1 Absolute Maximum Rating: Note 5 added
		2480	Table 47.3 DC Characteristics (2) [Power Supply], Normal operation: VDD changed
		2485	Table 47.10 Operating Frequency, CPU clock (CPUCLK): Values for 320-pin FBGA changed, Note 1 added
		2556	Figure 47.90: Trance Interface Timing: Symbol corrected from RACECTR to TRACECTL
1.20	Mar. 02, 2017	1. Overview	
		62	Table 1.2 Comparison of Functions for Different Packages: Functions of ETHERC and ECATC, modified. Note 1 added.
		65	Figure 1.1 Block Diagram: Functional blocks of ECATC and ETHERC, modified. Note 1 modified.
		73	Figure 1.2 Pin Arrangement (320-Pin FBGA) (Top View): Pin ERROROUT#, modified

Rev.	Date	Description	
		Page	Summary
1.20	Mar. 02, 2017	3. Operating Modes	
		113	Table 3.3 Parameter Information for the Loader in 16-bit or 32-bit Bus Boot Mode: Reference of Note 2, modified
		114	Table 3.4 Parameter Information for the Loader in SPI Boot Mode: Reference of Note 2, modified
		116	3.5.4.1 Operation Settings in SPI Boot Mode: Operation settings, added
		123	3.5.8.2 Serial Flash Memory in SPI Boot Mode, added
		9. Low-Power Consumption Function	
		259	9.2.2 Module Stop Control Register B (MSTPCRB): Notes 1 and 3 for the table of bits were modified.
		10. Debugging Interface	
		266	Figure 10.1 Block Diagram of CoreSight: Reference modified
		277	Figure 10.8 Example of Connection Circuit of an Emulator That Can Drive the nTRST Output to High: Waveforms when the emulator is not connected and when the emulator is connected, modified
		12. Interrupt Controller (ICUA)	
		288	12.2.4 Non-maskable Interrupt Status Register (NMISR), Description on the NMIST flag: [Setting condition] modified
		302	12.3.4 NMI Pin Interrupts: Description modified
		347	12.4.2.15 Interrupt Service Current Register n (ISCn) (n = 0 to 9), ISC1, Description on the ISCi bit: Suffix (n) modified
		348	12.4.2.15 Interrupt Service Current Register n (ISCn) (n = 0 to 9), ISC3, Description on the ISCi bit: Suffix (n) modified
		349	12.4.2.15 Interrupt Service Current Register n (ISCn) (n = 0 to 9), ISC5, Description on the ISCi bit: Suffix (n) modified
		350	12.4.2.15 Interrupt Service Current Register n (ISCn) (n = 0 to 9), ISC7, Description on the ISCi bit: Suffix (n) modified
		351	12.4.2.15 Interrupt Service Current Register n (ISCn) (n = 0 to 9), ISC9, Description on the ISCi bit: Suffix (n) modified
		352	12.4.2.16 Interrupt Address Store Register 0 (VADn) (n = 1 to 255) Interrupt Address Store Register 1 (VADn) (n = 256 to 300): Suffix modified (n → i)
		357	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table (2 / 9): Vector number 50: Source of ETHPHYI2, modified
		365	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table: Note 4. added
		368	Figure 12.8 Register Rewrite Flow, modified
		377	12.4.6.5 Using Falling-Edge Detection with the NMI Pin, added
		16. Event Link Controller (ELC)	
		579	Table 16.2 Correspondence between the ELSRn Register and the Peripheral Functions: ELSR16, Encoder I/F trigger 0 (optional) and ELSR28, Encoder I/F trigger 1 (optional), added
		580	Table 16.3 Correspondence between Event Signal Names Set in ELSRn.ELS[7:0] Bits and Signal Numbers (1 / 3): Encoder I/F, added
		597	Table 16.5 Operations of Modules When Event is Input: Encoder I/F, added
		17. I/O Ports	
		619	Table 17.3 Handling of Unused Pins: Handling of the TRST# and TCK pins, modified
		18. Multi-Function Pin Controller (MPC)	
		635	Table 18.1 List of Multiplexed Pin Configurations (16 / 21): PHYRESETOUT# was moved to the Ethernet controller (Ether0) section.
		20. Port Output Enable 3 (POE3)	
		937	Table 20.1 POE3 Specifications, Conditions for the high-impedance state: MTU complementary PWM output pins, modified
		971	Figure 20.4 Low-Level Detection Operation: PCLKB clocks, modified

Rev.	Date	Description	
		Page	Summary
1.20	Mar. 02, 2017	21. General PWM Timer (GPTa)	
		1101	21.7.4 Output Protection Function for GTIOC Pin Output, (4) Restricted Specification of Output Protection Function: Description modified
		1103	21.9.2 Settings of GTCCRn during Compare Match Operation (n = A, B, C, D, E, F), (1) When automatic dead time setting has been made in triangle-wave PWM mode: Description modified
		24. Compare Match Timer (CMT)	
		1228	24.2.4 Compare Match Timer Control Register (CMCR): b7 (reserved bit) was added to the table of bits.
		28. Ethernet MAC (ETHERC)	
		1319	28.2.2.1 MIIM Register (GMAC_MIIM): Functional description on the RWDV bit, modified
		1320	28.2.2.3 TX RESULT Register (GMAC_TXRESULT): Description modified
		1322	28.2.2.5 RX MODE Register (GMAC_RXMODE): Register description modified. Functional description on the RX FIFO Read Trigger Threshold, Receive Almost Full Threshold, and Receive Almost Empty Threshold bits in the table of bits, modified.
		1325	28.2.2.6 TX MODE Register (GMAC_TXMODE): Register description modified. Functional description on the Transmit Almost Full Threshold and Transmit Almost Empty Threshold bits in the table of bits, modified. Note 1 added.
		1326	28.2.2.7 RESET Register (GMAC_RESET): Functional description modified
		1329	28.2.2.9 RX FLOW CONTROL Register (GMAC_FLWCTL): Register description modified
		1329	28.2.2.10 PAUSE Packet Register (GMAC_PAUSPKT): Register description modified
		1332	28.2.2.12 RX FIFO Status Register (GMAC_RXFIFO): Functional description on the RX FIFO Read Trigger bit in the table of bits, modified
		1333	28.2.2.13 TX FIFO Status Register (GMAC_TXFIFO): The TFULL bit was added to the bit chart and the table of bits.
		1334	28.2.2.14 TCPIPACC Register (GMAC_ACC): Functional description on the RX TCPIP accelerator enable bit in the table of bits, modified
		1335	28.2.2.16 LPI Mode Control Register (GMAC_LPI_MODE): Register description modified
		1337	28.2.2.18 Receive Buffer Information Register (BUFID): Register description modified
		1338	28.2.3.1 Hardware Function System Call Register (SYSC): Functional description on the SYSC[15:0] bits in the table of bits, modified. 5104h and 5114h, deleted.
		1344	Figure 28.3 Schematic Block Diagram of the Hardware Functions, modified
		1345	28.3.1.1 Initial Settings, Procedure for setting up the hardware functions: <3> modified, <4> added
		1347	28.3.1.3 Buffer Allocator, (1) Functional Overview: Description modified
		1350	28.3.1.3 Buffer Allocator, (2) Buffer Control Operation, (e) List of Hardware Function Calls: Description modified
		1354	Table 28.9 HWFNC_Buffer_Return: Function of R0[2:0] in return value registers, modified
		1354	28.3.1.4 MAC DMA Controller, (2) DMA for the reception MAC: Description modified
		1354	Figure 28.9 Outline of Processing by the Reception MACDMAC: Names of interrupts, modified
		1355	28.3.1.4 MAC DMA Controller, (2) DMA for the reception MAC, (a) Description of the individual functions of the MAC DMA controller: (2) description in 1-2) Full release of the buffer, modified
		1355	28.3.1.4 MAC DMA Controller, (2) DMA for the reception MAC, (a) Description of the individual functions of the MAC DMA controller: Description in 1-5) Judging whether a received frame is valid or invalid, modified
		1356	Figure 28.10 Conceptual Diagram of Judging Whether a Received Frame is Valid or Invalid, modified
		1360	Table 28.13 HWFNC_MACDMA_RX_Errstat: Function of R0[3:0] in return value registers, modified
		1363	Table 28.14 HWFNC_MACDMA_TX_Start: Functional description modified
		1364	28.3.1.5 Buffer RAM DMA Controller, (2) DMA transfer (a) Transfer between the buffer RAM and the data RAM: Description modified (b) Replacing data in the buffer RAM or data RAM: Description modified

Rev.	Date	Description	
		Page	Summary
1.20	Mar. 02, 2017	—	28.3.1.5 Buffer RAM DMA Controller, (2) DMA transfer (c) Transfer from the buffer RAM to the buffer RAM, deleted
		—	Table 28.18 HWFNC_INTBUFF_DMA_Start, deleted
		—	Table 28.19 HWFNC_INTBUFF_DMA_Start (Descriptor), deleted
		1370	Figure 28.13 Format of Transmit Data: Modified, Note 2 deleted.
		1371	Figure 28.14 Transmission Frame Control Information, added
		1371	28.3.3.2 Creating transmit data, (1) Transmission frame control information: Description of ICRC in the table, modified. Contents description, modified.
		1372	28.3.3.2 Creating transmit data, (2) Ethernet frame Type/Length: Length added, description modified VLAN Tag, VLAN Info: Added
		1372	28.3.3.2 Creating transmit data, (2) Ethernet frame, (a) When the transmission TCPIP accelerator is enabled: Added
		1373	28.3.3.2 Creating transmit data, (2) Ethernet frame, (b) When the transmission TCPIP accelerator is disabled: Added
		1375	28.3.3.5 Completing transmission: Description modified
		1377	Figure 28.20 Format of Received Data, modified
		—	Figure 28.16 Format of Receive Data for Frames with the TPC/IP and UDP/IP Packets, deleted
		1378	Figure 28.21 Reception Frame Information, added
		1378	28.3.4.6 Format of receive data, (1) Reception frame information: FIFOFULL was modified to FIFOOVF in the table. Description on IPV6NG, OUT_OF_LIST, VTAG, and FIFOOVF was modified. Note 1, added.
		1380	28.3.4.6 Format of receive data, (2) Ethernet frame Type/Length: Length added, description modified VLAN Tag, VLAN Info: Added FCS: Description modified
		1380	Figure 28.22 Destination MAC Address Field when Insertion of Management Tags is Permitted, modified
		1380	28.3.4.6 Format of receive data, (2) Ethernet frame, (a) If insertion of management tags is permitted: Note added
		1381	28.3.4.6 Format of receive data, (2) Ethernet frame, (b) When the reception TCPIP accelerator is enabled and TCP/UDP packet data is not included: Added
		1382	28.3.4.6 Format of receive data, (2) Ethernet frame, (c) When the reception TCPIP accelerator is enabled and TCP/UDP packet data is included: Added
		1383	28.3.4.6 Format of receive data, (2) Ethernet frame, (d) When the reception TCPIP accelerator is disabled: Added
		1384	28.3.5 TCPIP Accelerator, added
		1384	28.3.5.1 Transmission with Use of the TCPIP Accelerator, added
		1385	28.3.5.2 Reception with Use of the TCPIP Accelerator, added
		1387	28.4.1 Padding added to the MAC header in the transmit frame: Description modified
		1387	28.4.2 Misjudgment of the Result of Checksum Calculation by Hardware in Reception, added
		1387	28.4.3 Setting of the Module Stop Function Description modified: MSTPCRB.MSTPCRB14 to MSTPCRB17 → MSTPCRB.MSTPCRB16 to MSTPCRB19
		29. Ethernet Switch	
		1396	29.2.2.2 Unicast Default Mask Register (UCAST_DEFAULT_MASK): Functional description on the P0UCASTDM, P1UCASTDM, and P2UCASTDM bits, modified
		1397	29.2.2.3 Broadcast Default Mask Register (BCAST_DEFAULT_MASK): Functional description on the P0BCASTDM, P1BCASTDM, and P2BCASTDM bits, modified
		1398	29.2.2.4 Multicast Default Mask Register (MCAST_DEFAULT_MASK): Functional description on the P0MCASTDM, P1MCASTDM, and P2MCASTDM bits, modified

Rev.	Date	Description	
		Page	Summary
1.20	Mar. 02, 2017	1482	29.3.4.3 Adjustable Timer Module, (1) Overview: Description modified (nanosecond-timer reaches: 109 → 10^9)
		1495	29.4.4 Setting of Module Stop Function: Description modified
		30. EtherCAT Slave Controller (optional)	
		1578	30.18.5 Setting the Module-Stop Function: Description modified
		1578	30.19 Initial Settings, added
		33. Serial Communications Interface with FIFO (SCIFA)	
		1821	Figure 33.5 Example of Transmit Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected), modified (ICU.IRn → ICU.RAISn)
		1824	Figure 33.9 Example of SCIFA Receive Operation in Asynchronous Mode (8-Bit Data with Parity and One Stop Bit when LSB-First Transfer is Selected), modified (ICU.IRn → ICU.RAISn)
		1829	Figure 33.14 Example of SCIFA Transmit Operation in Clock Synchronous Mode (when LSB-First Transfer is Selected), modified (ICU.IRn → ICU.RAISn)
		1831	Figure 33.16 Example of SCIFA Receive Operation (when LSB-First Transfer is Selected), modified (ICU.IRn → ICU.RAISn)
		34. I^2C Bus Interface (RIICa)	
		—	34.12.1 Buffer Operation for TXI and RXI Interrupts, deleted
		—	34.15.2 Notes on Starting Transfer, deleted
		36. Serial Peripheral Interface (RSPIa)	
		2080	36.2.5 RSPI Data Register (SPDR): Bit chart of the SPDR register when accessing in words (the SPLW bit is 0), modified (b31 to b16 → b15 to b0)
		37. SPI Multi I/O Bus Controller (SPIBSC)	
		2154, 2155	37.2.1 Common Control Register (CMNCR): Description on the IO0FV[1:0], IO2FV[1:0], IO3FV[1:0], MOIIO0[1:0], MOIIO1[1:0], MOIIO2[1:0], and MOIIO3[1:0] bits in the table of bits, modified
		2171	37.2.14 SPI Mode Read Data Register 0 (SMRDR0): Register description, modified
		2171	37.2.15 SPI Mode Write Data Register 0 (SMWDR0): Register description, modified
		2177	Figure 37.4 Data Alignment in External Address Space Read Mode, modified
		2177	Figure 37.5 Data Alignment in SPI Operating Mode, modified
		40. Boundary Scan	
		2235	40.2.4 Boundary Scan Register (JTBSR): Description modified
		2236 to 2242	Table 40.5 Boundary Scan Register (320FBGA), modified
		2243 to 2246	Table 40.6 Boundary Scan Register (176QFP), added
		2250	40.4 Usage Notes: Notes no. 6, 8, 12, and 16 were added
		42. Error Control Module (ECM)	
		2293	Table 42.2 ECM Error Input (1 / 2): Functions of error source numbers 5 and 6, modified
		2295	42.2.1 ECM Master/Checker Error Set Trigger Register (ECMmESET (m = M or C)): Error of bit names in Notes 2 and 6, modified (ECMIE228 bit →ECMMIE228 bit)
		2297	42.2.3 ECM Master/Checker Error Source Status Register 0 (ECMmESSTR0 (m = M or C)): Description of bits ECMmSSE004 and ECMmSSE005, modified
		2303	42.2.8 ECM Maskable Interrupt Configuration Register 0 (ECMMICFG0): Description of bits ECMMIE004 and ECMMIE005, modified
		2308	42.2.11 ECM Non-maskable Interrupt Configuration Register 0 (ECMNMICFG0): Description of bits ECMNMIE004 and ECMNMIE005, modified
		2313	42.2.14 ECM Internal Reset Configuration Register 0 (ECMIRCFG0): Description of bits ECMIRE004 and ECMIRE005, modified
		2318	42.2.17 ECM Error Mask Register 0 (ECMEMK0): Description of bits ECMEMK004 and ECMEMK005, modified

Rev.	Date	Description	
		Page	Summary
1.20	Mar. 02, 2017	2323	42.2.20 ECM Error Source Status Clear Trigger Register 0 (ECMESSTC0): Description of bits ECMCLSSE004 and ECMCLSSE005, modified
		2328	42.2.23 ECM Protection Command Register (ECMPCMD1): Symbol of b7 to b0 in the table of bits, modified (ECM1REG7 to ECM1REG0 →ECM1REG[7:0])
		2329	42.2.25 ECM Pseudo Error Trigger Register 0 (ECMPE0): Description of bits ECMPE004 and ECMPE005, modified
		2336	42.2.31 ECM Delay Timer Configuration Register 0 (ECMDTMCFG0): Description of bits ECMTE004 and ECMTE005, modified
		2342	42.2.34 ECM Delay Timer Configuration Register 3 (ECMDTMCFG3): Description of bits ECMTE304 and ECMTE305, modified
		43. 12-Bit A/D Converter (S12ADCa)	
		2455	Table 43.13 Analog Pin Specifications: Note added
		46. RAM (Product Option)	
		2469	Table 46.1 Specifications of RAM: Description on the error checking, modified
		2470	46.2.1 Protect Command Register (RAMPCMD): Description on step 2, modified
		47. Electrical Characteristics	
		2490	Table 47.3 DC Characteristics (2) [Power Supply] Test conditions, modified: Product part no. added
		2491	Table 47.4 DC Characteristics (3) [Except for USB2.0 Host/Function-Related Pins] Item modified: "Input pull-up MOS current and resistance" and "Input pull-down MOS current and resistance" R_{pu1}, R_{pu2}, R_{pd1}, and R_{pd2} were added. Test conditions for "Input pull-down MOS current and resistance" were modified.
		2494	Table 47.10 Operating Frequency: Notes 1 to 3, added. The max. value of the CPU clock (CPUCLK), modified.
1.30	Apr. 25, 2017	1. Overview	
		102	Table 1.8 List of Pin and Pin Functions (176-Pin HLQFP) (6/6): The communication function of pin 171, modified
		3. Operating Modes	
		109	3.1 Overview: The description, modified
		5. I/O Registers	
		155	Table 5.1 List of I/O Registers (Address Order) (26/86): DCP configuration register (DCPCFG), deleted
		9. Low-Power Consumption Function	
		258	9.2.1 Module Stop Control Register A (MSTPCRA): The description, added
		259	9.2.2 Module Stop Control Register B (MSTPCRB): The description, added
		261	9.2.3 Module Stop Control Register C (MSTPCRC): The description, added
		262	9.2.4 Module Stop Control Register D (MSTPCRD): The description, added
		263	9.2.5 Module Stop Control Register E (MSTPCRE): The description, added
		263	9.2.6 Module Stop Control Register F (MSTPCRF): The description, added
		264, 265	9.3.1 Module-Stop Function: The description (procedure, description of procedures, table 9.3), added
		12. Interrupt Controller (ICUA)	
		365	Table 12.3 Cortex-R4F/DMAC Interrupt Vector Table (7/9): Vector Number 214 and 215, modified
		371	Figure 12.8 Register Rewrite Flow: The processing, modified
		13. Internal Buses	
		386	Table 13.1 Specifications of Internal Buses: The contents of external serial flash bus, modified (PCLKD → ICLK)
		387	Figure 13.1 Bus Configuration: Serial Flash (PCLKD) → Serial Flash, modified

Rev.	Date	Description	
		Page	Summary
1.30	Apr. 25, 2017	388	Figure 13.2 Bus Configuration (for products incorporating an R-IN engine): Serial Flash (PCLKD) → Serial Flash, modified
		15. DMA Controller (DMACAa)	
		577	15.6 Usage Notes: The note, added
		19. Multi-Function Timer Pulse Unit (MTU3a)	
		696	19.2.1 Timer Control Register (TCR): The functional description of the TPSC[2:0] bits in the table of bits, modified (The reference, modified)
		812	19.3.6, (4) 32-bit Phase Counting Mode Application Example: The description, modified
		880	19.4.2, (1) DMAC Activation: The description, deleted
		20. Port Output Enable 3 (POE3)	
		978	20.6.1 Transition to Low Power Consumption Mode: Deleted
		28. Ethernet MAC (ETHERC)	
		1328	28.2.2.6 TX MODE Register (GMAC_TXMODE): The functional description of the TEMPTH[2:0] bits in the table of bits, modified
		32. USB 2.0 HS Function Module (USBf)	
		1777	Table 32.23 Pipe Settings: The DCPCFG register, deleted
		1779	32.5.3 Pipe Control Register Switching Procedures: The DCPCFG register, deleted
		37. SPI Multi I/O Bus Controller (SPIBSC)	
		2155	Table 37.1 SPIBSC Specifications: The contents of the bit rate, modified (PCLKA → ICLK)
		2156	Figure 37.1 Block Diagram of SPIBSC: PCLKA → ICLK, modified
		2162	37.2.3, (1) Bit Rate: PCLKA → ICLK, modified
		2162	Table 37.3 Relationship between SPBR[7:0] and BRDV[1:0] Settings: Bit Rate, PCLKA → ICLK, modified. Setting of bits SPBR[7:0] and BRDV[1:0]: 0,1, 0,2, and 0,3, added.
		47. Electrical Characteristics	
		2547	Figure 47.60 SPIBSC Transmit/Receive Timing (CPHAT = 0, CPHAR = 1): Modified
1.40	Jan. 19, 2018	All	Cortex-R4F changed to Cortex-R4
			Terms corrected (Ether Switch → Ethernet switch; Ether Mac → Ethernet Mac; Ether PHY → Ethernet PHY; Ether clock(s) → Ethernet clock(s); receive buffer(s) → reception buffer(s); transmit buffer(s) → transmission buffer(s); transmit/receive buffer(s) → transmission/reception buffer(s); transmit mode → transmission mode; receive mode → reception mode; compare match counter (CMCNT) → compare match timer counter (CMCNT); compare match constant register (CMCOR) → compare match timer constant register (CMCOR); low active → active low; high active → active high; valley → trough)
		Features	
		54	■ Encoder interfaces, changed ■ Various communications interfaces: Features of Ethernet changed
		1. Overview	
		55	1.1 Outline of Specifications: "Cortex®-R4F processor" changed to "Cortex®-R4 processor with FPU"
		55	Table 1.1 Outline of Specifications (1 / 7): Registered trademark symbol added to "Thumb"; description of "Clock" changed
		61	Table 1.1 Outline of Specifications (7 / 7): Description of the encoder interfaces changed
		69	Table 1.4 Pin Functions (4 / 7): CTS0# to CTS4#: I/O and functional description changed; RTS0# to RTS4#: Functional description changed
		72	Table 1.4 Pin Functions (7 / 7): ENCIF07 to ENCIF12 changed to ENCIF00 to ENCIF12
		75	Table 1.5 Pin Assignments (320-Pin FBGA) (1 / 8): ENCIF12 added to B19; ENCIF11 added to B20
		76	Table 1.5 Pin Assignments (320-Pin FBGA) (2 / 8): ENCIF10 added to C19; ENCIF09 added to D19; ENCIF08 added to E19
		77	Table 1.5 Pin Assignments (320-Pin FBGA) (3 / 8): ENCIF11 added to H19; ENCIF12 added to H20

Rev.	Date	Description	
		Page	Summary
1.40	Jan. 19, 2018	78	Table 1.5 Pin Assignments (320-Pin FBGA) (4 / 8): ENCIF10 added to J19
		79	Table 1.5 Pin Assignments (320-Pin FBGA) (5 / 8): ENCIF09 added to N20; ENCIF08 added to P20
		80	Table 1.5 Pin Assignments (320-Pin FBGA) (6 / 8): ENCIF09 added to U3
		81	Table 1.5 Pin Assignments (320-Pin FBGA) (7 / 8): ENCIF10 added to W3; ENCIF11 added to W4; ENCIF08 added to W10; ENCIF12 added to Y4
		88	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (2 / 10): ENCIF12 added to B19 under "Others"; ENCIF11 added to B20 under "Others"
		89	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (3 / 10): ENCIF10 added to C19 under "Others"; ENCIF09 added to D19 under "Others"; ENCIF08 added to E19 under "Others"
		91	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (5 / 10); ENCIF11 added to H19 under "Others"; ENCIF12 added to H20 under "Others"; ENCIF10 added to J19 under "Others"
		93	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (7 / 10): ENCIF09 added to N20 under "Others"; ENCIF08 added to P20 under "Others"
		94	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (8 / 10): ENCIF09 added to U3 under "Others"
		95	Table 1.7 List of Pin and Pin Functions (320-Pin FBGA) (9 / 10): ENCIF10 added to W3 under "Others"; ENCIF11 added to W4 under "Others"; ENCIF08 added to W10 under "Others; ENCIF12 added to Y4
		3. Operating Modes	
		113	Table 3.3 Parameter Information for the Loader in 16-bit or 32-bit Bus Boot Mode: Offset address of DEST_ADDR_NML changed (0000 000Ch → 0000 001Ch)
		114	Table 3.4 Parameter Information for the Loader in SPI Boot Mode: Offset address of DEST_ADDR_NML changed (0000 000Ch → 0000 001Ch)
		115	3.5.3 Loader Program: Description modified
		115	Figure 3.3 Connection Diagram of This LSI with a Serial Flash Memory: Pins in serial flash memory changed (SI/SIO0 → SO/SIO1, SI/SIO1 → SI/SIO0)
		4. Address Space	
		125	Figure 4.1 Memory Map: Encoder I/F area (16 MB) added; Address 1000 0000h added to the USB; Note 2 changed; Note 9 added
		126	Figure 4.2 Memory Map (1-Mbyte Extended Internal SRAM): Encoder I/F area (16 MB) added; Address 1000 0000h added to the USB; Note 5 added
		127	Figure 4.3 Memory Map (0-Kbyte Extended Internal SRAM): Address 1000 0000h added to the USB
		5. I/O Registers	
		138	Table 5.1 List of I/O Registers (Address Order) (10 / 86): Interrupt level control register 8 (LVLC8) and interrupt level control register 9 (LVLC9) added
		152	Table 5.1 List of I/O Registers (Address Order) (24 / 86): Register name corrected (HcPeriodCurED register → HcPeriodicCurrentED register)
		153	Table 5.1 List of I/O Registers (Address Order) (25 / 86): Number of bits and access size of the CFIFO port register, D0FIFO port register, and D1FIFO port register changed
		180	Table 5.1 List of I/O Registers (Address Order) (52 / 86): XYZ short abnormality detection 0 data input threshold setting register and XYZ short abnormality detection 1 data input threshold setting register moved
		199	Table 5.1 List of I/O Registers (Address Order) (71 / 86): Event link setting register 16 (ELSR16) and event link setting register 28 (ELSR28) added
		210	Table 5.1 List of I/O Registers (Address Order) (82 / 86): Register symbol of the timer offset correction count register corrected (ATIME_CORR_OFFS → ATIME_OFFS_CORR)
		211	Table 5.1 List of I/O Registers (Address Order) (83 / 86): PHY Port Status n Register (PHY_STATUSn) deleted
		6. Reset	
		215	Table 6.2 Targets to Be Initialized for Each Reset Type: Reset sources for RSTOUT# pin output and ERROROUT# pin output changed

Rev.	Date	Description	
		Page	Summary
1.40	Jan. 19, 2018	7. Clock Generation Circuit	
		244	7.9.1 Notes on Clock Generation Circuit (7): Description in (7) corrected ("channels 0 to 45" → "channels 0 to 4")
		9. Low-Power Consumption Function	
		261	9.2.5 Module Stop Control Register E (MSTPCRE): Note 1 added to the bit table (MSTPCRE0 bit)
		10. Debugging Interface	
		281	Table 10.10 Available Trace Functions: Module name corrected (Cortex-R4 → Cortex-R4 (CR4), Cortex-M3 → Cortex-M3 (CM3))
		12. Interrupt Controller (ICUA)	
		285	Table 12.1 Specifications of Interrupt Controller: Note 2 modified (CR4F → CR4)
		286	Figure 12.2 Block Diagram of Interrupt Controller (for products incorporating an R-IN engine): MTU3a ch6.7 source selection (ISEL) deleted
		291	12.2.4 Non-maskable Interrupt Status Register (NMISR): "NMI Error Status Flag" in the bit table corrected to "ECM Error Status Flag"
		294	12.2.8 NMI Pin Digital Noise Filter Setting Register (NMIFLTC): Bits "b7 to b2" in the bit table changed to "b31 to b2"
		355	12.4.2.16 Interrupt Address Store Register 0 (VADn), Interrupt Address Store Register 1 (VADn): Description of the VADi[31:0] bits corrected
		358, 359	12.4.2.19 Interrupt Level Control Register n (LVLCn), added
		361	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (1 / 10): Request source for vector numbers 1 to 3 modified (System (CR4F) → System (CR4))
		365	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (4 / 10): Vector numbers 129 to 144: Encoder I/F (ENCINT0 to ENCINT15) added
		371	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table: Notes 5 and 6 added
		372	Figure 12.6 Initializing Registers of VIC: Processing changed (LVLCr added)
		373	12.4.4.2 Procedure for Rewriting the PLS, LVLCr, PRLM, VAD, and PRL Registers: LVLC register added
		375	12.4.4.3, (1) Specifying Interrupt Detection Types, Description changed
		375	Table 12.4 VIC Settings by Interrupt Detection Type: Interrupt request types LVCx1 and LVCx0 added
		384	12.4.6.6 Notes on Vector Settings, added
		386 to 389	Table 12.6 CM3 Interrupt Vector Table: DMAC setting vector numbers changed, Note 4 added
		14. Bus State Controller	
		394	Table 14.1 Bus State Controller Specifications: Note 1 added
		397	Table 14.3 Address Map: Note 1 added
		399	14.3.1 CSn Space Bus Control Register (CSnBCR): R/W for b8 to b0 changed
		403	14.3.2 CSn Space Wait Control Register (CSnWCR), (3), CS3WCR_1: Note 1 added
		424	14.3.7 Timeout Cycle Constant Register (TOSCORn): Description of b15 to b0 in the bit table modified
		428	14.3.10 CKIO Control Register (CIOSET): The description, modified
		473	Table 14.16 Output Addresses when EMRS Command Is Issued: Entries for CS2 MRS and CS3 MRS under "EMRS Command Issue Address", modified
		15. DMA Controller (DMACAa)	
		523	15.2.26 DMA Status SUS Register (DST_SUS_X (X = A or B)): Addresses corrected
		531	Figure 15.7 Link Mode Overview: "Memory" changed to "External memory"
		548	Table 15.21 DMA Transfer Request Detection Operation Setting Table (3 / 6): DMA transfer source for MTU3a corrected (TCID6 → TGID6)
		551	Table 15.21 DMA Transfer Request Detection Operation Setting Table: Note 4 added

Rev.	Date	Description	
		Page	Summary
1.40	Jan. 19, 2018	16. Event Link Controller (ELC)	
		585	16.2.2 Event Link Setting Register n (ELSRn): n = 16, 28 added
		587	Table 16.3 Correspondence between Event Signal Names Set in ELSRn.ELS[7:0] Bits and Signal Numbers (1 / 3): Event signals set in ELSRn of the Ethernet controller changed
		595	16.2.8 Port Group Control Register n (PGCn): Symbol PGCInl[1:0] corrected to PGCIn[1:0]
		601	16.2.14 Event Link Option Setting Register I (ELOPI): Symbol GPT2MD corrected to GPT0MD
		17. I/O Ports	
		622	17.3.3 Port Input Register (PIDR): Address corrected
		626	Table 17.3 Handling of Unused Pins: Handling of EXTAL changed; USB_RREF pin added; Note 1 added
		18. Multi-Function Pin Controller (MPC)	
		647	Table 18.1 List of Multiplexed Pin Configurations (21 / 22): ENCIF08 to ENCIF12 added to "Encoder I/F"
		651	Table 18.3 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: PSEL[5:0] = 101011b added
		654	18.2.5 P3n Pin Function Control Register (P3nPFS): ISEL Bit (Interrupt Input Function Select), description added
		664	Table 18.17 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: Pin functions added to P94 and P96 for 101011b
		678	Table 18.30 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: PSEL[5:0] = 101011b added
		681	Table 18.33 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: PSEL[5:0] = 101011b added
		683	Table 18.35 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: Pin function added to PR1 for 101011b
		685	Table 18.37 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: Pin functions added to PT1, PT3, and PT7 for 101011b
		19. Multi-Function Timer Pulse Unit (MTU3a)	
		694	Table 19.1 Specifications of the MTU: Description of available operations of [MTU1, MTU2] changed
		696	Table 19.2 Functions of the MTU (2 / 3): Entries added to MTU6 and MTU7 for event link function (input)
		885	Table 19.78 MTU Interrupt Sources: Note 2 added
		929 to 934	Figures 19.164 to 19.171: Step numbers corrected ((8), (9) → (7), (8))
		20. Port Output Enable 3 (POE3)	
		962	20.2.12 Port Output Enable Control Register 2 (POECR2): Address corrected
		967	20.2.15 Port Output Enable Control Register 5 (POECR5): Symbols of b1, b2 and b4 corrected
		21. General PWM Timer (GPTa)	
		990	21.2.2 Noise Filter Control Register (NFCR): Symbol of b7 corrected
		1006	21.2.14 General PWM Timer Control Register (GTCR): CCLR[1:0] Bits: Description added; "CCLR[1:0] Bits (Counter Clear)" corrected to "CCLR[1:0] Bits (Counter Clear Source Select)"
		1007	21.2.15 General PWM Timer Buffer Enable Register (GTBER): PR[1:0] Bits: Description added
		1013	21.2.21 General PWM Timer Cycle Setting Register (GTPR): Description added
		1032	21.3.2.1 GTPR Register Buffer Operation: Description added
		—	Figure 21.14 Example of GTPR Buffer Operation (Saw Waves in Down-Count Operation), deleted
		1091, 1092	Figures 21.71 and 21.73: GPTR changed to GTPR
		22. 16-Bit Timer Pulse Unit (TPUa)	
		1159	22.3.3, (2) Examples of Buffer Operation, (a) When TPUm.TGRy is an output compare register: Title corrected (TPUm.TCNT → TPUm.TGRy)
		1163	22.3.4 Cascaded Operation: Note 2 added

Rev.	Date	Description	
		Page	Summary
1.40	Jan. 19, 2018	1164	22.3.4, (2) Examples of Cascaded Operation: Description added
		1164	Figure 22.20 Example of Cascaded Operation (1): Waveforms of TPU1.TCNT and TPU2.TCNT clock signals changed
		1166	Table 22.25 PWM Output Registers and Output Pins: Description of note modified
		1203	22.9.16 Input Capture Operation in Cascaded Operation, added
		24. Compare Match Timer (CMT)	
		1235	Table 24.1 CMT Specifications: Entries as the number of internal channels changed
		1235	Figure 24.1 Block Diagram of CMT (Units 0 to 2): Units 1 and 2 added
		1238	24.2.4 Compare Match Timer Control Register (CMCR): Addresses added; Description of CKS[1:0] and CMIE in the bit table modified
		1239	24.2.5 Compare Match Timer Counter (CMCNT): Addresses added
		1239	24.2.6 Compare Match Timer Constant Register (CMCOR): Note 1 added; addresses added
		1241	24.4.2 Timing of Compare Match Interrupt Generation: Description modified
		25. Compare Match Timer W (CMTW)	
		1258	25.2.5 Compare Match Constant Register (CMWCOR): Description added
		26. Watchdog Timer (WDTA)	
		1289	Table 26.3 Relationship between Timeout Period and Window Start/End Counter Values: b1 and b0 added under "TOPS[1:0] Bits"
		1292	26.2.4 WDT Reset Control Register (WDTRCR): R/W for b6 to b0 changed
		28. Ethernet MAC (ETHERC)	
		1322	Table 28.3 I/O Pin Functions for ETHERC, added
		1334	28.2.2.5 RX MODE Register (GMAC_RXMODE): Note 1 added to the bit table (AFILLTEREN bit)
		1361	Table 28.7 HWFNC_LongBuffer_Get: Descriptions of argument registers and return value registers changed
		1362	Table 28.8 HWFNC_ShortBuffer_Get: Descriptions of argument registers and return value registers changed
		1362	Table 28.9 HWFNC_Buffer_Release: Descriptions of argument registers and return value registers changed
		1363	Table 28.10 HWFNC_Buffer_Return: Descriptions of argument registers and return value registers changed
		1368	28.3.1.4, (2) DMA for the reception MAC, (b) Usage: Bit name corrected (LBID[6:0] → LLID[6:0])
		1369	Table 28.11 HWFNC_MACDMA_RX_Enable: Descriptions of argument registers and return value registers changed
		1370	Table 28.12 HWFNC_MACDMA_RX_Disable: Descriptions of argument registers and return value registers changed
		1371	Table 28.13 HWFNC_MACDMA_RX_Control: Descriptions of argument registers and return value registers changed
		1371	Table 28.14 HWFNC_MACDMA_RX_Errstat: Descriptions of argument registers and return value registers changed
		1374	Table 28.15 HWFNC_MACDMA_TX_Start: Descriptions of argument registers and return value registers changed
		1374	Table 28.16 HWFNC_MACDMA_TX_Errstat: Descriptions of argument registers and return value registers changed
		1376	Table 28.17 HWFNC_Direct_Memory_Transfer: Description of "Function" partially deleted; descriptions of argument registers and return value registers changed
		1377	Table 28.18 HWFNC_Direct_Memory_Replace: Description of "Function" modified; descriptions of argument registers and return value registers changed
		1378	Table 28.19 Interrupts related to Operations for Transmission: TX FIFO error interrupt (ETHTFIE): Description under "Conditions for Asserting and De-asserting Interrupts" changed
		1382	28.3.3.2, (1) Transmission frame control information: Entries in the table below Figure 28.14 changed (descriptions of TX_WORD[12:0] and APAD modified); Note 2 added

Rev.	Date	Description	
		Page	Summary
1.40	Jan. 19, 2018	1383	28.3.3.2, (2) Ethernet frame: Description changed
		1383	Figure 28.16 Format for Transmission Data (TCPIP Accelerator Enabled, VLAN Tag Included): VLAN tag (2 bytes) corrected to VLAN info (2 bytes)
		—	28.3.3.3 Creating transmit descriptors: Description of the restrictions deleted
		1388	28.3.4.6 Format of received data: Misdescription corrected
		1389	28.3.4.6, (1) Received frame information: Note 2 added to the table below Figure 28.21
		1395	Table 28.22 GMAC_ACC Register Settings and Transmission TCPIP Accelerator Operation: Note 2 added
		1396	28.3.5.2 Reception with Use of the TCPIP Accelerator: Description added Table 28.23 GMAC_ACC Register Settings and Reception TCPIP Accelerator Operation: Note changed
		1398	28.4.4 Misjudgment of the Result of Checksum Calculation in Reception, added
		1399 to 1403	28.4.5 Incorrect Information on Received Frames when the Reception FIFO Overflows, added
		1404, 1405	28.4.6 Incorrect Information on Received Frames with Size, Inclusive of Padding, Exceeding 64 Bytes, added
		29. Ethernet Switch	
		1425	29.2.2.13 Internal Queue Interface Status Register (QMGR_IFACE_STAT): Symbols of b2 to b0 in the bit chart corrected
		1435	29.2.3.1 Learning Record A Register (LRN_REC_A): Symbols modified
		1439	29.2.4.2 Maximum Frame Length Register n (FRM_LENGTHn) (Shared): Title corrected
		1464	29.2.6.4 DLR Interrupt Control Register (DLR_IRQ_CTRL): Symbol of b9 in the bit chart corrected
		30. EtherCAT Slave Controller (optional)	
		1520	30.3.2 EtherCAT Operation Mode Setting Register (CATEMMD): Symbol of b0 in the bit chart corrected
		1535	30.8.1 AL Control Register (AL_CONTROL): b5 (DEVICEID bit) added
		1536	30.8.2 AL Status Register (AL_STATUS): b5 (DEVICEID bit) added
		1541	30.9.3 PDI Configuration Register (PDI_CONFIG): Functional description of b7 to b5 (ONCHIPBUS bits) in the bit table changed (100 → 010)
		—	30.14.7 PHY Port Status n Register (PHY_STATUSn), deleted
		1596	30.20 Configuration of the Reset Circuit, added
		31. USB2.0HS Host Module (USBh)	
		1602	Table 31.1 Register Mapping List (1 / 2): Name of the HcPeriodCurED register at A004 001Ch corrected (HcPeriodCurrentED → HcPeriodicCurrentED)
		1618	31.3.1.11 HcBulkHeadED Register: Bit numbers of BulkHeadED[27:0] corrected
		1625	31.3.1.21 HcRhStatus_A, HcRhStatus_B Register, (1) HcRhStatus_A Register and (2) HcRhStatus_B Register: Bit numbers of reserved bits corrected
		1633	31.3.2.2 HCSPARAMS Register: Symbol of b7 in the bit chart corrected
		1666	31.3.4.8 Offset 34h Register (Capability Pointer): Bit numbers of reserved bits corrected
		33. Serial Communications Interface with FIFO (SCIFA)	
		1818, 1819	33.2.8 Bit Rate Register (BRR): Register symbol corrected (SMER → SEMR)
		1822	33.2.9 Modulation Duty Register (MDDR): [Asynchronous mode] o When the baud rate generator is in double-speed mode (SEMR.BGDM = 1): Value in the formula under (When operating on the base clock with a frequency 16 times the bit rate (SEMR.ABCS0 = 0)) corrected (64 → 16)
		1846	33.3.3, (3) Transmitting and Receiving Data: Receiving Serial Data (in Clock Synchronous Mode): Description changed
		1858	33.8.6 Receive Data Sampling Timing and Receive Margin in Asynchronous Mode: Description partially deleted

Rev.	Date	Description	
		Page	Summary
1.40	Jan. 19, 2018	35. CAN Interface (RSCAN)	
		1964	35.2.15 Reception Rule Pointer 0 Registers (RSCAN0GAFLP0j): Symbol of b15 in the bit chart corrected
		2006	Table 35.5 TMTRSTSp Bit Assignment: Transmission buffer numbers corrected
		2007	Table 35.6 TMTARSTSp Bit Assignment: Transmission buffer numbers corrected
		2008	Table 35.7 TMTCSTSp Bit Assignment: Transmission buffer numbers corrected
		2009	Table 35.8 TMTASTSp Bit Assignment: Transmission buffer numbers corrected
		2010	Table 35.9 TMIEp Bit Assignment: Transmission buffer numbers corrected
		2016	Table 35.10 Transmission Buffers p Allocated to the Transmission Queue of Each Channel, changed
		2044	Table 35.18 Registers Initialized Only in Global Reset Mode: Register name corrected (RSCAN0RMNDy register → RSCAN0RMND0 register)
		2064	Figure 35.20 Buffer Configuration, changed
		36. Serial Peripheral Interface (RSPIa)	
		2111	36.2.14 RSPI Command Registers 0 to 7 (SPCMD0 to SPCMD7): b6 to b4 (SSLy[2:0] bits) in the bit table: Description of 010 and 011 corrected; register symbol corrected (SSLA[2:0] → SSLy[2:0])
		2115	Table 36.7 MOSI Signal Value Determination during SSL Negation Period: Note added
		37. SPI Multi I/O Bus Controller (SPIBSC)	
		2171	37.2.1 Common Control Register (CMNCR): Description of the CPHAR bit changed
		2187	37.2.13 SPI Mode Enable Setting Register (SMENR): Notes added to the description of the DME bit
		2189	37.2.14 SPI Mode Read Data Register 0 (SMRDR0): Description added
		2189	37.2.15 SPI Mode Write Data Register 0 (SMWDR0): Description added
		2198	Figure 37.8 Burst Read Operation Timing (SSLE Bit = 0), changed
		40. Boundary Scan	
		2266	Table 40.7 Explanation of States: "Select IR Scan" under "State" corrected
		41. ΔΣ Interface (DSMIF)	
		2270	Table 41.1 DSMIF Specifications: Description of functions changed (m = 0 to 2 → m = 0 to 2, 3)
		2291	41.2.22 XYZ Status Register (XYZSTA): b7 in the bit table moved
		43. 12-Bit A/D Converter (S12ADCa)	
		2374	Table 43.1 Specifications of 12-Bit A/D Converter (1 / 2): Specifications of "Conversion time" modified
		2385	43.2.2 A/D Self-Diagnosis Data Register (ADRD): o The settings for flush-left data with 10-bit accuracy: Bit name corrected (Converted Value 11 to 0 → Converted Value 9 to 0)
		2385	43.2.2 A/D Self-Diagnosis Data Register (ADRD): o The settings for flush-left data with 8-bit accuracy: Bit numbers corrected (b15 to b4 → b15 to b8) and bit name corrected (Converted Value 11 to 0 → Converted Value 7 to 0)
		2405	43.2.12 A/D Sampling State Register n (ADSSTRn): Address and values after reset changed
		46. RAM (Product Option)	
		2503	46.3.1 Configuration of Memory Map: Description modified
		47. Electrical Characteristics	
		2509	Table 47.3 DC Characteristics (2) [Power Supply]: Entries added to the "300MHz" row of VDD
		2521, 2522	Table 47.17 Bus Timing: "CKIO = 75MHz" changed to "CKIO = 1/tCKcyc; "tcyc" changed to "tCKcyc"; entries for "Address delay time 1", "CS# delay time 1", "Read/write delay time 1", "Read data setup time 1 to 3" and "WAIT# setup time" changed; Notes 1, 3, and 4 changed
		2558	Table 47.27 RSPIa Timing: Note 2 changed (SSLND → SPCKD): Note 3 added
		2567	Figure 47.64 RIICa Bus Interface Input/Output Timing: SDA0 to SDA3 and SCL0 to SCL3 deleted

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	All	The company name, modified (ARM → Arm)
		Features	
		55	■ Encoder interfaces (optional): The descriptions and related note 4, added
		Section 1 Overview	
		56	Table 1.1 Outline of Specifications (1/7): Central processing unit (Cortex-M3): The architecture type, corrected (Arm v7-R architecture → Arm v7-M architecture)
		56	Table 1.1 Outline of Specifications (1/7): On-chip extended SRAM with ECC: The entry "Operating frequency", added
		56	Table 1.1 Outline of Specifications (1/7): Operating modes: The description, modified
		57	Table 1.1 Outline of Specifications (2/7): DMAC: Activation sources, modified
		57	Table 1.1 Outline of Specifications (2/7): ELC: The number of event signals, modified
		58	Table 1.1 Outline of Specifications (3/7): TPUa: The descriptions for pulse input/output, PWM mode, PPG output trigger, event linking, modified
		58	Table 1.1 Outline of Specifications (3/7): MTU3a: The number of counter-input clock signals, modified; the feature "automatic transfer of register data", deleted; the description of phase-counting mode, modified
		59	Table 1.1 Outline of Specifications (4/7): CMT: Event linking, modified
		59	Table 1.1 Outline of Specifications (4/7): POE3: Pin names, corrected
		60	Table 1.1 Outline of Specifications (5/7): ETHERC: The description in relation with "1 port", modified
		61	Table 1.1 Outline of Specifications (6/7): SSI: "programmable word clock", deleted from the clock to be generated
		61	Table 1.1 Outline of Specifications (6/7): DSMIF: The description in relation with channel, modified
		62	Table 1.1 Outline of Specifications (7/7): Encoder interfaces: The number of channels and note 6, added
		66	Figure 1.1 Block Diagram: The number of channels of MTU3a and DSMIF, modified
		68	Table 1.4 Pin Functions (2/7): Pin names, modified (A0 to A25 → A25 to A0, D0 to D31 → D31 to D0); the "Description" column for RAS# and CAS#, modified
		69	Table 1.4 Pin Functions (3/7): The "Description" column for MTIOC8A to MTIOC8D and for GPTa, modified
		70	Table 1.4 Pin Functions (4/7): The "Description" column for each TPUa pin, modified
		71	Table 1.4 Pin Functions (5/7): Ethernet controller (ETHERC): ETH0_RXC, ETH1_RXC, ETH2_RXC: The "I/O" and "Description" columns, modified (I/O → Input, Receive clock I/O pins → Receive clock input pins)
		72	Table 1.4 Pin Functions (6/7): The AUDIO_CLK pin, added
		2. CPU	
		106	2.4.1 ATCM Wait Control Register: Note 1 to the bit table, modified
		109	2.5.2 Handling of Semaphore Register n: The section, added
		3. Operating Modes	
		111	3.4.1 Mode Monitor Register: Bit map: Value after reset for b24, modified
		112	3.5.1 Boot Function: Step (3), modified
		112	Figure 3.1 Operating Overview of Boot Processing: Step (3), modified
		113	Figure 3.2 Memory Assignment of the Loader Program and Parameters for the Loader: Note 3, modified
		114	Table 3.3 Parameter Information for the Loader in 16-bit or 32-bit Bus Boot Mode: Note 3, modified
		115	Table 3.4 Parameter Information for the Loader in SPI Boot Mode: Note 3, added (former note 3 renumbered as note 4)
		116	3.5.3 Loader Program: The descriptions for external memory storage address: The address range in 16-/32-bit bus boot mode, modified; the address range in SPI boot mode, added

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	117	Table 3.5 Setting Values of the Individual Peripheral Modules and Registers at the Time SPI Boot Mode Finishes: The "Setting Value at the Time the Boot Processing Finishes" column for the MSTPCRC, PORT6.PMR, and MPC.PmnPFS registers, modified
		121	Table 3.8 Setting Values of the Individual Peripheral Modules and Registers at the Time 16-bit or 32-bit Bus Boot Mode Finishes: The "Setting Value at the Time the Boot Processing Finishes" column for the MSTPCRC, PORTn.PMR, and MPC.PmnPFS registers, modified
		4. Address Space	
		126	Figure 4.1 Memory Map: Cortex-M3: A bit width and size of BitBand Alias Area0, modified (2200 0000h to 2300 0000h (16 MB) → 2200 0000h to 2400 0000h (32 MB)); notes 6 and 7, deleted
		127	Figure 4.2 Memory Map (1-Mbyte Extended Internal SRAM): The maps for A000 0000h Cortex-R4 and DMAC0/DMAC1: Peripheral I/O register (1MB): Note 3, added
		128	Figure 4.3 Memory Map (0-Kbyte Extended Internal SRAM): The maps for Cortex-R4 and DMAC0/DMAC1: B000 0000h to B100 0000h Encoder I/F area (16 MB); added, note 5, added
		5. I/O Registers	
		132	Table 5.1 List of I/O Registers (Address Order) (3/86): Access size for the DSCR register, modified
		153	Table 5.1 List of I/O Registers (Address Order) (24/86): The HcLSThreshold register, deleted
		154	Table 5.1 List of I/O Registers (Address Order) (25/86): Register names of DVSTCTR0, TESTMODE, and SOFCFG, modified
		155	Table 5.1 List of I/O Registers (Address Order) (26/86): The register name of UFRMNUM, modified
		155	Table 5.1 List of I/O Registers (Address Order) (26/86): The LPCTRL and PHYFUNCTR registers, deleted
		180	Table 5.1 List of I/O Registers (Address Order) (51/86): Register names of V1CDATA, V1VDATA, W1CDATA, and W1VDATA, modified
		182	Table 5.1 List of I/O Registers (Address Order) (53/86): Regitser name of RSCAN0FMSTS, modified
		214	Table 5.1 List of I/O Registers (Address Order) (85/86): Register names of GMAC_FLWCTL, GMAC_PAUSPKT, and GMAC_MIIM, modified
		6. Reset	
		221	6.3.1 RES# Pin Reset: The description in relation to a waiting time for PLL0 oscillation stabilization (tPL0WT), deleted
		221	6.3.2 ECM Reset: The description in relation to a waiting time for PLL0 oscillation stablization (tPL0WT), deleted
		221	6.3.3 Software Reset: The description in relation to a waiting time for PLL0 oscillation stablization (tPL0WT), deleted
		223	6.4 Usage Note: 6.4.1 Connection of Reset Output Pin (RSTOUT#), added
		7. Clock Generation Circuit	
		225	Table 7.2 Specifications of Clock Generation Circuit (Internal Clock) (1/2): The frequency of PCLKE, modified
		226	Table 7.2 Specifications of Clock Generation Circuit (Internal Clock) (2/2): The frequencies of CLMAPLCLK1 and TCLK, modified; note 1, added
		227	Figure 7.1 Block Diagram of Clock Generation Circuit: Clock names, modified (ACLK → AUDIO_CLK, AUDIOCLK → ATCLK)
		228	Figure 7.2 Block Diagram of Clock Generation Circuit (for products incorporating an R-IN engine): Clock names, modified (ACLK → AUDIO_CLK, AUDIOCLK → ATCLK)
		230, 231	7.2.1 System Clock Control Register: Bit table, modified (b13 (reserved) → b11 (reserved), b13 (reserved), added); the "Description" column for b20 (TCLK), modified
		233, 234	7.2.3 Delta-Sigma Interface Clock Control Register: Bit table: The description of the MCLK pin, modified
		235	7.2.4 PLL1 Control Register: Bit table: Note 1, modified
		238	7.2.6 Low-Speed On-Chip Oscillator Control Register (LOCOCR): The register name, modified (the low-speed on-chip oscillator control register → the LOCOCR register)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	239	7.2.7 Oscillation Stop Detection Control Register (OSTDCR): Bit table: Note 1, modified
		240	7.3 Selecting Input to Main Clock Oscillator: The reference destination (table), corrected
		242	7.4.1 Oscillation Stop Detection and Operation after Detection: A section for reference, added
		243	7.8 Internal Clock: (9), CLMA clocks, modified
		244	7.8.9 USB Clock M (USBMCLK): The description, added
		244	7.8.12 CLMA Clock (CLMAMCLKA, CLMAMCLKB, CLMALCLK, CLMAPLCLK0, and CLMAPLCLK1): The title and body, modified
		244	7.8.14 ECM Clock (ECMCLK): The description, added
		245	7.8.16 Delta-Sigma Interface Clock 0 (DSCLK0): The description partially modified, (clock generation circuit → clock generation circuit (PLL0))
		245	7.8.17 Delta-Sigma Interface Clock 1 (DSCLK1): The description partially modified, (clock generation circuit → clock generation circuit (PLL0))
		245	7.8.19 Trace Interface Clock (TCLK): The description, added
		246	7.9.1 Notes on Clock Generation Circuit: The descriptions on (3) to (7), modified
		9. Low-Power Consumption Function	
		258	Table 9.2 Stopping Peripheral Modules and Exiting Module-Stop State (2/2): Ethernet MAC/HW-RTOS (for products incorporating an R-IN engine), added
		259	9.2 Register Descriptions: The body, modified
		270	9.4.5 Low Power Consumption for Ethernet-Related Functions: The description partially modified (the MSTPCRB.MSTPCRB14 to MSTPCRB17 bits → the MSTPCRB.MSTPCRB14 to MSTPCRB19 bits)
		10. Debugging Interface	
		271	10.1 Overview: A figure for reference, added
		271	Table 10.1 CoreSight Specifications: The description for trace port interface, modified
		276	Table 10.8 Configuration of Pins for the Debugging Interface: Note 1, modified
		280	10.3.3 Trace Port Interface: The description for 75 MHz, deleted
		11. Register Write Protection Function	
		287	11.2.1 Protect Register: The values represented by the suffix "i" of the PRCi bit, modified
		12. Interrupt Controller	
		288	12.1 Overview: The body, modified
		288	Table 12.1 Specifications of Interrupt Controller: Note 3, added
		291	12.2.1 IRQ Control Register i: A note, added
		293	12.2.3 IRQ Pin Digital Noise Filter Setting Register: The description for the FCLKSELi[1:0] bits, modified
		298	12.2.9 EtherPHY Control Register i: Bit table, modified (b7 to b4 (reserved) → b31 to b4 (reserved))
		299	12.2.10 Ethernet PHY Interrupt Request Pin Digital Noise Filter Enable Register: Bit table, modified (b31 to b2 (reserved) → b31 to b3 (reserved))
		302	12.2.13 External DMA Request Pin Digital Noise Setting Register: Bit table, modified (b7, b6 (reserved) → b31 to b6 (reserved))
		304	12.3.1 Selecting Interrupt Request Destinations: The body, modified; a note, added
		304	Figure 12.3 DMAC as the Interrupt Request Destination: The title, modified; the description, added
		305	Figure 12.4 CPU (Interrupt Controller) as the Interrupt Request Destination: The title, modified; the description, added
		306	12.3.2 Digital Noise Filter: The description in relation with the sampling cycle, modified
		307	12.3.3 External Pin Interrupts: The body, modified
		309	12.4 Cortex-R4 Vector Interrupt Controller (VIC), 12.4.1 Overview: The body, modified
		314	12.4.2.1 IRQ Status Register n, IRQS9: Bit table, modified (b6 to b0 (IRQ[300:288]) → b12 to b0 (IRQ[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	319	12.4.2.2 Interrupt Input Status Register n, RAIS9: Bit table, modified (b6 to b0 (RAI[300:288]) → b12 to b0 (RAI[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		324	12.4.2.3 Interrupt Enable Register 0, IEN9: Bit table, modified (b6 to b0 (IEN[300:288]) → b12 to b0 (IEN[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		329	12.4.2.4 Interrupt Enable Clear Register n, IEC9: Bit table, modified (b6 to b0 (IEC[300:288]) → b12 to b0 (IEC[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		332	12.4.2.5 Interrupt Detection Type Selection Register n, PLS5: Erroneous vector number in the description of the PLSi bit (Interrupt Input Detection Type Selection) (i = 128 to 191), corrected (28 → 128):
		334	12.4.2.5 Interrupt Detection Type Selection Register n, PLS9: Bit table, modified (b6 to b0 (PLS[300:288]) → b12 to b0 (PLS[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		339	12.4.2.6 Edge Detection Bit Clear Register n, PIC9: Bit table, modified (b6 to b0 (PIC[300:288]) → b12 to b0 (PIC[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		341	12.4.2.8 Interrupt Priority Level Mask Register 1: Bit table: b15 to b0 (PRLM[15: 0]), description for the value 1, modified; the description for the PRLMi bit, modified
		351	12.4.2.14 Interrupt Service Status Register n, ISS9: Bit table, modified (b6 to b0 (ISS[300:288]) → b12 to b0 (ISS[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		357	12.4.2.15 Interrupt Service Current Register n, ISC9: Bit table, modified (b6 to b0 (ISC[300:288]) → b12 to b0 (ISC[300:288]), b31 to b7 (reserved) → b31 to b13 (reserved))
		358	12.4.2.16 Interrupt Address Store Register 0, Interrupt Address Store Register 1: The description for the VADi bit, modified
		361	12.4.2.19 Interrupt Level Control Register n, LVLC8: Bit map: Value after reset, partially modified; bit table: b0, b1 (reserved), the description, modified
		362, 363	12.4.2.19 Interrupt Level Control Register n, LVLC9: Bit map: Value after reset, partially modified; bit table: the bit symbol for b1, b0, modified; the "Description" column for b2 to b31 (reserved), modified
		380	12.4.4.3, (2) IRQ Interrupt (Level interrupt): The suffix, modified (m → n)
		384	Figure 12.11 Concept of Multiple Interrupts (2 / 2): The routine starting from interrupt request o (level 3), modified ("interrupt request 1 (level 1)" added after the interrupt request p (level 2))
		387	12.4.6.5 Notes on Vector Settings: The description, modified (offset addresses → addresses)
		393	12.6 Usage Notes: 12.6.1 Using “Falling-Edge” or “Rising and Falling Edges” Detection with the external pin interrupts, added
		393	12.6.2 Using Falling-Edge Detection with the NMI Pin, relocated (12.4.6.5 → 12.6.2)
		13. Internal Buses	
		394	Table 13.1 Specifications of Internal Buses: The bus type, modified (Memory bus 1, Memory bus 2 → Memory buses 1 and 2 (only for products incorporating an R-IN engine))
		395	Figure 13.1 Bus Configuration: Peripheral bus 1 (PCLKA) and ECAT, added
		396	Figure 13.2 Bus Configuration (for products incorporating an R-IN engine): Peripheral bus 1 (PCLKA) and ECAT, added
		397	Table 13.3 Internal Main Bus 2: Connection between Bus Master and Bus Slave: "AHB2DMA" is deleted from "AHB2DMA (Buffer RAM)", accessesibility from the CPU for Instruction RAM, Data RAM, and Buffer RAM, modified
		14. Bus State Controller	
		All	A request name, modified (timeout detection interrupt request → timeout detection error request)
		399	Figure 14.1 Block Diagram of Bus State Controller: Pin names, modified (BS → BS#, DQMxx → DQMUU, DQMUL, DQMLU, DQMLL, AH → AH#); the register name of CSnWCR, modified; note 1, added
		403, 404	14.3.1 CSn Space Bus Control Register: Bit table: b10, b9 (BSZ[1: 0]), note 1 in the description column, modified; b14-b12 (TYPE[2: 0]), note 2 added to the description column
		407	14.3.2 CSn Space Wait Control Register: (1) Normal Space, SRAM with Byte Selection, and MPX-I/O, CS0WCR_0, Bit table: b17, b16, b21, modified to reserved bits; b21 (reserved), the description, modified
		423	14.3.3 SDRAM Control Register: Bit table: The bit name of b10 (RMODE), modified (Refresh Control → Refresh Mode)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	425	14.3.4 Refresh Timer Control/Status Register: Bit map: Bit symbol of b2 to b0, modified
		427	14.3.6 Refresh Time Constant Register: The body, modified (interrupt request → interrupt request (BSCCMI)); erroneous description of b7 to b0, corrected (8-Bit Counter → 8-Bit Register)
		428	14.3.7 Timeout Cycle Constant Register: The body, modified
		440	Figure 14.8 Wait Timing for SRAM Interface Access (Software Wait Only): The description, added
		441	Figure 14.9 Wait Cycle Timing for SRAM Interface Access (Wait Cycle Insertion Using WAIT# Signal): The description, added; the signal name, modified (WAIT → WAIT#)
		442	Figure 14.10 Active Period Expansion for the CSn Signal: The description, added
		443	Figure 14.11 Access Timing for MPX Space (1): The description, added
		444	Figure 14.12 Access Timing for MPX Space (2): The description, added
		445	Figure 14.13 Access Timing for MPX Space (3): The description, added
		446	Figure 14.14 Access Timing for MPX Space (4): The description, added
		447	14.4.6, (1) SDRAM Direct Connection: The suffix "x", added
		480	14.4.7 Burst ROM (Clocked Asynchronous) Interface: The reference destination (table), corrected
		481	Table 14.17 Relationship between Bus Width, Access Size, and Number of Bursts: Note 1, modified
		484	Figure 14.37 Wait Timing for SRAM with Byte Selection (BAS = 1) (SW[1:0] = 01b, WR[3:0] = 0001b, HW[1:0] = 01b): The title, modified (the suffix "b" indicating a binary number, added)
		15. DMA Controller (DMACAa)	
		491	Table 15.1 Specifications of DMAC: Channel priority, DMA mode (register mode/link mode), skip function, modified
		498	15.2.5 Current Destination Address Register: Address(es): Register symbol, modified (CRDA_C → CRDA_8)
		503, 504	15.2.7 Channel Status Register n: Bit table: b10 (DER), b16 (INTM), the descriptions, modified
		505	15.2.8 DMAC Unit 0 Source Select Register i: The body, modified; address(es): Module symbols, modified (ICU.DMA0SELx → DMA0.DMA0SELx)
		505	15.2.9 DMAC Unit 1 Source Select Register i: The body, modified; address(es): Module symbols, modified (ICU.DMA1SELx → DMA1.DMA1SELx)
		506	15.2.10 DMAC Software Activation Register: Address(es): Module symbol, modified (ICU.DMASTG → DMAC.DMASTG)
		509	15.2.12 Channel Control Register n: Bit table: The "Symbol" and "Description" columns for b7 (CLRDE), modified; the "Description" column for b12 (SETREN), modified
		510 to 513	15.2.13 Channel Configuration Register n: Bit table: The "Description" column for b3 (REQD), b10 to b8 (AM[2:0]), b20 (SAD), b21 (DAD), modified; note 1, added
		520	15.2.20 Destination Skip Register n: Address(es): Address modified (DSKP_15: A006 36E8 → DSKP_15: A006 36ECh)
		523	15.2.22 Descriptor Interval Register n: Bit table, modified (b7 to b1 (reserved) → b7 to b0 (reserved))
		535	15.3.1.2 Link Mode: The body, modified (memory area → memory area outside the DMAC)
		535	Figure 15.7 Link Mode Overview: A notation, modified (External memory → Memory)
		538	Table 15.12 Descriptor Format: The "Channel Extension" column, deleted
		539	Table 15.13 Description of activation in Table 15.12 Descriptor Format: “Channel Extension”, deleted
		539	Table 15.14 Descriptor Placement Example: DSCFM 1h address +18h, modified ("Extension" → "—")
		539	Figure 15.9 Header Area: The description, modified
		541	Figure 15.10 Header Area: The descriptions, corrected ("External memory" → "Memory", "DMA transaction" → "DMA transfer")
		542	15.3.1.2 Link Mode, (3) Descriptor settings, The bullet item "Notes on descriptors": The body, modified (LV = 0 → LV = 1)
		543	Figure 15.11 Header Area: The description, modified ("External memory" → "Memory")

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	545	Figure 15.12 Single Transfer Mode (REQD = 1, SDS > DDS): The description, added
		546	Figure 15.13 Block Transfer Mode (REQD = 0, SDS = DDS): The description, added
		546	15.3.3.1 Fixed Priority Mode: The body, modified
		546	Figure 15.14 Priority Levels Immediately after a Reset and Transfer through DMA Channel 0, added
		547	Figure 15.15 Fixed Priority Mode (Number of Channels Is 4, and REQD = 1): The description, added; the explanation regarding DMA request, modified
		547	15.3.3.2 Round-Robin Mode: The body, modified
		547	Figure 15.16 Priority Levels Immediately after a Reset and Transfer through DMA Channel 2, added
		551	Table 15.21 DMA Transfer Request Detection Operation Setting Table (2/6): DMA Transfer Request Source/S12ADCa Unit 0, S12ADCa Unit 1, the "TM" column under CHCFG_n, modified
		562	Figure 15.26 Software Forced Ejection Timing: The description partially modified ("Sweep write" → "Forced ejection (write)")
		563	Figure 15.27 Interval Count (REQD = 0, SDS < DDS): DREQ[1], DACK[1], CHITVL1, CH1 DMA transfer, deleted; the description, added
		564	Figure 15.28 DMA Transfer Settings and Interval Counts: Cases of REQD = 0, REQD = 1, the description, added
		564	15.3.8.1 When the Transfer Data Size on the Transfer Source is Small: The body, modified
		571	Table 15.23 Interrupt Sources of DMAC: An interrupt source name, corrected ("Descriptor inbound" → "Descriptor invalid"); output condition, modified (DRRP bit → DRRP and DIM bits)
		573	Table 15.25 DMA Transfer Setting Example 1: The item "AHB setting", deleted
		575	Table 15.26 DMA Transfer Setting Example 2: The item "AHB setting", deleted
		577	Table 15.27 DMA Transfer Setting Example 3: The item "AHB setting", deleted
		585	15.6 Usage Notes: Notation, modified (SKIP transfer → skip transfer)
		16. Event Link Controller (ELC)	
		All	Throughout the section, the expressions related to restarting a counter, modified to those meaning clearing of a counter
		588	Table 16.1 ELC Specifications, Event link function: The number of event signals, modified
		589	16.2.2 Event Link Setting Register n: Address(es): The ELSR16, ELSR28 registers, added; note 1, added
		600	16.2.9 Port Buffer Register n: Bit table:The "Description" column, modified
		604	16.2.13 Event Link Option Setting Register H (ELOPH): Bit name, modified (CMTW Operation Select → CMTW0 Operation Select)
		607	Figure 16.2 Relation between Interrupt Handling and ELC (excluding the Ethernet MAC and EtherCAT): The title, modified; a block "Interrupt request (Event)", added
		608	16.3.2 Event Linkage: The body, modified
		608	Table 16.5 Operations of Modules When Event is Input: The modules MTU, CMT, CMTW, TPU, GPT: The "Operations When Event is Input" column, modified; the DSMIF module, added; I/O ports (output), I/O port (input), the "Operations When Event is Input" column, modified; note 1, added
		609	16.3.3, (2) Counting Clear Operation: The body, modified
		609	16.3.5, (1) Single ports and Port Groups: Register symbols, modified (PEL0 to PEL3 → PELn, PGCn → PGRn)
		610	16.3.5, (2) Single Input Port Operation upon Event Generation: The title and description, modified
		610	16.3.5, (3) Single Output Ports Operation upon Event Input: The description, modified
		610	Figure 16.3 Event Linkage Related to Single Ports (Port B), modified
		611	16.3.5, (4) Input Port Group Operation upon Event Generation: The title and description, modified
		611	16.3.5, (5) Input Port Group Operation upon Event Input: The entire paragraph added
		611	Figure 16.4 Input Port Group Operation upon Event Input (Port B), modified

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	—	16.3.5, (6) Operation of Port Buffer Registers, deleted
		612	16.3.5, (6) Output Port Group Operation upon Event Input: The title and description, modified
		612	Figure 16.5 Event Linkage Operation of Output Port Group (Port B), modified
		613	Figure 16.6 Bit-Rotating Operation of Output Port Groups (Port B), modified
		613	16.3.5, (7) Restrictions on Writing to PODR and PDBFn Registers by a CPU: The title and description, modified
		614	16.3.6 Example of Procedure for Linking Events: Step 2: Subheads, added
		615	16.4.1 Setting ELSR18 and ELSR19 Registers: The body, modified
		17. I/O Ports	
		618	Figure 17.1 I/O Port Configuration (1): Note 1, modified
		619	Figure 17.2 I/O Port Configuration (2): Note 1, modified
		620	Figure 17.3 I/O Port Configuration (3): Note 1, modified
		621	Figure 17.4 I/O Port Configuration (4): Note 1, modified
		622	Figure 17.5 I/O Port Configuration (5): Note 1, deleted
		623	17.3.1 Port Direction Register: The ports covered with the index m for 176-pin products, modified (ports K to N, R to U → ports 9, J to N, P, R to U)
		624	17.3.2 Port Output Data Register: The ports covered with the index m for 176-pin products, modified (ports K to N, R to U → ports 9, J to N, P, R to U)
		626	17.3.4 Port Mode Register: The ports covered with the index m for 176-pin products, modified (ports K to N, R to U → ports 9, J to N, P, R to U)
		628	17.3.6 Driving Ability Control Register: The body, modified
		18. Multi-Function Pin Controller (MPC)	
		657	18.2.5 P3n Pin Function Control Register: Bit map: Note 1, modified
		657	Table 18.6 Register Settings for the Input/Output Function in the 320-pin FBGA Pin: Note 1, note 2, added
		660	Table 18.9 Register Settings for the Input/Output Function in the 176-pin HLQFP Pin: Setting values 000011b and 001001b, deleted
		661	Table 18.11 Register Settings for the Input/Output Function in the 176-pin HLQFP Pin: Pins for the setting value 000000b, modified
		663	Table 18.13 Register Settings for the Input/Output Function in the 176-pin HLQFP Pin: Setting values 011001b and 011110b, deleted
		665	18.2.10 P8n Pin Function Control Register: ISEL bit: The description, added
		667	18.2.11 P9n Pin Function Control Register: ISEL bit: The description, added
		674	18.2.15 PDn Pin Function Control Register: The body, modified
		679	18.2.18 PGn Pin Function Control Register: The body, modified
		682	18.2.21 PKn Pin Function Control Register: The body, modified
		685	18.2.24 PNn Pin Function Control Register: The body, modified
		692	Table 18.39 Register Settings: Note for analog inputs, modified
		19. Multi-Function Timer Pulse Unit (MTU3a)	
		698	Table 19.1 Specifications of the MTU: Operating frequency, modified, available operations [MTU1, MTU2], modified
		700	Table 19.2 Functions of the MTU (2/3): DMAC activation, modified
		701	Table 19.2 Functions of the MTU (3/3): Note 1, added (former note 1 renumbered as note 2)
		704	Table 19.3 Pin Configuration of the MTU: Function of the MTCLKA and MTCLKB pins, modified
		707	19.2.2 Timer Control Register 2: Register symbols, modified (TCRU/V/W → TCR2U/V/W)
		707	19.2.2 Timer Control Register 2: Bit table: b2 to b0 (TPSC2[2:0]): The "Description" column, modified (the reference destination table)
		710	Table 19.9 TPSC[2:0], TPSC2[2:0] (MTU3, MTU4, MTU6, MTU7, and MTU8): Note 1, deleted

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	714	Table 19.11 Operating Mode Setting by MD[3:0] Bits (MTU0 to MTU4, MTU6 to MTU8): The "Description" column for 0000b, modified
		715	19.2.5 Timer Mode Register 3: The description of the LWA and PHCKSEL bits, modified
		738	19.2.9 Timer Status Register: The body, corrected (MUT5 → MTU5); bit table: The "Description" column for b5 (TCFU), modified (description in relation with MTU8, deleted)
		740	19.2.9 Timer Status Register: TCFU Flag: the body, modified (description in relation with MTU8, deleted)
		744	19.2.13 Timer Counter: The body, modified; MTU8.TCNT: A note, added
		745	19.2.15 Timer General Register: Note to bit map for MTU8.TGRA, TGRB, TGRC, TGRD, added
		756	19.2.22 Timer Output Control Registers 1: The body, modified; bit table: b3 (TOCL): Note 4, added
		757	Figure 19.3 Example of Output in Complementary PWM Mode: Item names on Y axis, modified ("Positive phase output" → "Positive phase output (MTIOC4A)", "Negative phase output" → "Negative phase output (MTIOC4C)")
		762	19.2.25 Timer Gate Control Register A: Bit table: b0 (UF), b1 (VF), b2 (WF): The "Description" colum, modified (TGCR.FB → TGCRA.FB)
		788	Figure 19.7 Periodic Counter Operation: Item name on the chart, modified ("TCIV interrupt signal" → "TGI interrupt signal")
		789	19.3.1, (2) Waveform Output by Compare Match: The body, modified
		789	Figure 19.8 Example of Procedure for Setting Waveform Output by Compare Match: Step [3], modified
		791	19.3.1, (3) Input Capture Function: The body, modified (the MTIC5U, MTIC5V, and MTIC5W pins, added)
		793	19.3.2 Synchronous Operation: The description regarding MTU8, added
		800	19.3.4 Cascaded Operation: The body, modified ("when the MTU1.TMDR3.LWA bit is set to 0" → "when the MTU1.TMDR3.LWA bit is set to 1")
		809	Figure 19.29 Examples of PWM Mode Operation (PWM Waveform Output with 0% Duty and 100% Duty) (n = 0 to 4, 6, or 7): Case titles [1] to [3], added
		810	19.3.6 Phase Counting Mode: One of the registers in 32-bit phase counting mode, modified (TGR → TMDR1)
		810	Figure 19.30 Example of Phase Counting Mode Setting Procedure: Expression, modified ("A- or B-phase input signal" → "A- or B-phase input pin")
		821	19.3.6, (4) 32-bit Phase Counting Mode Application Example: The body, modified One of the registers in cascade connection 32-bit phase counting mode, modified (TGR → TMDR1) "(MTU1.TGRALW, MTU1.TGRBLW)" added to the general register
		823	Figure 19.43 Procedure of Selecting 32-bit Phase Counting Mode: Throughout the steps, the letter "b"s for binary notation, added; Note, modified (TMDR → TMDR1)
		825	Figure 19.44 Procedure for Selecting Reset-Synchronized PWM Mode: Step [5], modified, box [9], modified
		835	Figure 19.50 Example of Operation in Complementary PWM Mode (MTU3 and MTU4): Items on the chart, modified ("Positive-phase output" → "Positive-phase output (MTIOC4A)", "Negative-phase output" → "Negative-phase output (MTIOC4C)")
		853, 854	Figure 19.68 to Figure 19.71: The title, modified ("TWCRB" deleted)
		859	Figure 19.78 Example of Counter Clearing Operation by MTU3.TGRA Compare Match: Items on the chart, modified ("Output waveform" → "Positive-phase output", "Output waveform#" → "Negative-phase output")
		873	Figure 19.93 Basic Example of A/D Converter Start Request Signal (TRG4AN) Operation: Legends MTU4.TADCORA and MTU4.TADCOBRA, relocated
		874	Figure 19.94 Example of A/D Converter Start Request Signal (TRG4AN) and Buffer Transfer Operation: Legends MTU4.TADCORA and MTU4.TADCOBRA, relocated
		908	19.6.12 Contention between MTU2.TCNT Write Operation and Overflow/Underflow in Cascaded Operation: Erroneous descriptions corrected (write cycle → writing)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	913	19.6.20 Output Level in Complementary PWM Mode and Reset-Synchronized PWM Mode: Bit names, modified (TDER.TDER→TDERA.TDER (TDERB.TDER), TOCR1.OLSN → TOCR1A.OLSN (TOCR1B.OLSN), TOCR1.OLSP → TOCR1A.OLSP (TOCR1B.OLSP))
		915	19.6.25 Points for Caution to Prevent Malfunctions in Synchronous Clearing for Complementary PWM Mode: Erroneous description on the body, corrected
		949	19.8.2, (3) Clear Counting Operation: The title and body, modified
		20. Port Output Enable 3 (POE3)	
		953	20.2.1 Input Level Control/Status Register 1 (ICSR1): The body, modified (POE0# to POE3# pins → POE0# pin)
		954	20.2.2 Input Level Control/Status Register 2: The bit name for PIE2, modified
		957	20.2.5 Input Level Control/Status Register 5 (ICSR5): Note, modified; [Clearing condition] for the POE10F flag (POE10 flag), modified (POE11F → POE10F)
		958	20.2.6 Input Level Control/Status Register 6: OSTSTF flag, the body, modified
		962	20.2.9 Active Level Setting Register 1: OLSEN bit, the body, modified (the range covered by the index m, added)
		964	20.2.10 Software Port Output Enable Register: GPT3HIZ Bit, erroneous descriptions corrected (GPT23HIZ → GPT3HIZ)
		980	Table 20.4 Target Pins and Conditions for High-Impedance Control (2 / 2): Detailed conditions for the GPT3 pins, modified
		982	Table 20.5 Correspondence between MTU and GPT Pins: Note 2, modified
		21. General PWM Timer (GPTa)	
		All	The expressions related to restarting a counter, modified to those meaning clearing of a counter; representation of the letter n, modified (channel number → 0 to 3)
		988	Table 21.1 Specifications of GPT: Event counting, deleted; description in relation with transition to module-stop state, added
		990	Table 21.2 Functions of GPT (2 / 2): The item "Setting module-stop state", added
		991	Figure 21.1 Block Diagram of GPT: The register names of GTHPSR, GTCNT, GTDVU, GTDVD, GTDBU, GTDBD, modified
		1005, 1006	21.2.12 General PWM Timer I/O Control Register: OAHLD bit, OBHLD bit: The body, modified
		1023	21.2.29 General PWM Timer Dead Time Value Register m: Address(es): GPT1.GTDVU, modified
		1036	Figure 21.13 Example of GTPR Buffer Operation (Saw Waves in Up-Count Operation): Example operation of GTPBR, "dddd" added as a buffer content
		1038	Figure 21.15 Example for Setting GTPR Buffer Operation: Figure 21.14, deleted
		1100	21.6.2, (1) Start Counting: The title and description, modified
		1101	21.6.2, (3) Clear Counting: The title and description, modified
		1115	21.8.1 Pin Settings after Reset: The body, modified
		22. 16-Bit Timer Pulse Unit (TPUa)	
		All	The expressions related to restarting a counter, modified to those meaning clearing of a counter
		1118	Table 22.1 Specifications of TPU: Pulse input/output, settable operations, and interrupt source: "× 2 units", added
		1119	Table 22.2 TPU (Unit 0) Functions (1 / 2): DMAC activation: TGRB added as the target register
		1119, 1120	Table 22.2 TPU (Unit 0) Functions: Module-stop setting: Erroneous bit name, corrected; note 1, added (former notes 1 and 2 renumbered as notes 2 and 3)
		1120, 1121	Table 22.3 TPU (Unit 1) Functions: Module-stop setting: Erroneous bit name, corrected; note 1, added (former note 1 renumbered as note 2)
		1142	22.2.4 Timer Interrupt Enable Register: Bit table: Note 3, added
		1150	22.2.10 Noise Filter Control Register: Note 1, modified
		1152	22.2.11 PWM Feedback Select Register: Bit table: b4 to b2 (FBSL0[2:0]), R/W, added
		1153	Figure 22.3 PWM Feedback Setting and TPU Input Capture Configuration (Example of Unit 0): Interrupt source modules, corrected (GPU0 to GPU2 → GPT0 to GPT2)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1157	Figure 22.7 Example of Setting Procedure for Waveform Output by Compare Match: A suffix shown in the figure, modified (n → m)
		1167	22.3.4 Cascaded Operation: Erroneous suffix, corrected (TPUm.TCNT (n = 2, 5) → TPUn.TCNT (n = 2, 5); note 3, added
		1169	22.3.5 PWM Modes: The description, partially relocated; the paragraphs titled "1. PWM mode 1" and "2. PWM mode 2": The body, modified
		1173	Figure 22.25 Example of PWM Mode Operation (3): Case titels (a) to (c) and descriptions for each case, added
		1179	22.3.6.1 Phase Counting Mode Application Example: The body, modified
		1180	22.3.7 Noise Filters: The description in relation with the sampling condition, modified
		1181	22.3.8.1 Example Setting of PWM 1-Axis Measurement (TPU (Unit 0) is Set as the Internal PWM Feedback Input): The body, modified
		1182	Figure 22.33 Connection Diagram of Example Setting for PWM 1-Axis Measurement: Suffix m for TGRA and TGRB, deleted
		1183	22.3.8.2 Example Setting of PWM 2-Axes Measurement (TPU (Unit 0) is Set as the Internal PWM Feedback Input): The body, modified
		1184	Figure 22.34 Connection Diagram of Example Setting for PWM 2-Axes Measurement: Suffix m for TGRA and TGRB, deleted
		1185	22.3.8.3 Example Setting of PWM 1-Axis Measurement (TPU (Unit 0) Is Set as the Input Capture Function): The body, modified
		1186	Figure 22.35 Connection Diagram of Example Setting for PWM 1-Axis Measurement: Suffix m for TGRA and TGRB, deleted
		1187	22.3.8.4 Example Setting of PWM 2-Axes Measurement (TPU (Unit 0, Unit 1) Is Set as the Input Capture Function): The body, modified
		1188	Figure 22.36 Connection Diagram of Example Setting for PWM 2-Axes Measurement: Suffix m for TGRA and TGRB, deleted
		1191	22.4, (3) Underflow Interrupt: The number of interrupts, modified
		1191	22.5 DMAC Activation: The TPUm.TGRB register, added; the number of input capture/compare match interrupts, modified
		1193	Figure 22.40 Input Capture Signal Timing: The timing lines showing a rise on the input capture signal, modified
		1201	Figure 22.54 Conflict between Reading from the TPUm.TGRy Register and Input Capture: Notation in the figure, modified (buffer register → TPUm.TGRy register)
		1202	Figure 22.55 Conflict between Writing to the TPUm.TGRy Register and Input Capture: Notation in the figure, modified (TPUm.TCNT → TPUm.TGRy)
		1208	Table 22.32 Ability of Interrupt Sources to Serve as Event Signals for Transmission to the ELC: Channels 4 and 5, deleted; note 2, modified
		1208	22.10.2, (1) Start Counting: A sentence "by the ELOPF register of the ELC", added
		1209	22.10.2, (2) Clear Counting: The title and body, modified
		1209	Figure 22.63 Restart Counting on Reception of the Event Signal: Explanation added to the timing chart
		1210	22.10.2, (3) Input Capture Operation: The body, modified
		1211	22.10.3, (2) Clear Counting: The body, modified
		23. Programmable Pulse Generator (PPG)	
		1215	Table 23.2 Functions of the PPG: Symbols of the MTU3a and TPUa modules, modified
		1216	Figure 23.1 Block Diagram of PPG: Alternative group names added to each block for pulse output pins (groups 7 to 4)
		1220	23.2.3 Output Data Registers H (PODRH)/Output Data Registers L (PODRL): The body, modified
		1222	23.2.4 Next Data Registers H (NDRH), Next Data Registers L (NDRL): Address(es): Register symbols added
		1222, 1223	23.2.4, NDRH: (1), bullet items, modified; note 1, modified; (2), bullet items, modified

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1223, 1224	23.2.4, NDRL: (1), bullet items, modified; note 1, modified; (2), bullet items, modified
		1225	23.2.5 PPG Output Control Register: The body, modified
		1227	23.2.6 PPG Output Mode Register: The body, modified
		1230	23.3 Operation: The body, modified
		1233	23.3.3 Example of Normal Pulse Output (Example of Five-Phase Pulse Output): The body, steps 1 to 4, modified
		1234	23.3.4 Non-Overlapping Pulse Output: The suffix for TGIA, modified (TGIAn → TGIAm (m = 0 to 3))
		1236, 1237	23.3.6 Example of Non-Overlapping Pulse Output (Example of Four-Phase Complementary Non-Overlapping Output): The body, steps 1 to 4, modified
		1239	23.3.8 Pulse Output Triggered by Input Capture: The body, modified
		24. Compare Match Timer (CMT)	
		All	Register symbols, modified (CMCNT0 → CMT0.CMCNT, CMCNT1 → CMT1.CMCNT, CMCNT2 → CMT2.CMCNT, CMCNT3 → CMT3.CMCNT, CMCNT4 → CMT4.CMCNT, CMCNT5 → CMT5.CMCNT, CMCOR0 → CMT0.CMCOR, CMCOR1 → CMT1.CMCOR, CMCOR2 → CMT2.CMCOR, CMCOR3 → CMT3.CMCOR, CMCOR4 → CMT4.CMCOR, CMCOR5 → CMT5.CMCOR)
		1240	Table 24.1 CMT Specifications: Event link function: The explanation supplemented ("only channel 1" → "only channel 1 of unit 0)
		1243	24.2.4 Compare Match Timer Control Register: b1, b0 (CKS[1:0]): The "Description" column, modified (CMCNTn counter → CMTn.CMCNT counter, CMSTR.STRn bit → CMSTRm.STRn bit); the description for suffix "m", added
		1244	24.2.5 Compare Match Timer Counter: Register symbol, modified (CMSTRn.STRm → CMSTRm.STRn); the description for suffixes "m" and "n", modified
		1245	24.3.1 Periodic Count Operation: Register symbol, modified (CMSTRn.STRm → CMSTRm.STRn)
		1247	24.5.1 Event Issuance to ELC: Register symbol, modified (CMCSRn.CMIE → CMT1.CMCR.CMIE)
		1248	24.5.2, (1) Count Start: Register-bit name, modified
		1248	Figure 24.6 Count Start Operation at Reception of an Event: Items on the chart, modified ("function select n" → "operation select", "Event input signal n" → " Event input signal", CMSTR.STRn → CMSTR0.STR1, CMCNTn → CMT1.CMCNT)
		1249	24.5.2, (2) Event Count: Register symbol and name, modified
		1249	Figure 24.7 Event Count Operation at Reception of an Event: Items on the chart, modified ("function select n" → "operation select", "Event input signal n" → " Event input signal", CMCNTn → CMT1.CMCNT)
		1250	24.5.2, (3) Count Clear: The body, modified; register symbol and name, modified
		1250	Figure 24.8 Count Clear Operation at Reception of an Event: Items on the chart, modified ("function select n" → "operation select", "Event input signal n" → " Event input signal", CMCNTn → CMT1.CMCNT)
		1251	Figure 24.9 Conflict between Event Reception and Register Access at Count Start Operation: Items on the chart, modified ("function select m" → "operation select", "Event input signal m" → " Event input signal", CMSTRn.STRm → CMSTR0.STR1)
		1252	Figure 24.10 Conflict between Event Reception and Register Access at Event Count Operation: Items on the chart, modified ("function select" → "operation select", CMCNT → CMT1.CMCNT)
		1253	Figure 24.11 Conflict between Event Reception and Register Access at Count Clear Operation: Items on the chart, modified ("function select" → "operation select", CMCNT → CMT1.CMCNT)
		1255	Table 24.3 Summary of Conflicted Operations among Event Link Operation, Register Access, and Counter Status: Register-bit name, modified (CMSTRn.STRm → CMSTR0.STR1)
		25. Compare Match Timer W (CMTW)	
		All	The expressions related to restarting a counter, modified to those meaning clearing of a counter
		1256	Table 25.1 Specifications of CMTW: Event link: Erroneous description, corrected

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1257	Figure 25.1 Block Diagram of CMTW (Unit 0): The title, modified; erroneous register symbols, corrected; interrupt request signals, modified
		1259	25.2.2 Timer Control Register: Bit table: b6 (OC0IE), b7 (OC1IE): The "Description" column, modified (output capture → output compare)
		1274	Figure 25.9 Count Timing (PCLKD/8): Data name "N-1" added to CMWCNT
		1276	25.3.9 Digital Noise Filtering: The description in relation with the sampling condition, modified
		1277	25.4.1 CMTW Interrupt Sources and DMAC Transfer Requests and Table 25.3 CMTW Interrupt Sources: Suffix n added to the individual interrupt source names
		1280	25.5.2 Actions on Acceptance of Event Signals from ELC: The body, the error, corrected (four actions → three actions)
		1281	25.5.2, (3) Clear a Counter: The body, modified
		1282	25.6.1 Module-Stop Function: The body, modified
		1287	25.6.8, (4) Input Capture Operation, deleted
		1287	25.6.8, Figure 25.29 Contention between Counter Clearing on Event Acceptance and Register Access in Input Capture Operation, deleted
		1288	Table 25.4 Summary of Contention between Operations Due to the Event Link, Access to Registers, and Changes to the Counter's State: Register symbols modified; the item "Input Capture", deleted
		26. Watchdog Timer (WDTA)	
		1289	Table 26.1 WDT Specifications: Number of internal channels, modified; event link function, deleted
		1290	Figure 26.1 WDT Block Diagram: The block for the WDTRCR register, added; the arrow representing event link output and the block for event link controller circuit, deleted
		1296	26.2.3 WDT Status Register: The body, modified
		1299	Figure 26.3 Operation Example in Register Start Mode: Explanation of error notification to ECM, modified (Active: L → Active: H)
		1300	26.3.2 Control over Writing to the WDTCR and WDTRCR Registers: The body, modified
		1304	26.4.1 Watchdog Timer Operation during Low-Power Consumption Mode Transition: The body, modified (Coretex-R4, Coretex-M3 → Cortex-R4, Cortex-M3)
		1304	Table 26.4 WDT Operation in Transition between Low-Power Consumption Modes <in Low-Power Consumption Mode Transition>: The column of VDD, deleted
		1304	26.5 Link Operation by the Event Link (ELC) Function, deleted
		27. Independent Watchdog Timer (IWDTa)	
		1305	Table 27.1 IWDT Specifications: Event link function, deleted
		1306	Figure 27.1 IWDT Block Diagram: The block for the IWDTRCR register, added; the arrow representing event link output and the block for event link controller circuit, deleted
		1312	27.2.3 IWDT Status Register: The body, modified
		1315	Figure 27.3 Operation Example in Register Start Mode: Explanation of error notification to ECM, modified (Active: L → Active: H)
		1316	27.3.2 Control Over Writing to the IWDTCR and IWDTRCR Registers: The body, modified
		1321	27.3.6 Reading the Down-Counter Value: The body, modified
		1321	Figure 27.7 Processing for Reading IWDT Counter Value (IWDTCR.CKS[3:0] = 0000b, IWDTCR.TOPS[1:0] = 11b), modified (replaced)
		—	Figure 27.8 Processing for Reading IWDT Counter Value (IWDTCR.CKS[3:0] = 0010b, IWDTCR.TOPS[1:0] = 11b), deleted
		1322	27.4.1 Watchdog Timer Operation during Low-Power Consumption Mode Transition: The body, modified (Coretex-R4, Coretex-M3 → Cortex-R4, Cortex-M3)
		1322	Table 27.4 IWDT Operation in Transition to Low-Power Consumption Modes <Low-Power Consumption Mode Transition>: The column of VDD, deleted
		1322	27.5 Usage Notes, deleted
		1322	27.6 Link Operation by the Event Link (ELC) Function, deleted

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	28. Ethernet MAC (ETHERC)	
		1323	Table 28.1 ETHERC Specifications: Note 1, added
		1325	Table 28.2 Input/Output Pins of the ETHERC: The ETH0_RXC, ETH1_RXC, and ETH2_RXC pins: The "I/O" and "Description" columns, modified
		1326	Table 28.3 I/O Pin Functions for ETHERC: Pin description, modified (reception clock input/output pin → reception clock input pin)
		1327	28.2.1.1 System Protect Command Register: Address(es): The address for access from the Cortex-M3, deleted
		1328	28.2.1.2 Ethernet MAC Reset Register: Address(es): The address for access from the Cortex-M3, deleted
		1331	28.2.1.5 MII Control Register: Bit table: Note 1, added
		1333	28.2.2.1 MIIM Register: Address(es): The address for access from the Cortex-M3, deleted; bit table: The "Description" column for b26 (RWDV), modified
		1334	28.2.2.2 TX ID Register: Address(es): The address for access from the Cortex-M3, deleted
		1335	28.2.2.3 TX RESULT Register: Address(es): The address for access from the Cortex-M3, deleted; bit table: The "Description" column for b8(CSERR), b11(TFAIL), modified
		1336	28.2.2.4 MODE Register: Address(es): The address for access from the Cortex-M3, deleted
		1337	28.2.2.5 RX MODE Register: Address(es): The address for access from the Cortex-M3, deleted
		1339, 1340	28.2.2.6 TX MODE Register: Address(es): The address for access from the Cortex-M3, deleted; b15 and b14, the bit function, modified (FSTTH[1:0] → reserved); bit table: The functional description when b29 (SF) = 1, modified; note 1, modified
		1341	28.2.2.7 RESET Register: Address(es): The address for access from the Cortex-M3, deleted, bit table: b14 (reserved bit), added
		1342, 1343	28.2.2.8 PAUSE Packet Data Register: Addresses of the GMAC_PAUSE1 to GMAC_PAUSE5 registers: The addresses for access from the Cortex-M3, deleted
		1344	28.2.2.9 RX FLOW CONTROL Register: Address(es): The address for access from the Cortex-M3, deleted
		1344	28.2.2.10 PAUSE Packet Register: Address(es): The address for access from the Cortex-M3, deleted
		1345, 1346	28.2.2.11 MAC Address Registers: Addresses of the GMAC_ADRnA and GMAC_ADRnB registers: The addresses for access from the Cortex-M3, deleted
		1347	28.2.2.12 RX FIFO Status Register: Address(es): The address for access from the Cortex-M3, deleted
		1348	28.2.2.13 TX FIFO Status Register: Address(es): The address for access from the Cortex-M3, deleted
		1349	28.2.2.14 TCPIPACC Register: Address(es): The address for access from the Cortex-M3, deleted
		1350	28.2.2.15 RX MAC ENABLE Register: Address(es): The address for access from the Cortex-M3, deleted
		1350	28.2.2.16 LPI Mode Control Register: Address(es): The address for access from the Cortex-M3, deleted
		1351	28.2.2.17 LPI CLIENT Timing Control Register: Address(es): The address for access from the Cortex-M3, deleted
		1352	28.2.2.18 Reception Buffer Information Register: Address(es): The address for access from the Cortex-M3, deleted, the functional description of the ADDR[15:0] bits, modified
		1353	28.2.3.1 Hardware Function System Call Register: The address for access from the Cortex-M3, deleted
		1354, 1355	28.2.3.2 Hardware Function Argument Register: Addresses of the R4 to R7 registers: The addresses for access from the Cortex-M3, deleted
		1357	28.2.3.4 Hardware Function Return Value Register: Addresses of the R0 and R1 registers: The addresses for access from the Cortex-M3, deleted
		1363	28.3.1.3, (2) Buffer Control Operation, (a) Acquisition of buffers (HWFNC_ShortBuffer_Get, HWFNC_LongBuffer_Get): The description, modified (a segment boundary → a segment boundary (128 bytes))

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1364	28.3.1.3, (2) Buffer Control Operation, (b) Releasing whole area of a buffer (HWFNC_Buffer_Release): Section title, modified
		1367	Table 28.10 HWFNC_Buffer_Return: The "Function" column, modified (as any byte → at byte boundaries)
		1368	Figure 28.8 Block Diagram of the MACDMAC in context and Interrupt Signals: The names of the interrupt signals, modified
		1375	Table 28.13 HWFNC_MACDMA_RX_Control: Note 1, added
		1376	28.3.1.4, (3) DMA for the transmission MAC, (a) Usage: The body, modified
		1379	28.3.1.5, (1) Functional Overview: The body, modified
		1386	Figure 28.14 Transmission Frame Control Information: A note, added
		1387	28.3.3.2, (2) Ethernet frame, (a) When the transmission TCPIP accelerator is enabled: The note, modified
		1389	28.3.3.3 Creating transmit descriptors: The body, modified; figure 28.19 Transmit Descriptor Configuration, deleted
		1408	28.4.7 Frame with Size Exceeding 1518 Bytes, added
		1408	28.4.8 Use of Hardware Real-Time OS, added
		29. Ethernet Switch	
		1409	Table 29.1 Ethernet Switch Specifications: The "Desciption" colum modified (IEEE802.1q → IEEE802.1Q)
		1409	29.1 Overview: Figures for reference, added
		1412	29.2.1.1 Ethernet PHY LINK Mode Register: Bit table: The "Description" column for b0 (SWLINK0), modified (LINK0 signal → PHYLINK0 signal); the "Description" column for b1 (SWLINK1), modified (LINK1 signal → PHYLINK1 signal)
		1422	29.2.2.7 Mode Configuration Register: Bit table, modified b30 to b1 (reserved) → b30 to b0 (reserved))
		1426	29.2.2.11 Output Queue Minimum Memory Statistics Register: Bit table, modified (b31 to b13 (reserved) → b31 to b5 (reserved))
		1428	29.2.2.13 Internal Queue Interface Status Register: Bit table: The "Description" column for b16 (P0RXFIFOAV), b17 (P1RXFIFOAV), and b18 (P2RXFIFOAV), modified (TX FIFO → RX FIFO)
		1429	29.2.2.14 Queue Weight Register: Bit table, modified (b31 to b19 (reserved) → b31 to b29 (reserved))
		1431	29.2.2.16 IP Priority Register n: Bit table: The "Bit Name" column for b8 (IPV6SELECT), modified; the "Bit Name" and "Description" columns for b31 (READ), modified
		1436	29.2.2.21 MAC Address High Register For Hub Input Filter: Bit table: The "Description" column for b15 to b8 (MACADD6n), modified
		1457	29.2.5.10 Timer Increment Register: Bit table: The register name in the "Description" column for b22 to b16 (OFFSCORRINC), modified
		1464	29.2.6.1 DLR Control Register: Bit table: The "Description" column for b15 to b8 (CYCMCLK), modified ("4b" → "4Bh")
		1477	29.2.6.17 DLR MAC Statistics Counters: The description of the suffix "m" shown in the table, added
		1482	Figure 29.8 Record Types of Address Table: Static record, the name of bits 52 to 50, added
		1505	29.3.4.3, (5) Offset Correction: The erroneous register symbol in the body, corrected (ATIME_CORR_OFFS → ATIME_OFFS_CORR)
		30. EtherCAT Slave Controller (optional)	
		1518	Table 30.2 Input/Output Pins of the EtherCAT Slave Controller (excluding PHY MII pins): The "Function" column: Output, input or I/O was added to each pin.
		1531	30.6.3 ESC Write Enable Register: Bit table: The "Description" column for b0 (ENABLE), modified (ESC_WR_PROTECT, at 0021h → ESC_WR_PROTECT, at 0031h)
		1548	30.10.4 AL Event Request Register: Bit table: The "Description" column for b2 (DCSYNC0STA), modified (DC_SYNC_STAT0 → DC_SYNC0_STAT); the "Description" column for b3 (DCSYNC1STA), modified (DC_SYNC_STAT1 → DC_SYNC1_STAT)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1556	30.13.2 EEPROM PDI Access State Register: Bit table: The erroneous symbol of b0, corrected (PDIACCEES → PDIACCESS)
		1557	30.13.3 EEPROM Control/Status Register: Bit table: Note 1 and note 2, modified (the prefix "b" indicating a bit, added)
		1562	30.14.6 MII Management PDI Access State Register: Bit table: The description for settings 1 and 0 in the "Description" column for b1 (FORPDI), modified
		1581	30.17.4.1 Activation Register: Bit table: The erroneous description for settings 1 and 0 in the "Description" column for b6 (NEARFUTURE), corrected
		31. USB2.0HS Host Module (USBh)	
		1601	31.1 Overview: The body, modified (the port connection path select register (P1PORTSEL) → the port connection path select input signal bits (PHYSET1.P1PORTSEL[1:0]))
		1602	31.1, (3) AHB-PCI Bridge: The description, modified
		1605	Table 31.1 Register Mapping List (1 / 2): The register name of A004 0044h, modified (HcLSThreshold → Reserved)
		1617, 1618	31.3.1.6 HcInterruptDisable Register: Bit table: The "Description" column, modified (delete → disable)
		1625	31.3.1.18 HcLSThreshold Register, deleted
		1639	31.3.2.5 USBCMD Register: Bit table: The "Symbol" column for b5 and b11, modified
		1642	31.3.2.6 USBSTS Register: Bit table: The "Description" column for b15 (Asynchronous Schedule Status), modified (bit 5 (Asynchronous Schedule Enable) → bit 5 (ASPME))
		1652	31.3.3.2 Offset 04h Register: Bit map: Erroneous bit symbol of b7, corrected (Wait Cycle → Wait Cycle Control)
		1655	31.3.3.4 Offset 0Ch Register: Address(es), modified
		1684	31.3.6.4 PCI_INT_ENABLE Register: Address(es), modified; bit table: The erroneous symbols and bit names of b0, b1, and b2, corrected
		1709	Figure 31.13 Initial Setting Sequence: The error, corrected (PRCP→PRCR)
		32. USB 2.0 HS Function Module (USBf)	
		1712	32.1 Overview: The body, modified (the port connection path select register (P1PORTSEL) → the port connection path select input signal bits (PHYSET1.P1PORTSEL[1:0]))
		1720	32.2.2.1 Device State Control Register 0: Bit table: b8 (WKUP), the "H/W" column, modified
		1729	32.2.5.3 D0FIFO Port Select Register, D1FIFO Port Select Register: Address(es): Erroneous register symbol, corrected
		1741	32.2.8.1 Interrupt Status Register 0: The description of the resume interrupt status bit, modified (the suffix "b" indicating a binary number, added)
		1752	32.2.11.1 USB Request Type Register: The erroneous bit name and symbols in the description of the USB request type bits and USB request bits, corrected
		1759	32.2.12.2 DCP Control Register (DCPCTR): Erroneous description in the clear bit of sequence toggle bit (SQCLR), corrected (DATA1 → DATA0)
		1760	32.2.13.1 Pipe Window Select Register: Bit table: The suffix "b" indicating a binary number was added to the setting in note 1; the erroneous setting in the description of the pipe window select bits, corrected
		1761, 1764	32.2.13.2 Pipe Configuration Register: Bit map: The erroneous symbols for b15 and b14, modified; the description of the transfer type bits, modified
		1767	32.2.13.4 Pipe Maximum Packet Size Register: The description of the maximum packet size bits, modified
		1773	32.2.14.1 PIPE1 Control Register, PIPE2 Control Register, PIPE3 Control Register, PIPE4 Control Register, PIPE5 Control Register: The description of the response PID bits, modified
		1779	32.2.14.2 PIPE6 Control Register, PIPE7 Control Register, PIPE8 Control Register, PIPE9 Control Register: The description of the auto buffer clear mode bit, modified
		1782, 1783	32.2.15.2 PIPE1 Transaction Counter Register, PIPE2 Transaction Counter Register, PIPE3 Transaction Counter Register, PIPE4 Transaction Counter Register, PIPE5 Transaction Counter Register: Erroneous bit symbols in the description of the transaction counter bits, corrected

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1784	Table 32.18 List of Registers that can be Written by Software when SUSPM = 0: A006 0140h (BCCTRL), deleted
		1785	32.2.17.1 D0FIFO Continuous Transfer Port Register n, D1FIFO Continuous Transfer Port Register n: The suffix "b" indicating a binary number was added to the setting in the description of the FIFO port control
		1788	Table 32.19 Types of Reset: The entry "Hardware reset", deleted
		1793	32.4.3 Control Transfer Stage Transition Interrupt: The body, modified (the suffix "b" indicating a binary number, added)
		1797	32.5.3 Pipe Control Register Switching Procedures: The body, modified (the description of the DEVADDx register and CSCLR bit, deleted)
		1797	Figure 32.9 Procedure for Changing Pipe Information from USB Transmission Enabled (PID = BUF) State: Processing "Wait until CSSTS bit of the current pipe changes to 0", deleted
		1804	32.8.4 Control Transfer Automatic Response: The erroneous description in (1), corrected
		1804	Table 32.29 List of Responses to Received Tokens: Note numbers, modified
		1810	32.12 SOF Interpolation: The body, erroneous bit names, corrected (SCKE bit and SCKE bit → the USBE and SUSPM bits)
		33. Serial Communications Interface with FIFO (SCIFA)	
		1811	Table 33.1 Specifications of SCIFA: The description in the "Interrupt source" entry and "Receive error detection" in the "Asynchronous communication mode" entry, modified
		1812 to 1864	33. Serial Communications Interface with FIFO (SCIFA): Throughout this section, interrupt names are modified ("F" added to the end)
		1813	33.2.1 Receive Shift Register: The body, modified
		1813	33.2.2 Receive FIFO Data Register: The description, added
		1820	33.2.7 Serial Status Register: The description of the TEND bit, modified
		1822	Table 33.3 SMR Register Setting: Table heading, modified (SMR Register Settings → Setting of SMR.CKS [1:0] Bits, CKS1 → b1, and CKS0 → b0)
		1826	33.2.9 Modulation Duty Register: MDDR register setting, modified (128 ≤ MDDR ≤ 256 → 128 ≤ MDDR ≤ 255)
		1826	Table 33.10 Bit Rates and BRR and MDDR Registers Settings in Asynchronous Mode: The combinations shown in the table were modified to those with which the minimum errors are obtained.
		1828	33.2.10 FIFO Control Register: The description of the TTRG[1:0], RTRG[1:0], and RSTRG[2:0] bits, modified
		1829	33.2.11 FIFO Data Count Register: The body, modified
		1830, 1831	33.2.12 Serial Port Register: The description, modified (the multi-port controller (MPC) → the multi-function pin controller (MPC))
		1836	33.3.1 Overview: The body, modified
		1837	Table 33.15 SMR, SCR, and SPTR Register Settings and SCIFA Clock Source Selection: Table heading, modified (CKE1, CKE0 → CKE[1:0])
		1841	Figure 33.3 Sample Flowchart for SCIFA Initialization in Asynchronous Mode: The processing, modified
		1844	Figure 33.7 Sample Flowchart for Receiving Serial Data in Asynchronous Mode (1): The description, modified (the receive FIFO threshold → the receive data trigger number); the erroneous register name, corrected
		1847	Figure 33.10 Example of SCIFA Receive Operation in Asynchronous Mode Using Model Control Function (RTS#): Pin name, modified (RTSn pin → RTS# pin)
		1849	Figure 33.12 Sample Flowchart for SCIFA Initialization in Clock Synchronous Mode: The processing, modified
		1852	Figure 33.15 Sample Flowchart for Receiving Serial Data in Clock Synchronous Mode: The description, modified (the receive FIFO threshold → the receive data trigger number)
		1854	Figure 33.17 Sample Flowchart for Simultaneous Transmitting/Receiving Serial Data in Clock Synchronous Mode: Note 1, modified (the receive FIFO threshold → the receive data trigger number)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	1855	33.4 Bit Modulation: The bit symbol, modified
		1856	33.5 Interrupt Sources: The body, modified
		1862	33.8.11 Notes on Initialization of the SCIFA, added
		34. I^2C Bus Interface (RIICa)	
		1863	Table 34.1 RIIC Specifications (1/2): The description in the "Arbitration" entry, modified
		1873	34.2.4 I^2C Bus Mode Register 2: The body, modified (SDA output delay function, added); the address(es), unnecessary address, deleted
		1875, 1876	34.2.5 I^2C Bus Mode Register 3: The body, modified (the setting for acknowledgement, added); the description of the ACKBR, ACKBT, and RDRFS bits, modified"
		1877, 1878	34.2.6 I^2C Bus Function Enable Register: The description of the MALE, NALE, SALE, and SCLE bits, modified
		1882, 1883	34.2.9 I^2C Bus Status Register 1: Throughout the section, the description corrected (device ID → device-ID address)
		1884	34.2.10 I^2C Bus Status Register 2: The description of the AL flag, modified (NACK arbitration-lost detection → NACK transmission arbitration-lost detection)
		1897	34.3.3 Master Transmit Operation: Erroneous register name in step (6), corrected (ICCR2 → ICSR2)
		1898	Figure 34.6 Example of Master Transmission Flowchart: The description in [6], modified
		1901	34.3.4 Master Receive Operation: The body: Description regarding the examples of usage of master reception, added; Step (5): Erroneous description, corrected (rising edge → falling edge)
		1902	Figure 34.10 Example of Master Reception (7-Bit Address Format, 1 or 2 bytes): The description in (8), modified; the erroneous register symbol, corrected
		1903	Figure 34.11 Example of Master Reception (7-Bit Address Format, 3 Bytes or More): The description in [8], modified
		1906	34.3.5 Slave Transmit Operation: The description in (1) and (2), modified; the erroneous flag name in (3), corrected (TEND → TDRE)
		1908	Figure 34.17 Slave Transmit Operation Timing (2): The description the flow shown as [5] in Figure 34.15, added
		1909	34.3.6 Slave Receive Operation: The description in (1), (3), and (4), modified
		1915	Figure 34.24 AASy Flag Set Timing with 7-Bit Address Format Selected: The description for the case of "[7-bit address format: Slave reception]", added
		1916	Figure 34.25 AASy Flag Set Timing with 10-Bit Address Format Selected: The description for the case of "[10-bit address format: Slave reception]", added
		1917	Figure 34.26 AASy Flag Set/Clear Timing with 7-Bit/10-Bit Address Formats Mixed: The position of "Address mismatch", modified; the erroneous register symbols, corrected
		1929	Figure 34.36 Start Condition/Restart Condition Issue Timing (ST and RS Bits): The high-level period of SCLn line in the timing chart for the case of "[Restart condition issuing operation]", modified (8 → 9)
		1932	Figure 34.38 Timeout Function (TMOE, TMOS, TMOH, and TMOL Bits): The erroneous settings of TMOS bit in the timing chart for the case of "[Example of operation when TMOH = 1 and TMOL = 1]", corrected
		35. CAN Interface (RSCAN)	
		1947	35.2.2 Channel Control Registers: BOM[1:0] bits: The values indicated by suffix "m" of RSCAN0CmCTR, corrected
		1951	35.2.4 Channel Error Flag Registers: The body, modified
		1952	35.2.4 Channel Error Flag Registers: BOEF flag: The values indicated by suffix "m" of RSCAN0CmCTR, corrected
		1960	35.2.9 Global TX Interrupt Status Register 0: Bit table: b1 (TAIF0) and b9 (TAIF1): Bit names, corrected; the interrupt name in the "Description" column, corrected
		1963	35.2.11 Reception Rule Entry Control Register: Bit table: The range of pages in the "Description" column for b4 to b0 (AFLPN [4:0]), modified; the description of the AFLPN[4:0] bits, modified
		2000	35.2.38 FIFO Full Status Register: Bit table: b31 to b14 (reserved): Access attribution, modified (R → R(W))

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	2029	35.2.62 Global Test Control Register: The description of the RTME bit, modified
		2034	Table 35.11 ECERVF and ECTHM Bits and Error Detection Setting: Table headings, corrected (Two bits are switched)
		2039	Figure 35.3 CAN Channel Interrupt Block Diagram: Register names, modified (suffix "m" added)
		2048	Figure 35.6 Entry of Reception Rules (for Setting Channel 0 and 1): The page number in the reception rule table, modified (23 → 7)
		2066	35.9.1.4 Reception Rule Setting: The body, modified (pages 0 to 23 → pages 0 to 7)
		36. Serial Peripheral Interface (RSPIa)	
		2092	Figure 36.1 RSPI Block Diagram: The suffix "y" was added to interrupt names.
		2093	Table 36.2 RSPI Pin Configuration: The "Function" column for the SSL00, SSL01, SSL02, SSL03, SSL10, SSL11, SSL20, and SSL30 pins, modified
		2095	36.2.1 RSPI Control Register: "(i.e. the SPSR.SPTEF bit = 1)" in the description of the SPTIE bit, deleted
		2101	Figure 36.2 Configuration of SPDR: The description related to the shift register, modified
		2109	36.2.10 RSPI Clock Delay Register: The body, modified
		2115	36.2.14 RSPI Command Registers 0 to 7: Bit table: The description of "x", deleted
		2147	Figure 36.31 Procedure for Determining the Form of Serial Transfer in Master Mode: The pin name, modified (SSLA[2:0] → SSLy[2:0])
		2157	Figure 36.39 Example of Initialization Flowchart in Slave Mode (SPI Operation): The signal name, modified (SSLA0 input signal → SSL signals)
		2161	Figure 36.43 Procedure for Determining the Form of Serial Transmission in Master Mode: The pin name, modified (SSLA[2:0] → SSLy[2:0])
		2168	36.3.14 Interrupt Sources: The description of the transmission buffer empty and reception buffer full interrupts, deleted
		2171	36.5.2 Note on Low-Power Consumption Functions: The body, modified
		37. SPI Multi I/O Bus Controller (SPIBSC)	
		All	The name of the clock signal, modified (ICLK → PCLKA)
		2172	37.1 Overview: The body, modified
		2209	Table 37.5 Data Registers: The description of the dummy cycle, modified (DRDMC register → DRDMCR register, SMDMC register → SMDMCR register)
		2209	37.3.10, (2) Data Enable: The description, modified
		2213	Table 37.8 Pin Status (3): The erroneous pin name, corrected (SPBMI0/SPBIO10 → SPBMI/SPBIO1)
		38. CRC Operation Units (CRC)	
		2216	Figure 38.1 Block Diagram of a CRC Operation Unit (CRC): The erroneous bit symbol, corrected (CRCCR.DCR0POL[1:0] → CRCCR.DCRA0POL[1:0])
		2219	38.2.3 CRC Control Register: Bit table: The erroneous bit symbol, corrected (CRCCR → CRCDIR)
		39. Serial Sound Interface (SSI)	
		2223	Figure 39.1 Block Diagram of SSI: The name of the clock signal, modified (MCLK → MCLK(ACLK)); the interrupt-related description, modified (interrupt source → interrupt request)
		2226	Table 39.3 SSITXD and SSIRXD Pin States: "—: Settings prohibited.", deleted
		2229	39.2.2 Status Register: The description of the ROIRQ flag, modified
		2246	39.3.5 Transmit Operation: The body, modified
		40. Boundary Scan	
		2280	40.3.2 List of Commands: The instruction name, modified (EXTEXT → EXTEST); descriptions (2) and (3): Erroneous instruction code, corrected (0000 1111b → 0000b, 0100 1111b → 0100 0000b); the description in (4), modified

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	41. ΔΣ Interface (DSMIF)	
		2283	Table 41.1 DSMIF Specifications: The suffix "m" in the "Description" column for the "Functions" item, modified
		2304	41.2.22 XYZ Status Register: The erroneous register symbol, corrected (XYSTX register → XYZSTA register)
		2305	41.2.23 XYZ Overcurrent Abnormality Detection Lower Limit Setting Register: Bit table: The error in the "Symbol" column for b15 to b0, corrected
		2312	41.3 Operation: The body, modified
		2313	Figure 41.3 Configuration of the Decimator (Example of Channel 0 (U)): The symbol of the clock signal, modified (MCLKm → MCLK0)
		2314	Table 41.5 Decimation Clock Settings and Resolutions: Note 1, modified
		2315	Table 41.7 Decimation Clock Settings and Resolutions: Note 1, modified
		2316	41.3.3.3 Detection of Short-Circuit Abnormalities: The body, modified
		2317	41.3.4 Settings for Operating Clock Signals: The description of suffix "m" for MCLKm, modified
		2320	Figure 41.10 Operation when MCLKn is not Inverted: The name of clock signal, modified (MCLK(ΔΣIF) → MCLK with inversion applied)
		2320	Figure 41.11 Operation when MCLKn is Inverted: The name of clock signal, modified (MCLK(ΔΣIF) → MCLK with inversion applied)
		2321	41.5.2 Current Value on Detection of an Overcurrent: The body, modified
		42. Error Control Module (ECM)	
		All	The description of error sources, modified (long access wait state → timeout)
		2324	Table 42.2 ECM Error Input (1 / 2): The core name shown in the table, modified (Cortex-RF4 → Cortex-R4)
		2328	42.2.3 ECM Master/Checker Error Source Status Register 0: Bit table: The "Description" column for b4 (ECMmSSE004) and b5 (ECMmSSE005), modified
		2334	42.2.8 ECM Maskable Interrupt Configuration Register 0: Bit table: The "Description" column for b4 (ECMMIE004) and b5 (ECMMIE005), modified
		2339	42.2.11 ECM Non-maskable Interrupt Configuration Register 0: Bit table: The "Description" column for b4 (ECMNMIE004) and b5 (ECMNMIE005), modified
		2344	42.2.14 ECM Internal Reset Configuration Register 0: Bit table: The "Description" column for b4 (ECMIRE004) and b5 (ECMIRE005), modified
		2349	42.2.17 ECM Error Mask Register 0: Bit table: The "Description" column for b4 (ECMEMK004) and b5 (ECMEMK005), modified
		2354	42.2.20 ECM Error Source Status Clear Trigger Register 0: Bit table: The "Description" column for b4 (ECMCLSSE004) and b5 (ECMCLSSE005), modified
		2360	42.2.25 ECM Pseudo Error Trigger Register 0: Bit table: The "Description" column for b4 (ECMPE004) and b5 (ECMPE005), modified
		2367	42.2.31 ECM Delay Timer Configuration Register 0: Bit table: The "Description" column for b4 (ECMTE004) and b5 (ECMTE005), modified
		2373	42.2.34 ECM Delay Timer Configuration Register 3: Bit table: The "Description" column for b4 (ECMTE304) and b5 (ECMTE305), modified
		43. 12-Bit A/D Converter (S12ADCa)	
		2408	43.2.6 A/D-Converted Value Addition/Average Mode Select Register: The erroneous bit symbol in the description of the ADS[15:0] bits, corrected (ADANSA0.ANSA0[15:0] → ADANSA.ANSA[15:0])
		2419	43.2.13 A/D Sample and Hold Circuit Control Register: Bit table, modified (b15 to b11 (reserved) → b15 to b12 (reserved))
		2431	43.2.23 A/D Compare Status Extended Register: Address(es), modified
		2433	43.2.26 A/D Error Clear Register: Address(es): Module symbols, modified
		2434	43.2.27 A/D Overwrite Error Register: OWE[15:0] bits: Erroneous symbol, corrected (OWE0 → OWE)

Rev.	Date	Description	
		Page	Summary
1.50	Jan. 17, 2019	2473	43.3.6 Comparison: The description in (2), modified (ADCMPANSRy register → ADCMPANSR register)
		2484	43.4.1 Interrupt Requests: The body, modified (ADI and GBADI interrupts → S12ADI and S12GBADI interrupts)
		2484	Table 43.12 Relationship between Mode Setting and S12ADI Interrupt Output, modified (ADI interrupt → S12ADI interrupt, GBADI interrupt → S12GBADI interrupt)
		2488	43.5.6 Notes on Entering Low-Power Consumption States: The body, errorneous description corrected
		44. Temperature Sensor	
		2492	44.3.1 Preparation for Using the Temperature Sensor: The reference destination, modified
		2493	44.3.1 Preparation for Using the Temperature Sensor: The description titled “How to obtain the value for voltage to be output from the temperature sensor (when AD-converted value addition mode is not selected)”, added
		46. RAM (Product Option)	
		2503	46.1 Overview: Note, modified
		2505	46.2.2 ECC Decoder Configuration Register: The body, modified (the description for the cases of both 1-bit and 2-bit ECC errors, added)
		2511	46.2.6 2-Bit ECC Error Status Register: The body, modified
		2514	46.2.8 2-Bit ECC Error Address Register: Bit table: The erroneous description in the note, corrected; term unified (ECC 2-bit error → 2-bit ECC error)
		2515	46.2.9 2-Bit ECC Error Address Register: Bit table: The erroneous description in the note, corrected; term unified (ECC 2-bit error → 2-bit ECC error)
		2518	Figure 46.2 Example of ECC Error-Injection Setting Procedure: Figure title, added; the processing, modified
		2519	Figure 46.3 Procedure of Checking ECC Operation: Figure title, added; the processing, modified (DBE_IRQ interrupt → interrupt*1); note 1, added
		47. Electrical Characteristics	
		2521	Figure 47.1 Power On/Off Sequence: "Timing" table: "—" was added to the "Value (typ)" column for Nos (3), (4), and (5).
		2523	Table 47.3 DC Characteristics (2) [Power Supply] (1 / 2): VIcc when VDD is 300 MHz in normal operation, modified
		2526	Table 47.5 DC Characteristics (4) [USB2.0 USB_RREF Pin]: The "min" column, modified (200Ω ±1% → 200 ±1%); the "Ω" in the "Unit" column, added
		2530	Table 47.12 CLKOUT25Mn Timing, modified (CLKOUT25Mn (RMII): Tck → Tck1, CLKOUT25Mn (MII): Tck → Tck2)
		2530	Figure 47.3 CLKOUT25Mn Pin Output Timing 1: Symbols, modified
		2530	Figure 47.4 CLKOUT25Mn Pin Output Timing 2: Symbols, modified
		2531	Table 47.13 EXTAL Clock Timing: Time value, modified (40.00 + 50 ppm → 40.00 ± 50 ppm)
		2531	Table 47.14 XTAL Clock Timing: Time value, modified (40.00 + 50 ppm → 40.00 ± 50 ppm)
		2568	Table 47.24 GPTa Timing: The symbol, modified (T_{OTETW} → t_{GTEW})
		2572	Table 47.27 RSPIa Timing: Note 4, added
1.60	Nov. 30, 2020	All	Registered trademark symbol added (Arm → Arm®)
		All	Package name changed (HLQFP → HLFQFP)
		Features	
		55	Note 3 deleted (renumbering the subsequent note numbers: Note 4 → Note 3, Note 5 → Note 4)
		1. Overview	
		57	Table 1.1 Outline of Specifications (2 / 7): VIC, NVIC: Peripheral function interrupts: Number of sources, modified
		58	Table 1.1 Outline of Specifications (3 / 7): TPUa: The footnote number for the number of units, modified
		59	Table 1.1 Outline of Specifications (4 / 7): IWDTa: The unit of frequency, modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	66	Figure 1.1 Block Diagram: The number of MTU3a channels, modified
		69	Table 1.4 Pin Functions (3 / 7): MTU3a: The function of pins MTIOC0m to MTIOC8m, modified
		69	Table 1.4 Pin Functions (3 / 7): GPTa: The function of pins GTIOC0A, GTIOC0B to GTIOC3A, and GTIOC3B, modified
		71	Table 1.4 Pin Functions (5 / 7): ETHERC: The function of pin ETHSWSECOUT, modified
		75	Figure 1.3 Pin Arrangement (176-pin HLFQFP): Note 2 added
		3. Operating Modes	
		113	Figure 3.2 Memory Assignment of the Loader Program and Parameters for the Loader: Note 3 modified
		114	Table 3.3 Parameter Information for the Loader in 16-bit or 32-bit Bus Boot Mode: Note 3 modified
		115	Table 3.4 Parameter Information for the Loader in SPI Boot Mode: 0000 0018h/LDR_SIZE_NML: The footnote number (*3) added; Note 3 modified
		116	3.5.3 Loader Program: The description of storage address in the external memory in SPI boot mode, modified
		4. Address Space	
		126	Figure 4.1 Memory Map: Cortex-M3: Text modified (BitBand Alias Area0 (32 MB) → BitBand Alias Area0 (16 MB))
		127	Figure 4.2 Memory Map: Cortex-R4: The description of "Mirror area of extended internal SRAM" modified
		5. I/O Registers	
		All	"EtherPHY" was modified to "Ethernet PHY"
		129	5. I/O Registers: The description modified
		205	Table 5.1 List of I/O Registers (Address Order) (76 / 86): Address A00B 0028h: The register name modified
		6. Reset	
		218	6.2.1 Reset Status Register 0 (RSTSR0): R/W in the table of bits, modified (R(/W) → R/(W))
		220	6.2.3 Software Reset Register 2 (SWRR2): Address(es) modified: (SWRR21 → SWRR2)
		221	6.3.4 Software Reset 2 (for products incorporating an R-IN engine): The register symbol modified (SWPR2 register → SWRR2 register)
		7. Clock Generation Circuit	
		224	7.1 Overview: The description modified
		227	Figure 7.1 Block Diagram of Clock Generation Circuit: Bus lines added
		228	Figure 7.2 Block Diagram of Clock Generation Circuit (for products incorporating an R-IN engine): Bus lines added
		229	Table 7.3 Pin Configuration of Clock Generation Circuit: The "Description" column, modified (EtherPHY → Ethernet PHY)
		237	7.2.5 PLL1 Control Register 2 (PLL1CR2): Table of bits: Note 1 modified
		239	7.2.7 Oscillation Stop Detection Control Register (OSTDCR): Table of bits: Note 1 modified
		242	7.4.1 Oscillation Stop Detection and Operation after Detection: The description modified
		243	7.8.2 System Clock (ICLK): The description modified
		243	7.8.3 High-Speed Peripheral Module Clock (PCLKA): The description modified
		243	7.8.4 Low-Speed Peripheral Module Clock (PCLKB): The description modified
		243	7.8.5 High-Speed Peripheral Module Clock (PCLKC): The description modified
		244	7.8.6 Low-Speed Peripheral Module Clocks (PCLKD, PCLKE, PCLKF, PCLKG, and PCLKH): The description modified
		244	7.8.9 USB Clock M (USBMCLK): The description modified
		244	7.8.10 USB Clock P (USBPCLK): The description modified
		244	7.8.11 Ethernet Clocks (ETCLKA, ETCLKB, ETCLKC, ETCLKD, ETCLKE, ETCLKF, and ETCLKG): The description modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	244	7.8.12 CLMA Clock (CLMAMCLKA, CLMAMCLKB, CLMALCLK, CLMAPLCLK0, and CLMAPLCLK1): The description modified
		246	7.9.1 Notes on Clock Generation Circuit: The descriptions in (4), (6), (7), and (9), modified
		8. Clock Monitor Circuit (CLMA)	
		253	8.3.1 CLMAn Operation, (1) Enabling operations: The description in step 3, modified
		256	8.3.2 Detecting Error Clock Frequency, (2) Method of calculating threshold values, CLMAnCMPL.CLMAnCMPL[11:0] and CLMAnCMPH.CLMAnCMPH[11:0], Example: For CLMA0: The upper-limit threshold, modified
		9. Low-Power Consumption Function	
		All	RIICa Unit → RIICa channel, SCIFA Unit → SCIFA channel, RSPIa Unit → RSPIa channel
		262	9.2.2 Module Stop Control Register B (MSTPCRB): Table of bits: The footnote number (*1) added to "b18, b19"
		10. Debugging Interface	
		284	10.3.6 Handling of JTAG Pins When No Emulator Is Connected: The title and description, modified
		284	Table 10.9 Handling of JTAG Pins When No Emulator Is Connected: The title and header, modified
		12. Interrupt Controller (ICUA)	
		289	Figure 12.1 Block Diagram of Interrupt Controller: Text modified: DMA0SELi, DMA1SELi, CDSEL → DMA0SELi, DMA1SELi (CDSEL deleted)
		289	Figure 12.2 Block Diagram of Interrupt Controller (for products incorporating an R-IN engine): Text modified: DMA0SELi, DMA1SELi, CDSEL → DMA0SELi, DMA1SELi (CDSEL deleted)
		298	12.2.9 Ethernet PHY Control Register i (EPHYCRi): "EtherPHY" was modified to "Ethernet PHY"
		304	12.3.1 Selecting Interrupt Request Destinations: The description modified
		307	12.3.3 External Pin Interrupts: The description modified
		308	12.3.4 NMI Pin Interrupts: The description modified
		309	12.4.1 Overview: The description modified
		320	12.4.2.3 Interrupt Enable Register n (IENn) (n = 0 to 9): The title modified (Interrupt Enable Register 0 → Interrupt Enable Register n)
		358	12.4.2.16 Interrupt Address Store Register 0 (VADn), Interrupt Address Store Register 1 (VADn): Bit chart: VADn[31:0] entered
		358	12.4.2.16 Interrupt Address Store Register 0 (VADn), Interrupt Address Store Register 1 (VADn): Table of bits: The symbol and functional description, modified
		358	12.4.2.16 Interrupt Address Store Register 0 (VADn), Interrupt Address Store Register 1 (VADn): The description of "VADn[31:0] Bit": The bit symbol, index, and description, modified
		367	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (3 / 10): The request sources modified: RSPI unit 0 to RSPI unit 3, SCIFA unit 0 → RSPI ch0 to RSPI ch3, SCIFA ch0
		368	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (4 / 10): The request sources modified: SCIFA unit 1 to SCIFA unit 4, RIIC unit 0, RIIC unit 1 → SCIFA ch1 to SCIFA ch4, RIIC ch0, RIIC ch1
		372	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (8 / 10): The sources of vector numbers 242 and 243, modified
		373	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (9 / 10): The source of vector number 259, modified
		376	Figure 12.6 Initializing Registers of VIC: Indices (m, q, r) modified
		378	Figure 12.8 Register Rewrite Flow: Text modified (IECm, IENm → IECn, IENn)
		381	12.4.4.3 Detecting Interrupts, (3) IRQ Interrupt (Edge Interrupt): The description modified
		381	Figure 12.10 IRQ Interrupt Operation (Edge Interrupt): Text modified (PICm → PICn)
		385	Figure 12.12 IRQ Interrupt Operation by Polling (Edge/Level Detection): Text modified (IENm → IENn)

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	390	Table 12.6 CM3 Interrupt Vector Table (2 / 4): The request sources modified: SCIFA unit 0, SCIFA unit 1, RIIC unit 0, RIIC unit 1 → SCIFA ch0, SCIFA ch1, RIIC ch0, RIIC ch1
		391	Table 12.6 CM3 Interrupt Vector Table (3 / 4): The request sources modified: RSPI unit 0, RSPI unit 1 → RSPI ch0, RSPI ch1
		13. Internal Buses	
		396	Figure 13.2 Internal Bus Configuration (for products incorporating an R-IN engine): The title modified
		14. Bus State Controller	
		408	14.3.2 CSn Space Wait Control Register (CSnWCR), (1) Normal Space, SRAM with Byte Selection, and MPX-I/O, CS1WCR: The bit names and functional descriptions of b1, b0 and b12, b11, modified (CSn# → CS1#)
		438	Figure 14.5 Example of 32-Bit Data-Width SRAM Connection: Text modified (OE → OE#)
		439	Figure 14.6 Example of 16-Bit Data-Width SRAM Connection: Text modified (OE → OE#)
		439	Figure 14.7 Example of 8-Bit Data-Width SRAM Connection: Text modified (OE → OE#)
		442	14.4.4 CSn# Assert Period Expansion: Note added
		472	Figure 14.28 Auto-Refresh Timing: Text modified (Hi-z → Hi-Z)
		473	Figure 14.29 Self-Refresh Timing: Text modified (Hi-z → Hi-Z)
		447	14.4.6 SDRAM Interface, (12) Low-Power SDRAM: The description modified
		482	14.4.8 SRAM Interface with Byte Selection: The description modified (UB → UB#, LB → LB#)
		485	Figure 14.38 Example of Connection with 32-Bit Data-Width SRAM with Byte Selection: Text modified (OE → OE#, UB → UB#, LB → LB#)
		485	Figure 14.39 Example of Connection with 16-Bit Data-Width SRAM with Byte Selection: Text modified (OE → OE#, UB → UB#, LB → LB#)
		487	14.4.10 Wait between Access Cycles: The description modified
		15. DMA Controller (DMACAa)	
		All	"display" was modified to " indicate"
		491	15. DMA Controller (DMACAa): The description modified
		491	Table 15.1 Specifications of DMAC: The descriptions of "Channel priority" and "Transfer mode/ Block transfer", modified
		549	15.3.4.1 Specifying Detection Operation of DMA Transfer Requests for Each Source: The description modified
		552	Table 15.21 DMA Transfer Request Detection Operation Setting Table (3 / 6): The DMA transfer request sources modified: RSPI Unit 0 to RSPI Unit 3, SCIFA Unit 0 to SCIFA Unit 3 → RSPI Channel 0 to RSPI Channel 3, SCIFA Channel 0 to SCIFA Channel 3
		553	Table 15.21 DMA Transfer Request Detection Operation Setting Table (4 / 6): The DMA transfer request sources modified: SCIFA Unit 4, RIIC Unit 0, RIIC Unit 1 → SCIFA Channel 4, RIIC Channel 0, RIIC Channel 1
		555	Table 15.21 DMA Transfer Request Detection Operation Setting Table (6 / 6): The DMA transfer sources of ELC, modified
		573	Table 15.25 DMA Transfer Setting Example 1: The item modified: DMA transfer completion interrupt mask → DMA transfer completion interrupt output mask
		575	Table 15.26 DMA Transfer Setting Example 2: The item modified: DMA transfer completion interrupt mask → DMA transfer completion interrupt output mask
		577	Table 15.27 DMA Transfer Setting Example 3: The item modified: DMA transfer completion interrupt mask → DMA transfer completion interrupt output mask
		583	Figure 15.44 Setting Example of Next Register Continuous Execution: The title modified
		16. Event Link Controller (ELC)	
		588	Figure 16.1 ELC Block Diagram: Title: Index (n), modified
		590	Table 16.2 Correspondence between the ELSRn Register and the Peripheral Functions: The entries under "Peripheral Function (Module)" for ELSR18 and ELSR19, modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	591	Table 16.3 Correspondence between Event Signal Names Set in ELSRn.ELS[7:0] Bits and Signal Numbers (1 / 3): The entry under "Name of Event Signal Set in ELSRn" for 22h, modified
		607	Figure 16.2 Relation between Interrupt Handling and ELC (excluding the Ethernet MAC and EtherCAT): Text modified (ICU → ICUA)
		608	Table 16.5 Operations of Modules When Event is Input: MTU, CMT, CMTW, TPU, GPT modules: The description under "Operations When Event is Input" modified
		609	16.3.3 Operation of Peripheral Timer Modules When Event is Input: The description modified
		610	Figure 16.3 Event Linkage Related to Single Ports (Port B): The titles of [1] and [2], modified
		611	16.3.5 I/O Port Operation upon Event Input and Event Generation, (5) Input Port Group Operation upon Event Input: The description of the figure for reference, modified; the description when PGCn.PGCOVEn = 0, modified
		611	Figure 16.4 Input Port Group Operation upon Event Input (Port B): The direction of the text "Levels input on the pins", modified; text modified
		612	16.3.5 I/O Port Operation upon Event Input and Event Generation, (6) Output Port Group Operation upon Event Input: The description "while the PGCn.PGCOn bit being 1XXb", modified
		614	16.3.6 Example of Procedure for Linking Events: The description in step 4, modified
		615	16.4.1 Setting ELSR18 and ELSR19 Registers: The description added
		17. I/O Ports	
		All	"Hi-z" was modified to "Hi-Z"
		618	Figure 17.1 I/O Port Configuration (1): Note 1 modified
		619	Figure 17.2 I/O Port Configuration (2): Note 1 modified
		620	Figure 17.3 I/O Port Configuration (3): Note 1 modified
		621	Figure 17.4 I/O Port Configuration (4): Note 1 modified
		623	17.3.1 Port Direction Register (PDR): Address(es) modified: PORT0 PDR → PORT0.PDR
		625	17.3.3 Port Input Data Register (PIDR): The title modified
		627	17.3.5 Pull-Up/Pull-Down Control Register (PCR): The title modified
		629	17.4 Handling of Unused Pins: The description modified
		18. Multi-Function Pin Controller (MPC)	
		All	18.2 Register Descriptions: The description in each subsection modified: "Modify the register after releasing the protection." → "Modifications to this register can only be made after releasing protection."
		662	18.2.8 P6n Pin Function Control Register (P6nPFS): The description modified
		667	18.2.11 P9n Pin Function Control Register (P9nPFS): The description of "ISEL Bit", modified
		676	18.2.16 PEn Pin Function Control Register (PEnPFS) (n = 0 to 7): The description of "ISEL Bit", modified
		685	18.2.24 PNn Pin Function Control Register (PNnPFS): The description modified
		686	18.2.25 PPn Pin Function Control Register (PPnPFS): The description modified
		19. Multi-Function Timer Pulse Unit (MTU3a)	
		719	Table 19.15 TIOR (MTU1): The functional description of the MTIOC1B pin when IOB[3:0] = 111x, modified
		724	Table 19.25 TIORH (MTU8): The entries under IOB[3:0] modified: 1x00, 1x01, 1x1x, 11xx → 1000, 1001, 101x, 11xx
		810	19.3.6 Phase Counting Mode: The description in the case of 32-bit phase counting mode, modified
		830	Figure 19.46 Block Diagram of MTU3 and MTU4 in Complementary PWM Mode: External cutoff input: POE11#, deleted
		831	Figure 19.47 Block Diagram of MTU6 and MTU7 in Complementary PWM Mode: External cutoff input: POE11#, deleted
		20. Port Output Enable 3 (POE3)	
		982	Table 20.5 Correspondence between MTU and GPT Pins: Note 2 modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	21. General PWM Timer (GPTa)	
		988	Table 21.1 Specifications of GPT: The description of the module-stop state, modified
		1005, 1006	21.2.12 General PWM Timer I/O Control Register (GTIOR): The description of "OAHLD Bit": [When the OAHLD bit is set to 0], modified; the description of "OBHLD Bit": [When the OBHLD bit is set to 0], modified
		22. 16-Bit Timer Pulse Unit (TPUa)	
		1149	22.2.9 Timer Synchronous Register (TSYRA, TSYRB): The description modified
		1150	22.2.10 Noise Filter Control Register (NFCR): Table of bits: Note 1 modified
		1157	Figure 22.7 Example of Setting Procedure for Waveform Output by Compare Match: The description in [1]: Index modified
		1159	22.3.1 Basic Functions, (3) Input Capture Function: Index modified
		1167	22.3.4 Cascaded Operation: Note 2 modified
		1169	22.3.5 PWM Modes: 1. PWM mode 1: The description modified; 2. PWM mode 2: The description modified
		1180	Figure 22.32 Timing Chart for the Noise Filter: Text modified (Input-capture input → Input-capture input pin)
		1182	Figure 22.33 Connection Diagram of Example Setting for PWM 1-Axis Measurement: Text modified
		1184	Figure 22.34 Connection Diagram of Example Setting for PWM 2-Axes Measurement: Text modified
		1186	Figure 22.35 Connection Diagram of Example Setting for PWM 1-Axis Measurement: Text modified
		1188	Figure 22.36 Connection Diagram of Example Setting for PWM 2-Axes Measurement: Text modified
		1191	22.5 DMAC Activation: The description modified
		1209	22.10.2 Receiving an Event Signal from ELC, (2) Clear Counting: The description modified
		1210	22.10.2 Receiving an Event Signal from ELC, (3) Input Capture Operation: The description modified
		1212	Figure 22.67 Conflict between TGRy Read Cycle and Input Capture Operation: Text modified
		23. Programmable Pulse Generator (PPG)	
		1238	Figure 23.11 Inverted Pulse Output (Example): Text modified (PODRL → PODRH)
		1239	23.3.8 Pulse Output Triggered by Input Capture: The description modified
		24. Compare Match Timer (CMT)	
		1247	Figure 24.5 Timing of Event Issuance: Text modified (CMCNTn → CMT1.CMCNT, CMCORn → CMT1.CMCOR)
		1248	24.5.2 CMT Operation When Receiving an Event from ELC, (1) Count Start: The bit symbol, modified
		1249	24.5.2 CMT Operation When Receiving an Event from ELC, (2) Event Count: The register name, modified
		1250	24.5.2 CMT Operation When Receiving an Event from ELC, (3) Count Clear: The description modified
		1251	24.5.3 Notes on CMT Event Link Operation, (1) Count Start: The register name, modified
		1252	24.5.3 Notes on CMT Event Link Operation, (2) Event Count: The register symbol, modified
		1253	24.5.3 Notes on CMT Event Link Operation, (3) Count Clear: The register symbol, modified
		25. Compare Match Timer W (CMTW)	
		1256	Table 25.1 Specifications of CMTW, Low-power consumption function: The functional description modified
		1263	25.2.5 Compare Match Constant Register (CMWCOR): The description modified
		1266	25.2.9 Digital Noise Filter Control Register 1 (NFCR1): The description modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	1267	25.2.10 ECM Dynamic Mode Error Output Select Register (ECDMESLR): Table of bits: The description of "b2 to b0", modified
		1282	25.6.1 Module-Stop Function: The description modified
		26. Watchdog Timer (WDTA)	
		1290	26.1 Overview: The redundant description deleted
		1296	26.2.3 WDT Status Register (WDTSR): The description modified; Table of bits: R/W of "b14, b15", modified
		1298	26.3.1.1 Register Setting: The description modified
		1301	26.3.3 Refresh Operation, [Sample sequences of writing that are not valid for refreshing the counter]: The typo corrected
		1304	26.4.1 Watchdog Timer Operations in Low-Power Consumption Mode Transition: The title and description, modified
		1304	Table 26.4 WDT Operations during Transition to Low-Power Consumption Mode <in Low-Power Consumption Mode Transition>: The title modified
		27. Independent Watchdog Timer (IWDTa)	
		1305	Table 27.1 IWDT Specifications: The item "Sources for the output of error notification to ECM", modified; The description of "Reading the counter value", modified
		1312	27.2.3 IWDT Status Register (IWDTSR): The description modified
		1317	27.3.3 Refresh Operation, [Sample sequences of writing that are not valid for refreshing the counter]: The typo corrected
		1322	27.4.1 Watchdog Timer Operations in Low-Power Consumption Mode Transition: The title modified
		1322	Table 27.4 IWDT Operations during Transition to Low-Power Consumption Mode <in Low-Power Consumption Mode Transition>: The title modified
		28. Ethernet MAC (ETHERC)	
		1323	28. Ethernet MAC (ETHERC): The description modified
		1324	28.1 Overview: The description modified
		1325	Table 28.2 Input/Output Pins of the ETHERC: The functional description of the ETHSWSECOUT signal, modified
		1326	28.1 Overview: The tables for reference, modified
		1326	Table 28.3 I/O Pin Functions for ETHERC (in MII mode): The title and the table of "Others", modified
		1326	Table 28.4 I/O Pin Functions for ETHERC (in RMII mode), added
		1330	28.2.1.4 MAC Select Register (MACSEL): The figure and table for reference in the description modified; Table of bits: The table for reference in the functional description of "b2 to b0", modified
		1333	28.2.2.1 MIIM Register (GMAC_MIIM): Note modified
		1337, 1338	28.2.2.5 RX MODE Register (GMAC_RXMODE): The functional descriptions of "b11 to b9" and "b29", modified
		1361	Figure 28.4 Flow of Processing for Issuing the Hardware Function Call: Processing of "Disable HW-RTOS interrupts (HWRTOS)" and "Enable HW-RTOS interrupts (HWRTOS)" added; Note 1 added; Note 1 changed to Note 2
		1362	28.3.1.3 Buffer Allocator, (1) Functional Overview: The description modified
		1365	Table 28.8 HWFNC_LongBuffer_Get: Return value register R1, modified
		1366	Table 28.9 HWFNC_ShortBuffer_Get: Return value register R1, modified
		1371	28.3.1.4 MAC DMA Controller. (2) DMA for the reception MAC, (a) Description of the individual functions of the MAC DMA controller, 1-5) Judging whether a received frame is valid or invalid: The missing description added
		1372	28.3.1.4 MAC DMA Controller, (2) DMA for the reception MAC, (b) Usage: Example of reading and releasing a buffer, modified
		1373	28.3.1.4 MAC DMA Controller, (2) DMA for the reception MAC, (c) List of hardware function calls: The description modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	1378	28.3.1.4 MAC DMA Controller, (3) DMA for the transmission MAC, (d) List of hardware function calls: The description modified
		1379	Table 28.17 HWFNC_MACDMA_TX_Errstat: Return value register R0. modified
		1381	Table 28.18 HWFNC_Direct_Memory_Transfer: Argument registers R4 and R5, modified
		1383	Table 28.20 Interrupts related to Operations for Transmission: MACDMA transmission error interrupt (ETHDTIE): The condition for asserting and de-asserting interrupts, modified
		29. Ethernet Switch	
		1421	29.2.2.5 Input Learning Blocking Register (INPUT_LEARN_BLOCK): Table of bits: The typos in the functional descriptions of b16, b17, and b18, corrected
		1452	29.2.5.3 Port Timestamp Control/Status Register (PORTn_CTRL): Table of bits: The typos in the functional description of b0, corrected
		1453	29.2.5.4 Port Timestamp Register (PORTn_TIME): Address(es): The registers modified
		1491	Table 29.2 Operations of the Hub and Switch by Filter Settings: Note 1 and Note 3, modified
		1495	29.3.3.1 Beacon Frame Format: The description modified
		1507	29.3.4.3 Adjustable Timer Module, (6) Pulse Signal Generation: The description modified
		1509	29.3.5 Frame Tag Dedicated to Management Port (Internal Port): The typos corrected (MCA → MAC)
		1516	29.4.3.2 Address Learning: The description modified
		30. EtherCAT Slave Controller	
		1540	30.8.2 AL Status Register (AL_STATUS): Table of bits: The functional description of b5, modified
		1560	30.14.1 MII Management Control/Status Register (MII_CONT_STAT): The description of write access and Note: Bit notation "b" added
		1599	30.18.5 Setting the Module-Stop Function: The typo corrected (MSTPCRB5 → MSTPCRB15)
		31. USB2.0HS Host Module (USBh)	
		1710	Figure 31.13 Initial Setting Sequence: The typo corrected (OVERCUR → OVRCUR)
		32. USB 2.0 HS Function Module (USBf)	
		1788	Figure 32.4 Startup Sequence: The typo corrected (BUSIN → VBUSIN)
		33. Serial Communications Interface with FIFO (SCIFA)	
		1820	33.2.7 Serial Status Register (FSR): The description of "DR Bit", modified (Note 2 → Note)
		1837	33.3.1 Overview: The description modified
		1843	Figure 33.4 Sample Flowchart for Transmitting Serial Data in Asynchronous Mode: The description in [2], modified
		1848	Figure 33.10 Example of SCIFA Receive Operation in Asynchronous Mode Using Modem Control Function (RTS#): The typo in the title, corrected
		1851	Figure 33.13 Sample Flowchart for Transmitting Serial Data in Clock Synchronous Mode: The description in [2], modified
		1855	Figure 33.17 Sample Flowchart for Simultaneous Transmitting/Receiving Serial Data in Clock Synchronous Mode: The description in [2], modified
		34. I^2C Bus Interface (RIICa)	
		1892	34.2.14 I^2C Bus Bit Rate High-Level Register (ICBRH): Note 1 modified
		1907	34.3.5 Slave Transmit Operation: The description in (1), modified (slave mode → slave reception mode)
		1910	34.3.6 Slave Receive Operation: The description in (1), modified (slave receive mode → slave reception mode)
		1913	Figure 34.21 Generation and Synchronization of the SCL Signal from the RIIC: Text modified (SCL0n line → SCLn line)
		1914	Figure 34.22 SDA Output Delay Facility: [Transmission mode]: SCLn modified
		1915	Figure 34.23 Block Diagram of Digital Noise Filter Circuit: Text modified (SCL0n/SDA0n → SCLn/SDAn)

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	1928	Figure 34.34 Example of Arbitration-Lost Detection during Transmission of NACK (NALE = 1): Text modified (Release SCLn/SDA → Release SCL/SDA)
		1929	Figure 34.35 Example of Slave Arbitration-Lost Detection (SALE = 1): Text modified (Release SCLn/SDA → Release SCL/SDA)
		1936	Table 34.6 Interrupt Sources: Note 1 and Note 2 switched; a part of the description in Note 1 and Note 2, deleted
		35. CAN Interface (RSCAN)	
		1962	35.2.9 Global TX Interrupt Status Register 0 (RSCAN0GTINTSTS0): The descriptions of "TSIFm Bits" and "TAIFm Bits", modified: TMTRF[1:0] flags → TMTRF[1:0] flag
		1970	35.2.16 Reception Rule Pointer 1 Registers (RSCAN0GAFLP1j): The title of the bit description modified: "GAFLFDPr [25:0] Bits" → "GAFLFDP[17:0] and GAFLFDPr[7:0] Bits"
		1972	35.2.18 Reception Buffer New Data Register 0 (RSCAN0RMND0): Table of bits: "b31 to b16" and "b15 to b0" switched; the bit description modified: "RMNSq_h, RMNSq_l Flags" → "RMNSq_l, RMNSq_h Flags"
		1980	35.2.24 Reception FIFO Buffer Status Registers (RSCAN0RFSTSx): The description of "RFMC[7:0] Flag" modified: Flags → Flag
		2001	35.2.38 FIFO Full Status Register (RSCAN0FFSTS): In the table of bits, R/W of "b31 to b14" modified
		2022	35.2.56 Transmission Queue Pointer Control Registers (RSCAN0TXQPCTRm) (m = 0, 1): The typo in the description of "TXQPC[7:0] Bits", corrected
		2048	Table 35.17 Registers Initialized in Global Reset Mode or Channel Reset Mode: Note 3 modified
		36. Serial Peripheral Interface (RSPIa)	
		2100	36.2.4 RSPI Status Register (SPSR): Table of bits: The functional description and R/W of "b4 to b7", modified
		2110	36.2.10 RSPI Clock Delay Register (SPCKD): The description modified
		39. Serial Sound Interface (SSI)	
		2230	39.2.2 Status Register (SSISR): The description of "ROIRQ Flag", modified
		2247	39.3.5 Transmit Operation: The description modified
		40. Boundary Scan	
		2257	40.2.4 Boundary Scan Register (JTBSR): The description modified
		2261	Table 40.5 Boundary Scan Register (320FBGA) (4 / 14): The pin number of P25 corrected (T14 → Y14)
		2272 to 2278	Table 40.6 Boundary Scan Register (176HLQFP): The title modified: 176QFP → 176HLFQFP
		2281	40.3.2 List of Commands, (3) SAMPLE/PRELOAD [Instruction Code: 0100 0000b]: The instruction name modified: "TXTEST instruction" → EXTEST instruction"; a part of the description modified
		2282	40.4 Usage Notes: The description in 12., modified
		41. ΔΣ Interface (DSMIF)	
		2313	41.3 Operation: The description modified
		2314	41.3.2 Decimation: The description modified: "WORD1GEN[1:0]" → "WORD1GEN[2:0]", WORD2GEN[1:0] → WORD2GEN[2:0]
		2315	Table 41.5 Correspondence between BITSHIFT1[3:0] Settings and 16-Bit Values for Current: The title and header, modified
		2316	Table 41.7 Correspondence between BITSHIFT2[3:0] Settings and 16-Bit Values for Current: The title and header, modified
		2319	Figure 41.8 Relationship between the Settings for Filtering and the Format of Values for Current: The settings in (a) and (b), modified
		2322	41.5.2 Current Value on Detection of an Overcurrent: The description modified
		42. Error Control Module (ECM)	
		All	42.2 Registers: Table of bits: The functional descriptions of reserved bits (R/W) and (W), modified

Rev.	Date	Description	
		Page	Summary
1.60	Nov. 30, 2020	2327	42.2.1 ECM Master/Checker Error Set Trigger Register (ECMmESET (m = M or C)): Table of bits: Note 1 modified
		2352	42.2.17 ECM Error Mask Register 0 (ECMEMK0): Table of bits: The functional descriptions of b23 and b24. modified
		43. 12-Bit A/D Converter (S12ADCa)	
		All	Pin names modified: ANEX0 → AN1_ANEX0, ANEX1 → AN1_ANEX1
		2404	Table 43.4 Relationship between DBLANS Bit Settings and Double Trigger Enabled Channels: Note added
		2406	Table 43.5 Selectable Targets for A/D Conversion Depending on the Settings of Scan Mode and Double Trigger Mode: "Group scan": The entry under "Self-Diagnosis" when DBLE = 1, modified
		2443	43.3.2.6 A/D Conversion in Double Trigger Mode: The description modified
		2443	Figure 43.9 Example of Operation in Single Scan Mode (Double Trigger Mode Selected: AN003 Duplicated; TRG4ABN Selected as Trigger; Self-Diagnosis Deselected): The title modified
		2485	Table 43.12 Relationship between Mode Setting and S12ADI Interrupt Output: "Single scan mode": The entries when DBLE = 1, modified; "Group scan mode": The entries when DBLE = 0 and DBLE = 1, modified: Note 1 modified
		2490	43.5.10 Caution When Using Self-Diagnosis: The description modified
		44. Temperature Sensor	
		2494	44.3.1 Preparation for Using the Temperature Sensor: The description of the output voltage and the description in "Remark", modified
		2496	Table 44.2 Time until Completion of A/D Conversion after the Start of Temperature-Sensor Operation: The times of tSAM and tED, modified
		47. Electrical Characteristics	
		2526	Table 47.4 DC Characteristics (3) [Except for USB2.0 Host/Function-Related Pins] The footnote number added: Three-state leakage current (off state) / 5-V tolerant pins / $\|I_{TSI}\|$ → Three-state leakage current (off state) / 5-V tolerant pins*1 / $\|I_{TSI}\|$
		2531	Table 47.12 CLKOUT25Mn Timing: CLKOUT25Mn (RMII) / CLKOUT25Mn frequency, CLKOUT25Mn (MII) / CLKOUT25Mn frequency: The max. and min. values modified; index (n = 0 to 2) added
		2537	Table 47.17 Bus Timing (2 / 2): The border under "tWTS", deleted
		2543	Figure 47.17 SRAM Bus Cycle with Byte Selection (SW = 1 Cycle, HW = 1 Cycle, Asynchronous External Wait 1 Inserted, BAS = 0 (Write Cycle UB#/LB# Control)): The title modified
		2544	Figure 47.18 SRAM Bus Cycle with Byte Selection (SW = 1 Cycle, HW = 1 Cycle, Asynchronous External Wait 1 Inserted, BAS = 1 (Write Cycle WE# Control)): The title modified
		2565	Figure 47.41 TPUa Clock Input Timing: Text modified (TCLK0A to TCLK0D, TCLK1A to TCLK1D → TCLKA to TCLKD)
		2568	Figure 47.45 POEn# Input Pulse Timing: Index (n = 0, 4, 8, 10), added
		2574	Figure 47.53 RSPIa Timing (Master, CPHA = 0): Changed to the correct figure
		2581	Table 47.29 RIICa Timing: Note 4 modified
		2586	Table 47.32 ETHERC Timing: Index (n = 0 to 2), added
		2590	Table 47.33 Serial Management Interface: The entries modified (ETHn_MDC, ETHn_MDIO → ETH_MDC, ETH_MDIO; Note added
		2594	Table 47.36 On-chip USB High-Speed Characteristics (USB_DP, USB_DM Pin Characteristics): The header notation modified (Typ → typ)
		Appendix 1. Outer Dimensions Diagram	
		2602	Figure B 176-Pin HLQFP (PLQP0176LD-A), modified
1.70	Jan. 31, 2022	12. Interrupt Controller (ICUA)	
		373	Table 12.3 Cortex-R4/DMAC Interrupt Vector Table (9/10): RIIC Unit0 → RIIC ch0, RIIC Unit1 → RIIC ch1
		15. DMA Controller (DMACAa)	
		513	15.2.13 Channel Configuration Register n (CHCFG_n): Note 2, added

Rev.	Date	Description	
		Page	Summary
1.70	Jan. 31, 2022	33. Serial Communications Interface with FIFO (SCIFA)	
		1820	33.2.7 Serial Status Register (FSR): The description in "DR Bit (Receive Data Ready Flag)", modified. Note 2, added.
		1860	33.7 Noise Cancellation: base clock (the clock with a frequency 16 or 8 times the transfer rate) → base clock (the clock with a frequency 16, 8, or 4 times the transfer rate) Note 1, modified
